COROT—DESERONTO

COROT, kô-rô', Jean Baptiste Camille, French painter: b. Paris, July 17, 1796; d. there, Feb. 22, 1875. Against the wishes of his family he studied art, first under Claude Michallon, next under Victor Bertin, and then in 1825 went to Italy, where he returned on two other occasions, in 1835 and 1843. In 1827 he first exhibited in the Salon in Paris, not gaining his great popularity, however, until 20 years later. The last 25 years of his life were spent in affluent circumstances (his professional income being immense, and his father's death having brought him a large fortune) and in the happiness engendered by success. In 1867 he was made an officer in the Legion of Honor.

One of the painters of the so-called Barbizon School, Corot excelled in landscape painting. He was a diligent student of nature, whose aspect he idealized on canvas in sober tints of brown, pale green, and silver grays. After 1850 his classical treatment of nature changed to a more "atmospheric" treatment, and he became pre-eminently successful with his scenes in the faint lights of dawn and twilight, behind a transparent veil of mist, the early rays glinting through the dense foliage, mirrored in sparkling water. His aim in this style is expressed by his words: "In our search for truth and exactitude of form let us never forget to give it that atmospheric envelopment that impresses us." Examples of his earlier work are *Narni Bridge* (1827, Louvre) and *Chartres Cathedral* (1830, Louvre), while his later style is represented by such paintings as *Dance of the Nymphs* (1851, Louvre) and *Recollection of Montfontaine* (1864, Louvre). He is also noted for his figure paintings, highly regarded of which are *La Zingara* (1865, Louvre) and *Woman with the Pearl* (1868, Louvre).

Among his other works may be mentioned *Martyrdom of Saint Sebastian* (1853); *Morning* (1855); *Evening* (1855); *Sunset* (1857); *Orpheus* (1861); *Rest* (1861); *Solitude* (1866); *Landscape with Figures* (1870); and *Pleasures of Evening*. Several of his works are in public and private galleries of America.

COROZAL, kô-rô-säl', town and municipality, Puerto Rico, in the north central part of the island, about 16 miles directly southwest of San Juan. It is a tobacco and fruit growing area and its chief industries are fruit and vegetable can-

ning. Deposits of gold, platinum, manganese, and copper are located nearby. Pop. (1950): town, 2,432; municipality, 23,080.

COROZO NUT. See **VEGETABLE IVORY**.

CORPORAL, in the army, a noncommissioned officer with rank under that of a sergeant. He has charge of small bodies of men, usually squads. In the British army there are also soldiers distinguished by the designation of lance corporal, who are privates acting as corporals but receiving only privates' pay. In the British household cavalry the sergeants are called corporals of horse and the sergeants major, corporals major. This is a survival of the organization of the 16th and 17th century cavalry.

In the United States army a corporal is the lowest noncommissioned officer. His especial duty is to place and relieve sentinels. The corporal wears two chevrons on his sleeve as a mark of his rank, the lance corporal one only.

A ship's corporal was an officer who had the charge of setting and relieving the watches and sentries and who later became identified with the master-at-arms.

CORPORAL, the linen cloth laid on the altar, on which the sacred vessels are set during the consecration of the elements of bread and wine in the Mass or Holy Communion. It is to be distinguished from the veil, which is used to cover the chalice and paten, and the palla or pall. Both corporal and palla must be blessed and when not in use are carried in the burse, a square pocket of cardboard covered with silk; none except those in holy orders being allowed to touch them when they are in use.

CORPORAL, The Little. A term of affection applied to Napoleon Bonaparte by the soldiers of his Grande Armée, who always remembered that he began his career as a *sous-lieutenant* in Corsica.

CORPORAL PUNISHMENT, punishment applied to the body of the offender. In its connection with civil government it technically includes flogging, imprisonment and the death penalty, but in common parlance its meaning is more restricted and refers only to flogging or whipping of the body. Various extreme and cruel methods of punishment once in vogue have been discontinued in Christian nations, but

needy and to enrich and ennoble humanity which is not to a great extent done through the instrumentality of corporations."

In 1922 nearly one-third of all the wealth in the United States was controlled by corporations. The Federal Trade Commission concluded that the total wealth in that year was fully \$353,000,000,000 and placed the wealth controlled by corporations at \$102,000,000,000. Seager and Gulick in 'Trust and Corporation Problems' made the statement in 1929: "Allowing for the rapid progress of the incorporation movement since 1922, we believe that no exaggeration is involved in the statement that more than four-fifths of American business enterprise is now carried on by corporations. The advantages which American business corporations enjoy are: (1) Autonomy, which includes the right to sue or to be sued in the corporate name, the right to own and control property and the right to enter into legally binding contracts; (2) Continuity of existence going to the point, under the laws of twenty-three of the states, including Delaware, of perpetual life; (3) Limited liability of shareholders; (4) Flexibility of management; (5) Easy transfer of shares of stock and through them of ownership and control; (6) Elasticity of capital; (7) Release of shareholders and other beneficiaries from the responsibilities of management. To these the liberalization of corporation laws has added in many states: (8) Moderate fees for incorporation; (9) All-embracing or blanket charters under which almost any conceivable development of the original corporate purpose becomes possible; (10) Opportunity afforded ambitious business men to command the capital of minority investors without surrendering control over the business."

HORACE L. WILGUS,

Professor of Law, University of Michigan.

CORPORATIONS, Legal. Characteristics. In general the legal status of a cor-

poration is that of a *person*, with a name in which to do business, own or convey property, sue and be sued. It is normally managed by a board of trustees or directors, and officers, such as president, secretary, treasurer, etc. Its powers are those given at its creation. Its existence continues notwithstanding the death, withdrawal or insolvency of its members, or the transfer of shares, if it has a capital stock divided into shares. Its rights and obligations are its own, and not those of its members. Its creditors must look to it and to its property alone for payment, and not to its members, unless they have not paid for shares, or have wrongfully appropriated its property.

Classes.—Corporations are: *Aggregate*, created with a capacity to have more than one member at a time; or *Sole*, with capacity to have only one member at a time. Reduction to one member does not make an aggregate a sole corporation. Either may be: *Ecclesiastical* composed of ecclesiastical persons, for ecclesiastical purposes, and subject to ecclesiastical jurisdiction; or *Lay*, for temporal purposes, as "maior or communaltie, baylives and burgesses," and other business, social and literary purposes. In the United States, where there is no established church, church organizations, when incorporated, are *Religious Corporations*, and really *lay* corporations to manage the church business, without, and subject to no, ecclesiastical jurisdiction, except under the agreement of membership. Lay corporations are *Eleemosynary* (or charitable)—for the distribution of the alms of the donor or founder, as in the case of hospitals, colleges, etc.; and *Civil*,—for other purposes.

Civil corporations are: *Public*,—for governmental purposes, as the State, municipal corporations, etc.; *Quasi-public* (more properly, Public Service corporations),—for private gain but also to perform some public function as railroad, telegraph, etc., companies; and *Private*,—for advancing the interests of individuals in their private capacities. They are "not-for-profit,"—i.e., for the benefit of other than the members, as colleges, etc.; and for "profit,"—either pecuniary or otherwise. These are *non-stock*,—i.e., without capital stock and for some benefit other than pecuniary, as a literary society, or college fraternity; and *stock* (or moneyed),—for pecuniary profit by way of dividends on a *capital stock*. These classes are not mutually exclusive,—some corporations are within two or more of them.

In England, *lay* corporations are: *Trading* and *Non-trading*. They may be "chartered," by the king; or "Statutory," formed under acts of Parliament. These are usually called *companies*. The Non-trading are *Municipal*, for local government, or *Eleemosynary*, for charitable and benevolent purposes. Companies under the Companies Acts may be *limited by shares*, *limited by guarantee* and *unlimited*, according to the liability of the members. Other associations, resembling corporations, but without full corporate powers, or a "personal status," separate from the members exist both in England and the United States. They are: *public*, as counties, townships, parishes, school districts, etc.; territorial units for governmental purposes, or institutions, such as asylums, penitentiaries, State universities, etc., controlled by boards, with quasi-corporate powers; or *private*, such

CORPORATIONS, LEGAL

as miners' federations, labor unions, etc., stock exchanges, boards of trade, partnerships, syndicates, cost-book mining companies, joint-stock companies, trusts and partnership associations limited.

Joint stock companies are similar to corporations, but unless excluded by contract or statute, there is an unlimited individual liability of the members for the acts of the managers. The capital stock is usually divided into transferable shares, represented by certificates, and an owner is not an agent of the company unless he is so appointed. Recently "Trusts" have been organized for business purposes, with the legal title and power of managing the property vested in trustees, subject to the trust deed, the beneficial interest being represented by transferable trust certificates. In the absence of notice and agreement to the contrary the trustee is liable to third parties as an owner, and to the beneficiary for breach of trust. Partnership Associations, Limited, are created under statutes of Pennsylvania, Ohio, Michigan, etc., with powers very like corporations, with a capital stock, transferable shares and limited liability of members; the property is held and conveyed, and suits, by or against, are in the association name; they are not corporations for suits in the Federal courts, as a citizen of the creating State, without alleging and proving that no member is a co-citizen of the other party. The New York joint stock companies and some of the English insurance companies are similar.

Continental Systems.—Corporations are "Juristic Persons" in the Continental law, following the Roman. However, associations similar to those noted above exist. They are provided for in the Civil and Commercial codes. The general term is "Associations" (*Societas, Genossenschaft*), which includes both. Juristic persons are *Public*, as the state itself (*Fiscus*); *Charitable* (*Stiftung* or *Foundation*), the property, rather than its owners or managers, being personified. There are *Trading*, or *Non-trading* partnerships, syndicates, joint adventures, for profit, and associations for a common enterprise not for profit. The members are co-owners, but not partners. The *Trading* or *Mercantile* (provided for in the Commercial codes) are: *Société en nom Collectif* (*offene Handelsgesellschaft*), equivalent to our general partnership, but considered a juristic person in the Italian and Japanese law, so that death or withdrawal of a member does not dissolve, as it does in English, French or German law. *Société en Commandite* (*Kommanditgesellschaft*), with members with limited, and others, usually the managers, with unlimited, liability, corresponding to the English and American special or limited partnerships. *Société Anonyme* (*Aktiengesellschaft*), or joint stock corporation with transferable shares, limited liability of members, and managed by directors elected by shareholders. *Société commandite par actions* (*Kommanditgesellschaft auf Aktien*), a combination partnership and corporation, with shares, shareholders with limited liability, and managing partners with unlimited liability.

Tests of Corporate Existence.—The line of demarcation between an incorporated and an unincorporated body is not sharply defined. There is no universally accepted mark of a "juristic person," which excludes associations

not such. The American courts have suggested these tests in the creating State: (1) There can be no valid corporation without legislative authority; (2) when the legislative intent is clear, that will control in the creating State; (3) when this is not clear, resort must be had to *powers conferred*, and which, in order to make a corporation, must merge and vest the rights and liabilities of the individuals into one distinct, artificial existence. The courts of other States, however, will come to their own conclusions, from the powers conferred, and will not be bound by the legislative or judicial declarations of the creating State.

Creation of Corporations.—Coke said the essentials are: Lawful authority; persons to be incorporated; name; place; apt words. *Lawful authority* may be either by common law; act of Parliament; king's charter; prescription; to which may be added, implication and consolidation. By the common law, kings, bishops, parsons, vicars, deans, governors and officers generally are held to be corporations sole, "by the universal assent of the people from remote ages," and from necessity in order that they may carry out their official functions. For the same reason, the English "Parliament," the "United States" and the separate States, are held to be corporations aggregate, but the "British Empire," the "United Kingdom" and the "Church of England," are not. The king is the state. Australia, however, is considered a corporation sole. By legislative act—in 1523 Parliament incorporated the "Colledge of Physicians," and the king "in Parliament" has always claimed the power to erect corporations, as well as "without" Parliament. Like power inheres in the United States Congress, and in the State legislature, without express constitutional provision, and may be exercised by *special* or *general* act, if constitutions do not forbid. The colonial and State legislatures, in our early history, acted by *special* acts only. The Roman legislature acted either way. In 1597 a general law was passed for the incorporation of hospitals in England, and from 1844 to the present, various "Companies Acts" have been passed for the incorporation of companies by simple acts of registration. Public service corporations are usually provided for by special acts, embodying however various "general clauses," and monopoly or eminent-domain power, for jurisdiction contrary to the common law can be conferred only by Parliament, if to be exercised within the United Kingdom. On the continent, corporations are formed under the general provisions of the civil and commercial codes, but the legislatures of the several States may act otherwise. In 1778 Protestant churches were allowed freely to incorporate in South Carolina. In 1784 churches were incorporated in New York under general laws; in Delaware in 1787; in Pennsylvania in 1791; canal companies in North Carolina in 1795. In 1808 Massachusetts regulated manufacturing companies by general law, and in 1811 New York by general law, provided for their incorporation. In 1838 the Florida constitution directed the legislature to "pass a general law for the incorporation of all churches," and forbade their creation by special act. In 1845 Louisiana made a similar provision for all corporations "except for political or municipal purposes." New York (1846) made similar provisions, while

Ohio (1851) said "The general assembly shall pass no special act conferring corporate powers. Corporations may be formed under general laws; but all such laws may from time to time be altered or repealed." One or the other of these provisions now exists in nearly all the State constitutions, put there to secure equality of privilege, uniformity of powers and to prevent fraud, corruption and loss of time, incident to special legislation. There is no such limitation in the Federal Constitution, so Congress may act either by special or general act. In the manufacturing act of 1808, Massachusetts reserved the right to amend or repeal it. After the decision of the Dartmouth College Case in 1819, holding that an accepted corporate charter constituted a contract, the obligation of which could not be impaired by subsequent State legislation, State constitutions and incorporation laws usually provide that corporation charters shall be subject to repeal or amendment. The inhibition in the United States Constitution, against impairing the obligation of contracts, is on the States only. The United States government is one of express powers, and such as are necessarily implied therefrom, and so Congress (except in the Territories and District of Columbia, where it has a general legislative power), can create corporations only to carry out some of these express or implied powers. King's charter—"Anciently, a gild, either religious or secular could not legally be set up without the King's license," and in 1179 many "adulterine gilds" were amerced by Henry II. Bracton (c. 1260) said it was the exclusive prerogative of the king to grant franchises. However, as late as 1523, the Pope incorporated religious bodies in England. The bishops of Durham (a county Palatine) claiming *jura regalia* from the Conquest, incorporated the "Barkers and Tanners" at Gateshead, and granted charters to the city in 1565, 1602 and 1780. In 1376 it was held that only by the king could new corporations be created, though he could license another, as the chancellor of Oxford University, to create corporations to operate in Oxford. The Tudor sovereigns incorporated many "rotten boroughs," for political reasons. Henry VII granted charters to John and Sebastian Cabot in 1496, 1498 and from then to Victoria many great trading and colonizing companies have been incorporated by the English sovereigns.

In the United States, in colonial times, the king chartered corporations, e.g., William and Mary College (1693). Governor Andros of New York (1675, fisheries), William Penn (1682, trading), and Lord Baltimore, exercised such authority, but since the American Revolution the power is vested exclusively in the legislature, and not in the chief executive. Prescription—A body which has claimed and exercised unquestioned, corporate powers so long as to raise a presumption that a charter existed, but lost by the lapse and accidents of time, is said to exist by prescription, which is sufficient until the contrary is proved. Implication—Coke says "of ancient times the inhabitants or burgesses of a ville or burg were incorporated when the king granted to them to have a merchant gild." The king's charter to the "men of Dale and their successors," or an act of Parliament granting an estate in fee to the "Conservators of the river Tone, and their

successors" made them a corporation. Consolidation—this is now only by express legislative authority whereby two or more corporations unite to form a third, although in 1377 it was said one corporation could be so united to another as to succeed to its rights.

Persons to be incorporated—Coke says these may be either natural or artificial, but where the statute says "Three or more persons may incorporate," natural persons only are meant; however, in most of the States statutes authorize the consolidation, merger or amalgamation of two or more corporations into another, or the holding of shares in another. Sometimes incorporators are required to be citizens or inhabitants of the State, but not usually. A person incapable of contracting probably cannot be an incorporator, but incompetent persons may succeed to the ownership of shares. In the Roman and Continental law, a "bunch of property,"—a "foundation," or an "inheritance" might be incorporated, but in the English and American law it seems persons only can be incorporated, although possibly an "image of an Indian God" may be, under the English law. Persons become members only by consent, in complying with the charter and by-laws, in non-stock corporations; but by the ownership of shares in stock corporations, either by original subscription, purchase from a former owner, or by operation of law. Subscriptions may be either (1) to commissioners appointed to open books for that purpose; (2) in the incorporation paper, under general laws; (3) on a preliminary subscription paper; (4) agreement with a promoter; (5) contract with the corporation after it is formed; (6) underwriting; (7) application, allotment and notice. (1) and (2) are statutory and effective at once by force of the statute if it is followed. In (3) the corporation is not yet in existence, and if the paper reads: "We the undersigned hereby subscribe the shares set opposite our names," there are four theories in the American courts: (a) A mere offer to the future corporation, revocable by withdrawal, death or insolvency, any time before the corporation comes into existence and accepts; (b) A binding contract as soon as all the stock agreed upon is subscribed, the mutual subscriptions being considerations for one another, and since the group of subscribers is the same after, as before, incorporation, they then can enforce it in the corporation name. This accords with the intention and purpose of the parties. Only a few courts so hold however, the majority following rule (a); (c) Only an offer to the future corporation, but a contract among the subscribers, as soon as the subscription is complete. This recognizes the right of revocation as to the corporation, but not as to the subscribers. The result is not clear; (d) A binding agreement if, before incorporation, the subscribers have relied on the subscriptions to pay for property for the future corporation, and they cannot be placed in statu quo. (4) Subscriptions to promoters, before incorporation, are generally held to be enforceable by the corporation, when it comes into existence against either the subscriber, or the trustee; In (5) there is no difficulty about parties or consideration, and the subscription may be either oral or in writing; (6) An underwriter agrees to take the stock not subscribed by the public, for a commission, or at a discount from the price

to the public. The purpose is to guarantee the taking of the stock within a specified time; (7) Application, allotment and notice is the English method, where application is made to the promoters, who allot part or all the shares applied for, the contract being completed when the notice of allotment is dispatched. The effect of a completed subscription contract is to make the subscriber a member, whether or not he has paid, received a certificate or been registered as owner. He impliedly agrees to pay, upon call, the amount stated.

Name.—The early authorities said a name is of the very essence of the corporate institution, the knot of their combination without which corporate acts could not be performed. It is usually given by charter, but may be acquired by user. General laws require the name to be stated in the incorporation paper, and it must not be the same as another in the same jurisdiction. It may be protected as a trade mark, and its unfair use may be enjoined. A change of name does not change the identity of the corporation.

Place.—An old authority says: "There must be a place certain where to fix and bottom the corporation," for "without a place no incorporation can be made." General laws require the location of the "principal office," or "place of business" to be stated in the incorporation paper. Places within and without the incorporating state may be stated.

Proper words.—"But not restrained to any certain and legal and prescript form of words." Any, indicating an intention to incorporate, as "incorporate," "found," "erect," "create," "form," or others, will do.

Incorporation.—Acceptance of all (not part of) the terms offered by the lawful authority by the persons to whom made is essential. Promoters usually have the papers prepared, and secure the acceptance by the persons to be incorporated; they stand in a fiduciary relation both toward such persons, and the corporation, if formed, and are liable for unfair dealing, to both. In a special act, or a charter from the king, the terms, conditions and forms of organization are set forth, and may be accepted formally by resolution, or informally by acting under them. A contract then results between the corporation and the state, constitutionally exempt from subsequent amendment or repeal, unless such right is reserved.

Charter.—The document containing the grants is called the charter. If a special act, after acceptance it is not only a contract, but also a law of that state, which every citizen thereof is bound to know. When the act is general, then the details of any proposed corporation must be set out in an "Incorporation Paper" (usually prepared by the promoters), often called Certificate of Incorporation, Articles of Association, Memorandum of Association, etc. The general law usually requires the purposes, name, place, capital stock, amount subscribed, number of shares, names of incorporators or subscribers, to be stated in this incorporation paper, which must be signed, and acknowledged in a specified way by a certain number of incorporators, and then filed, recorded or registered in designated public offices. Other provisions as to organization, powers, voting, meetings, transfers of shares, reports, amendments, dissolution and winding up are

usually found in the general laws. These and the incorporation paper, executed as required, become the charter, and have the effect both of a law and a contract, as under a special act.

Compliance with Conditions.—Substantial compliance with the conditions precedent of the general law makes a *de jure* corporation, i.e., one invulnerable against the direct attack by the State. What are conditions precedent and what conditions subsequent are difficult to determine. Are the things to be done by the incorporators, or by the corporation? If the former, they are conditions precedent; if the latter, subsequent. In most States, a certain number of incorporators, written articles stating everything specified, executed in the precise way indicated, and filed as directed, are conditions precedent to *de jure* corporate existence.

De Facto Corporations.—In the United States, failure in some of these particulars does not make the effort abortive entirely. A good faith effort to organize under a valid law, colorable compliance therewith and corporate user,—although some condition has not been complied with,—results in a corporation *de facto*, valid as to all the world except the state in a direct attack for non-compliance with such condition. In a majority of the States it acquires a corporate status, and the members escape individual liability, as in a *de jure* corporation. Some deny this, in eminent domain proceedings by it, or to enforce preliminary subscriptions, or in suits against the members by persons not estopped by dealing with it as a corporation. *De facto* existence is not recognized in England or on the Continent.

Some courts go further and say that whenever a group of persons hold themselves out as a corporation, and thereby induce others to deal with them as such, it and they are estopped to deny the corporate existence, if it would be inequitable to do so. Some say estoppel arises only on matter of fact and not of law; others that there is estoppel only when there is *de facto* existence; and others deny the doctrine entirely.

Commencement of Corporate Existence.—Some statutes read "upon filing the incorporation paper the corporation shall be deemed to be in existence," before stock is subscribed or organization effected. They require the incorporators *after* filing the incorporation paper to take subscriptions, and when the requisite amount is subscribed to call a meeting of the subscribers to organize. Only an inchoate existence seems possible until there are stockholders and organization. The weight of authority so holds, but there is authority to the contrary.

Where to Incorporate.—Arizona, Delaware, District of Columbia, Maine, New Jersey (formerly), Porto Rico, South Dakota and West Virginia have more liberal incorporation laws, and lower fees, than many other States. Business men dislike divulging business secrets, making reports and being hampered in their operations, and so prefer incorporating in the "liberal States." To answer "where," various matters are to be considered, requiring careful attention and comparison by a competent attorney.

Corporate Rights.—"By incorporation it acquires *jus personæ*, and is capable of all civil rights of having and doing." So run the old authorities, and so was the Roman law. "No

freeman ought to be disseized," "No person shall be deprived of life, liberty or property," and "No State shall deny to any person the equal protection of the law," all include corporations; and generally the word person in statutes includes corporations, if the subject matter permits.

Of course a corporation has no body to be assaulted, beaten, imprisoned, hung or electrocuted, although old cases discussed the situation when it lost its head by the death or imprisonment of the dean of a chapter. It cannot "eat, drink or be merry," marry, have children, heirs, brothers or sisters, although "to-morrow it may die." It has no sex, race or color, but whether it is *it* or *they* has been discussed. It may have a good will, good or bad reputation and be slandered, libeled or maliciously prosecuted. It may be a "respectable and responsible person," but not a "colored person," or a "rogue or vagabond." In England and Germany it may be an alien enemy if incorporated, domiciled or controlled by agents, in the hostile state. The inferior courts of the United States have held otherwise if only incorporated in the hostile state.

In the United States a corporation is a citizen of the incorporating State, regardless of the citizenship, domicile or residence of its members, for suits in the Federal courts, and an inhabitant of the district in which it has its principal place of business. It can do business and have agents in other States, and sue and be sued there.

On the other hand, it is not a citizen of the incorporating State, within the meaning of the clause "the citizens of each State shall be entitled to all the privileges and immunities of citizens in the several States." Nor can it, nor its officers for it, refuse to produce its books and papers in evidence, because they would incriminate it. It has, however, whatever other rights are given it by its charter. And in general, a corporation has the same rights to sue either at law or in equity to protect or vindicate its rights as a natural person has.

Corporate Liabilities.—Corporations are subject to the general duties and obligations imposed upon other persons by the law, and are liable for breaches thereof. In the Roman law, Ulpian (*ad edictum*, 198-217 A.D.) said: "just as the praetor allowed an action on behalf of a municipality, he thought the edict should allow actions against one."

Torts.—Corporations are now held liable for torts both in England and America. Such liability was of slow growth due to the "artificial personality" theory, current in the Middle Ages. In 1234 Gregory IX authorized the excommunication of ecclesiastical corporations, but in 1245 Innocent IV forbade such "as the *innocent* may . . . be caught by a sentence of this kind." In 1348, in England, "The corporation is invisible, incorporeal, . . . Trespass does not lie against it, for *capias* nor *exigent*, lies not against a commonality," and in 1356 "Nor can they commit treason, or be outlawed or excommunicated, for they have no souls." This was frequently repeated (Coke 1600; Blackstone 1765) until down into the 19th century and corporations were thought not to be liable for torts or crimes of misfeasance. However, they were held in England for forcible disseizin (1357), and trespass (1371, 1430,

1454); negligence (Massachusetts 1810); conversion (England 1812); nuisance (Pennsylvania 1818); trespass to land (Delaware 1839); assault and battery (Florida 1842); deceit (Ohio 1846); false imprisonment (England 1851); malicious prosecution (Connecticut 1853); but denied in England until 1890 or 1904; libel (England and United States 1858); but only since 1880 for slander; exemplary damages (Illinois 1858); and tort in an *ultra vires* transaction (United States 1858).

Crimes.—Corporations were punished very early for delinquencies. The liberties of London were seized in 1245, for a false judgment by its magistrates, in 1264, for joining the barons against the king, in 1284, because the mayor, being bribed, connived at the bakers making their penny loaves six ounces too light, and many others, to the *quo warranto* in 1683, for extortion in tolls and the publication of a seditious libel. In 1811 a corporation was indicted for not repairing a bridge in England, and in 1812 in Massachusetts; in 1846, in England for disobeying a court's order, and obstructing a highway, followed by New Jersey in 1852; in 1876 for criminal libel in Missouri; in 1879 for Sabbath-breaking in West Virginia; in 1892 for keeping a disorderly house in New Jersey; in 1900 for criminal negligence, in not maintaining a bridge, causing death and equivalent to manslaughter by Canada Supreme Court. The United States courts refuse to go so far. Corporations, however, are generally held criminally liable for violations of pure food, anti-rebate, anti-trust and revenue laws, as well as for public nuisances. They are not yet held liable for higher felonies,—the requisite criminal intent supposed to be impossible and the punishments provided inapplicable.

Powers.—In England corporations chartered by the king have a *general capacity* to do anything not forbidden, while one created by an act of Parliament has only a *special capacity* to do what is expressed,—"only that and nothing more." Yet both have the incidental power of succession, to contract, grant, sue in its name, purchase property, have a seal and make by-laws. The doctrine of special capacities has obtained in the United States from the beginning, and for all corporations. This has led to the doctrine of *ultra vires*, beginning in 1804 in the United States, and in 1846 in England, based on four principles: (1) a corporation has no powers except those granted by its charter; (2) whoever deals with it must know these; (3) stockholders should not be subjected to risks not contemplated; and (4) the state is interested that the powers shall not be exceeded. An entirely executed contract will not be disturbed at the suit of either party; so, too, a wholly executory contract will not be enforced, or damages allowed for its breach by either party. In England, in many States, and by the Federal courts, an *ultra vires* act is legally void, because of incapacity of the corporation; in many other States, void because illegal as against public policy; but in New York and others valid and enforceable whenever it would be inequitable not to do so. When such contract is executed by one party but not by the other, the decisions divide: those holding it is void will allow no suit on the contract, but permit recovery in quasi contract or tort for benefits conferred if unjust to refuse; while

the New York courts would then permit recovery on the contract. If the public is injuriously affected by the *ultra vires* act, the State may dissolve the corporation in *quo warranto* proceedings. In the United States a business corporation may borrow money and give a note, secured by mortgage upon its property. In England the power is not so broad. There is no implied power to form a partnership, or become a guarantor or surety, for the accommodation of another. It may acquire its own shares to secure payment of a debt not otherwise collectible, but not for speculative purposes, to discriminate among its own shareholders, or defraud creditors. A corporation may acquire the shares of other corporations, but not for the purpose of controlling them. Investment, insurance and charitable corporations in some cases are held to have an implied power to invest in the shares of other companies. Many States by statute permit one corporation to hold stock in another. A corporation may now act as trustee, although the old cases said it had no conscience to be coerced by the chancellor. Statutes now generally allow the incorporation of trust companies with power to act as guardians, executors or administrators.

Landholding.—At common law, a corporation could acquire land as an individual, but this deprived the feudal overlord of his feudal relief, wardship and marriage fees, for corporations did not die, or have children. So in 1217, a gift to a religious house "is to be utterly void and that land is to accrue to the lord of that fee," if he enters within a year, or the next higher lord within six months thereafter, and so on to the king. When the Franciscan friars came to England under a vow of absolute poverty, *dominion* was sinful. Their need of food and shelter was supplied by a benefactor conveying his property to another for their use (*ad oeps*), as Richard le Mulines did at Oxford in 1225. The clerics caught the idea, and *uses*, enforced by the chancellor, enabled the corporations practically to evade the mortmain acts of 1217 and 1279. *Uses* were devisable but legal estates were not. So in 1391, another mortmain act, extending to lay corporations as well as ecclesiastical, and including *uses* was passed. In 1535 the Statute of Uses carried the legal estate to the holder of the use and made it a legal estate. In 1541 the first statute of wills enabled a man to devise land to any one. This seemed to repeal the mortmain statutes, if the land was devised to a corporation, so in 1543 the wills act was amended allowing devises to any one, *except corporations*. Thereafter the mortmain laws which still exist in England prevent a corporation from taking or holding land either by deed or will, unless expressly authorized by its charter.

Mortmain statutes do not exist in the United States, and statutes of wills do not generally forbid devises to corporations. However, under the doctrine of special capacity, a corporation has power to acquire only such land as is reasonably necessary for its purposes. More is held *ultra vires*. What is the effect? Under the mortmain policy the overlord could escheat it to himself, but neither the grantor, his heirs, nor the grantee corporation could repudiate the executed grant. There is no overlord here—but the State may bring *quo warranto* proceed-

ings against the offending corporation for its *ultra vires* act,—yet the title remains in the corporation and the land continues assets of the dissolved corporation by the weight of authority. Some cases hold otherwise. A limitation in a statute of wills against devising has a different effect from a limitation in the corporate charter to take and hold land. A devise contrary to the statute is void, passes no title, the heirs inherit, and the corporation gets nothing. If there is no limit on the power to devise, but only in the corporation's power to take or hold, a devise to it will be good,—but the State may dissolve the corporation for taking or holding. Such is the weight of authority, but there are several decisions to the contrary. A corporation may take an estate in fee, for life, for years, or at will, in common, remainder or reversion, but not dower, curtesy or joint tenancy.

Corporate Funds.—All the title, legal and equitable, belongs to the corporation, and not to the members, in equity, or as tenants in common, and this is true if the membership is reduced to one person. He does not own and cannot replevin the property. A conveyance by persons of their own property to the corporation for all of its stock is a real conveyance subject to a stamp tax (if there is one), and afterward the property can be taxed to the corporation and the shares to their owners. A member has an equitable right to have the funds applied only to the corporate purposes. In business corporations, the funds are represented by a capital stock, divided into shares; the authority for this, or to increase or decrease the same, must come from the State. The amount is stated in the incorporation paper; it is raised by subscription, to be paid as called for; it is the basis of corporation credit. If the net property of the corporation exceeds this capital stock, there is a surplus; if less, a deficit. The market value of all the shares may be more or less than either the property or capital stock.

Shares are generally required to have a *par* value,—\$10 or \$100,—but in New York, Delaware and Maryland may, by statute, be created without *par* value. Shares may be created with a preference as to dividends at incorporation, but afterward only by unanimous consent or statutory authority. In the absence of statutory inhibition, shares may be issued at a discount, valid between the corporation and the subscriber, but not as against the creditor who has relied upon the *par* value of the outstanding stock; if he cannot get paid otherwise he may compel the balance of the *par* value to be paid. New York holds otherwise. Even if the statute says "all fictitious issue of stock is void," the subscription at a discount is not void, the subscriber becomes a shareholder,—but he can be compelled to pay the "discount" for the protection of innocent creditors. Stock may be issued for such property as the corporation needs at a fair valuation, determined by the directors, and if in good faith and with reasonable judgment it will not be disturbed; excessive over-valuation is evidence of fraud, unless satisfactorily explained; a court of equity may require, for the protection of creditors, the difference between the reasonable value and that at which it was taken to be made good. Stock may be issued for patents, trade-marks, copyrights, formulas, good will and services, if

reasonably valued, in most States, but not in all. New York allows the payment for construction work at the actual value of stock without reference to par value, and generally when a corporation is in failing circumstances, in a good faith effort to resuscitate it, shares may be issued as a bonus to "sweeten bonds" without liability to subsequent creditors.

In 26 States there are "blue sky laws" (q.v.), forbidding corporations or dealers to offer corporate securities,—stock or bonds,—for sale as a continuous transaction, without first reporting to and securing a license from the State securities commission. In many States similar provisions exist as to public service corporations, which are required to get authority from public service commissions.

Corporate Action.—Since a corporation is one person made up of other persons, an organization of some kind is necessary in order that "they" may manage "it,"—for it can act only through agents or organs provided in its constitution. These are duly assembled meetings of the members, or directors, officers, agents, servants,—the last two not being parts of the organization. To be valid, a meeting must be called by proper authority, notified as required, and attended by a quorum. These usually are regulated by by-laws. If not, notice must be personal,—and all notified. At common law, a quorum of members,—being a fluctuating body,—consists of those who come, though only one or two; but of directors,—being a fixed body,—a majority is required. These should be fixed by by-laws.

Voting may be by show of hands, polling, viva voce or ballot, and, at common law, was by persons and not by shares, although now, in stockholders' meeting, usually by shares; in directors' meeting not. A majority vote of the quorum controls. Voting by proxy is now usual among shareholders, but should be authorized by statute, charter or by-law provision. Directors cannot, unless expressly authorized, vote by proxy. Some States have authorized shareholders to cumulate their votes for directors.

Seal.—The old authorities said a corporation "acts and speaks only by its common seal." This was the "visible sign of the invisible body," by which its will was made known, and the only authentic evidence of it. Exceptions allowed were in trivial matters, as driving out trespassing cattle; doing what the corporation was appointed to do; buying and using goods. A seal according to Coke is "an impression on wax," and this "magic of the wafer" yet exists in England, except as to corporations under Companies Acts (1908), which may contract in writing, by parole and without a seal wherever an individual may do so. Such has been the general rule in the United States since 1813 and 1827.

Members.—Their rights are Collective—(1) to elect directors, and sometimes officers; (2) amend the charter; (3) control the issue, increase and decrease of stock; (4) make and amend by-laws; (5) investigate management; (6) check *ultra vires* acts; (7) admit members; (8) remove members or officers for just cause; (9) dissolve the corporation,—all to be done in duly notified meeting; and Individual—(1) to have notice of meetings; (2) vote; (3) inspect books; (4) enjoin changes in the enterprise; (5) sue in equity for corporate wrongs

on behalf of all, when directors wrongfully refuse; (6) have a certificate of stock, if any; (7) transfer same; (8) be registered as owner; participate in (9) profits, (10) issue of new stock and (11) in assets on dissolution.

Notice.—actual, necessary at common law must conform to statute, charter or by-law, and if meeting is special, must state the purpose. Rules, same for shareholders' and directors' meetings.

Voting.—at common law by *persons*, not by shares, unless authorized by statute, charter or by-law. Directors vote only as individuals, not by shares or proxy. Shareholders may vote by proxy, if statute, charter or by-law allows, and perhaps such right may now be implied from the usual custom. Proxies are revocable, unless coupled with an interest. Voting trusts among shareholders are allowed in some States, in others not. If a corporation has 20 members each having one share, 11 votes could control; if these 11 form a trust to cast their 11 votes as a unit, to be determined by a majority of the 11, i.e. 6,—then the corporation is, or may be, controlled by 6 votes, instead of a majority; which is contrary to public policy by one view, but not by the weight of authority if not for some illegal purpose. Some States by statute allow cumulative voting; that is, if a member has one vote for each of five directors, he may vote all five for one and no more, or three for one, and two for another, and possibly thereby secure representation on the board.

Inspect books.—at common law only when a controversy existed between shareholder and the corporation, or among shareholders. The right is now usually broader, based upon the idea of co-ownership, but is usually regulated by statute, charter or by-laws. *Enjoin ultra vires acts*, on the theory that a member has an equitable interest in having the corporate funds applied to the corporate purposes only, and there is no other adequate remedy.

Certificate.—not necessary, but the usual and convenient evidence of membership, and when the shareholder is entitled to, he can compel its issue, or treat refusal as a conversion and sue for damages. It is not negotiable and a bonafide purchaser does not take it discharged of previous equities, unless the owner is estopped.

Transfer.—usually by endorsement, and delivery of the certificate for the purpose of transferring title. After endorsement in blank, it will pass by delivery, but a thief, or one getting his title from the thief, cannot pass good title so as to divest the real owner, if he was not negligent some way. In England the transfer is usually by a separate instrument.

Registration.—by weight of American authority, is not necessary to give transferee title, both legal and equitable. Some hold only equitable title passes by delivery of certificate without registration, and a few that registration is necessary to pass any title. Usually registration is for the convenience of the corporation in keeping track of its membership, giving notices and paying dividends—and in the absence of notice, corporation is not liable for following the register in these particulars. The rightful owner may demand and compel registration, or sue for damages for refusal. Corporation may demand reasonable proof of shareholder's right. In England and on the Continent registration is

generally necessary to confer complete rights of membership.

Dividends.—are properly declared and paid only when there are profits or a surplus, but this may be from earnings or increase in value of property. Current obligations, interest and taxes should be paid first; sinking fund to meet outstanding funded securities when due, and depreciation, should be provided for, but are not legally required. When proper conditions exist, whether a dividend shall be declared and paid rests in the sound discretion of directors, and may be either *cash* or *stock*; if cash the money is paid out to shareholders; if stock the money is kept by the corporation, but the stock to an equal amount is issued to the shareholders, in which case there must be authority to increase the stock. A dividend is declared by resolution of directors, and when notified to shareholders, becomes irrevocable, and makes the shareholder a creditor of the corporation, for his part of the dividend, whether then due or not, and when the dividend fund is actually or constructively set aside, the shareholders then become not only creditors but the equitable owners of it. The owner of the stock at the time it is declared is the owner of the dividend, without reference to when the profits were earned, or time of payment, or name on the register, although the corporation will be protected if it pays the registered owner, without notice of the real owner. Of course the parties may stipulate as to who shall be entitled to the dividend, and when sold on the stock exchange its rules apply. Shares may have a preference in dividends if originally created as preferred and common. "Seven per cent. preferred" entitles the holder to receive 7 per cent before the common receives anything, but only out of profits; also, cumulative, i.e., to receive when profits are sufficient, what was unpaid up to 7 per cent for back years, although some courts hold this is not so unless expressly stated to be cumulative. By weight of authority, preferred shares are not entitled to participate in profits beyond their preference, but Pennsylvania holds that preference stock participates equally with the common after it has received the same as the preferred. Even if the preferred is guaranteed, it is entitled, not to interest, but to dividends out of profits only. Efforts to make preferred shareholders creditors, on equality with other creditors, in reference to the capital have failed,—and their stock is postponed to creditors' claims.

Participation.—proportionally, in issue of new stock, at its par value, whatever may be the market value, is a right incident to existing stock, of which the shareholder cannot be deprived without his consent. Participation in assets is considered below.

Directors.—Though elected by shareholders, or members, directors receive their authority from the State, and their judgment is not subject to control of members. They are clothed with the business powers only,—advisability of corporate action, selection of inferior officers and agents, application of funds, declaration and payment of dividends. These duties are fiduciary toward the corporation and shareholders and directors must act with reasonable skill and diligence,—that of any ordinarily prudent man in his own affairs according to some authorities—but being paid only in fees, ac-

cording to other authorities, only the ordinary care of a gratuitous bailee is required. To some extent they are general agents, mandatories and trustees, but, in good faith, by the weight of authority, they may deal with the corporation itself, though some authorities hold the corporations may object, if it acts promptly. Dealings between corporations having the same directors, or a majority of the same, are subject to similar rules. Slight evidence of unfairness or overreaching will enable the corporation to impeach the transaction.

Officers.—President, secretary, treasurer,—with the power incident to such officers in deliberative assemblies generally, and no others, without others are conferred expressly, or impliedly by "holding out,"—are customary. The secretary is usually made custodian of the corporate seal, and the president, general manager. For performing the official functions incident to their offices they are not entitled to pay, but for other service they are. There is no right of removal during term of office, by shareholders, unless statute, charter or by-law so provides. For gross misconduct, or fraud, a court of equity on proper application and showing may remove.

Creditors.—The corporation and its property only are liable to creditors; the members are not, unless they have not paid for their stock, or wrongfully received the corporate property, or by statute. The corporation has the same power, within its charter, to manage and control its property, without interference by creditors as would an individual, and as he may, so may the corporation, prefer creditors, by the weight of authority. Some States hold otherwise, and the present United States bankruptcy law now forbids preference made within four months of bankruptcy. Some permit the corporation to prefer its own officers as creditors, if there is no actual fraud. Perhaps the weight of authority is the other way however. Creditors of course may complain of the disposition of the corporate property for the purpose of defrauding them, and have all the ordinary rights at law and in equity, against the corporation, and its property, they would have against an individual, but in the case of a public service corporation its property cannot be taken on execution so as to prevent the performance of the public duties. Resort must then be had to the sequestration of earnings by receivership or otherwise.

It is often said that the corporate assets are a trust fund for the protection of creditors. Assets here include the corporate property, what is owing to it by others whether by members for unpaid stock or issued for over-valued property, or otherwise, or by others including claims for wrongs done to the corporation by the wrongful disposition or negligent dissipation of its funds. A receiver, in a court of equity, or a creditor by a creditor's bill, after an unsatisfied judgment against the corporation, can reach all the foregoing, so far as necessary to pay the creditors. This, however, is not a trust fund in the sense that the corporation has the legal, and the creditors have the equitable, title, before the court has taken possession of the property on behalf of creditors. Only such creditors as have relied upon the outstanding stock or property can complain. Creditors who become such *before* the unpaid stock was issued

Late Professor of Law, University of Michigan.

CORPORATIVE STATE, a system of government in which the population is grouped according to economic activity in more or less compulsory "corporations," syndicates, or guilds, which are represented in the government. First established in Fascist Italy, it has been an instrument of dictatorship, bringing economic activity under strict government control through the filling of key posts with faithful party members. In Italy in 1926, 13 syndicates were formed from employers and employees (separately) in agriculture, industry, commerce, banking, air and marine transport, and land transport and inland navigation; with one for arts and professions. They were consolidated in a National Council of Corporations in 1929 under a state minister. In 1934 their number was increased to 22, and their nominal political power was increased. In 1938 the Chamber of Deputies was abolished and replaced, as the lower house of the Italian Parliament, by the Chamber of Fasci and Corporations, consisting of 150 members of the National Council of the Fascist Party and 500 members of the National Council of Corporations.

Although the Italian corporative state was destroyed by World War II, variants of the system survived the war in Spain and Portugal. In the Spanish Parliament (the Cortes), as reorganized by Francisco Franco in 1942, roughly a third of the members are representatives of the national syndicates. In the Portuguese "New State" constituted in 1933 by Antonio de Oliveira Salazar, the Corporative Chamber sits concurrently with the National Assembly (Cortes Gerais) and has advisory powers.

CORPS, kôr, a body of persons, usually under common direction. The term may be applied to various divisions of troops; the *corps d'armée* is a military unit composed of from two to four divisions; the *corps de garde* is a body of men on guard, or the guardhouse.

In political usage, the term *corps législatif* was employed from 1857 to 1870 to designate the lower house of the French legislature. The *corps diplomatique* refers to a nation's entire body of diplomatic officials.

The word is also used in a less specialized sense as in *corps de ballet*, a ballet company. *Esprit de corps* is the spirit pervading a group of individuals dedicated to a common cause.

CORPSE, a dead body, in most common usage applied only to the human body. To the human corpse there can be no property rights, save in the rare case of disposition by regular will of one's body. Questions about disposition of a corpse are heard by an ecclesiastical court in England and by the civil courts in the United States and other countries where church and state are separate. Prior right to a dead body naturally goes to the nearest of kin, marriage ties ranking above those of blood. Burial expenses come under the general head of property rights in that they take precedence over any claims against deceased or his estate. Mutilation of the buried body, and body-snatching, are criminal offenses.

CORPULENCE is bodily bulk, particularly obesity (q.v.).

CORPUS CHRISTI, kôr'pûs krîs'tî, city, Texas; seat of Nueces County. It is situated

at an altitude of 40 feet on Corpus Christi Bay at the mouth of the Nueces River, 140 miles south of San Antonio, and is served by the Missouri Pacific, the Southern Pacific, and the Texas Mexican railways. The city has an airport with airline service; and steamship connections with gulf and ocean ports. The surrounding country produces cotton and oil. Corpus Christi has oil refineries, cotton gins and compresses, alkali plants, and a smelter, and produces cement, and corn and cellulose products. In volume of business handled, its port ranks third among the state's fourteen. The connection with the Gulf Intracoastal Waterway, serving more than 25 coastal cities, was completed in 1943. The city has a community center, city and county libraries, a county museum, hospitals, a naval air training station and several subsidiary fields.

The coast was explored by Alonzo de Piñeda in 1519; the city was first settled in 1839, and incorporated as a city in 1852. Its history included episodes of the Mexican War and the Civil War. Corpus Christi has a city-manager form of government, with mayor and commissioners. The water and gas systems are city owned. Pop. (1930) 27,789; (1940) 57,301; (1950) 108,287.

• **CORPUS CHRISTI**, Festival of, a feast instituted by the Roman Catholic Church in honor of the mystery of the Eucharist, observed on the first Thursday after Trinity Sunday. The feast is due to St. Juliana (1193-1258), prioress of Mont Cornillon, near Liège, Belgium. Her veneration for the Host led her to propose a special feast in its honor, and this was instituted as a diocesan feast by Robert de Thorete, bishop of Liège, in 1246, and first celebrated the following year. It was not extended to the whole church, however, until the archdeacon of that diocese, Jacques Pantaléon, became pope in 1261, as Urban IV. The latter published the bull *Transiturus*, Sept. 8, 1264, ordering the celebration of the feast throughout the church. But the pope's death a month later prevented its spread until the Council of Vienne (1311-1312), when Clement V published a decree incorporating that of Urban IV, after which it found general acceptance. At the request of Urban IV a remarkably beautiful office was written for the feast by St. Thomas Aquinas.

While the procession of the Host is not mentioned in either papal decree, it originated about 1275 and soon became the most distinctive feature of the feast; crowds of richly dressed nobles, magistrates, merchants, and guildsmen forming the procession in the cities. This feature is important in the early history of the drama for the miracle and mystery plays presented by members of the trade and craft guilds. At the Reformation, the Feast of Corpus Christi was one of the first holidays abolished by Luther. The procession, which may be held on the Thursday of the feast, is usually held in the United States on the Sunday following.

CORPUS CHRISTI COLLEGE, Cambridge University, England, sometimes called Benet College, was founded in 1352 by the united guilds of Corpus Christi and the Blessed Virgin, two fraternities which used to meet for prayers at Saint Benedict Church and Saint Mary's respectively. The endowments of the college were considerably increased by Archbishop Matthew

Parker, who also bequeathed to it his valuable collection of manuscripts. It has a fine collection of plate and the Lewis collection of printed books. Christopher Marlowe and John Fletcher were members of Corpus Christi.

CORPUS CHRISTI COLLEGE, Oxford University, England, a comparatively small college founded in 1516 by Richard Fox, bishop of Winchester and lord privy seal, under a license from Henry VIII. There are about 100 undergraduates. The college counts among its famous men Nicholas Udall, author of *Ralph Roister Doister*; Richard Hooker; John Keble, the hymnologist; and Thomas Arnold, the master of Rugby.

CORPUS DELICTI, kôr'pûs dê-lik'ti (literally "the body of the crime"), in Scottish law, those external marks, facts or circumstances which accompany a crime, and without the proof of which the crime is not supposed to be established. Thus the corpus delicti of homicide is establishing the fact that the person has died of violence, not merely that he has died. According to German law no crime can be established unless the corpus delicti is clearly present, and self-accusation or confession without this does not empower a court to convict.

CORPUS DOCTRINAE (Lat. "body of doctrine"), in German ecclesiastical history, the name given to each of several collections of theological writings promulgated by various German Protestant churches during the 16th century. Among the most important of these collections were the *Corpus Misnicum* or *Philippicum* (1559), enforced by the elector of Saxony, containing the Apostles', Nicene and Athanasian creeds, the Augsburg Confession and Melancthon's *Loci Communes*; the Pomeranian of 1561; that of Nurnberg of 1573; and the Hamburg (1560), Brunswick (1563), Pomeranian (1564), Prussian (1567), Brunswick-Wolfenbüttel (1569), Saxon (1570, called *Corpus Thuringicum*); and others of a Lutheran character. These were all superseded in 1580 by the *Formula Concordiae*.

CORPUS JURIS CANONICI, kôr'pûs jôô'ris kâ-nôn'i-si, the body of laws for government of the church enacted by popes, councils, and synods, or drawn from the writings of the fathers, and the whole approved and promulgated by the Holy See. The first compilation was that of Gratian, the Camaldolese monk, professor of theology in the University of Bologna, who about 1150 compiled the *Concordantia Discordantium Canonum*.

In the reign of Henry VIII the English Parliament ordered a revision of the *Corpus Juris Canonici* to make it conform to the new order of things brought about by the law of the king's supremacy in matters of religion; meanwhile the old system was to hold so far as might consist with the new order. But no revision has been made, and hence, with a few reserves, the *Corpus Juris Canonici* is law for the Church of England. See also CANON LAW.

CORPUS JURIS CIVILIS. See CIVIL LAW.

CORPUSCLE, in anatomy, a small, usually microscopic, body regarded by itself and defined

by some qualifying term. Examples are the blood corpuscles or blood cells (see BLOOD); the Malpighian corpuscles of the kidney and the spleen; the tactile corpuscles, also known as Meissner's and Wagner's corpuscles, found in certain papillae of the skin of the hand and foot; the taste corpuscles or taste buds; and the Pacinian corpuscle (q.v.).

CORPUSCULAR PHILOSOPHY, a name sometimes applied to the atomic philosophy taught by Leucippus and Democritus (qq.v.). According to their doctrine, matter is eternal, and everything in the universe, including the soul, is produced by a special arrangement and aggregation of minute, indivisible bodies or particles called atoms. These atoms are of various sizes and shapes and, in some forms of the theory, of different qualities. It is on these primary differences, combined with the endless varieties of position and figure, that distinctions between things are based. Change is only a rearrangement of atoms caused by their unceasing primary motions. This philosophy was elaborated and developed by Epicurus and other thinkers, and received its finest expression in the great poem of Lucretius, *De Rerum Natura*, q.v. (*On the Nature of Things*). It may be regarded as an ancient form of the modern atomic theory (q.v.), which, however, differs from it in being, not a philosophy of the universe, but merely a hypothesis concerning the physical constitution of matter, adopted in order to give convenient expression to scientific facts.

CORPUSCULAR or EMISSION THEORY OF LIGHT. See ELECTRON THEORY; LIGHT—*Nature of Light*.

CORREA DA SERRA, kōōr-rā'à thā sēr'rá, José Francisco, Portuguese statesman, scholar, and botanist: b. Serpa, Portugal, June 6, 1750; d. Caldas da Rainha, Sept. 11, 1823. He was educated in Rome and Naples, and in 1779 was among the founders of the Portuguese Academy of Sciences. To escape the Inquisition, he went to France in 1786, and there became closely associated with the naturalist Auguste Broussonet. From 1797 to 1802 he served as secretary at the Portuguese embassy in London, and in 1813 went to the United States, where he continued his scientific studies. Appointed minister plenipotentiary of Portugal in Washington in 1816, he served in this capacity until 1820, when he returned to Portugal and was elected a deputy to the Cortes. His principal published work is *Colecção de livros inéditos da história portuguesa* (4 vols., 1790–1816).

CORREA GARCAO, kōōr-rā'à gēr-soun', Pedro António Joaquim (academic name CORYNON ERIMANTHED), Portuguese poet: b. Lisbon, Portugal, April 29, 1724; d. there, Nov. 10, 1772. The son of an official in the Ministry of Foreign Affairs, he was educated at the University of Coimbra, where he studied law and received his degree in 1748. In 1756 he played a prominent part in the founding of the Arcádia Lusitana, or Arcádia Ulyssiponense, an academy designed to free Portuguese literature from artificiality. Imprisoned by the marquês de Pombal in 1771, he died on the day he was released. Correa Garção was primarily a lyric poet. Besides sonnets, he wrote a number of odes and epistles

modeled after those of Horace and two comedies in 11-syllable verse: *Theatro novo*, which appeared in 1766; and *Assemblea*, containing the celebrated *Cantata de Dido*.

CORREGGIO, kōr-rād'jō (real name ANTONIO ALLEGRI DA CORREGGIO), Italian painter: b. Correggio, Italy, 1494¹; d. there, March 5, 1534. Little is known of his early life and training, but his first important work, the *Madonna with Saints* painted in 1514–1515 for San Francesco in Correggio, reveals familiarity with the styles of Raphael, Michelangelo, and Leonardo da Vinci. These influences continue throughout his career, even though all evidence points to his having been active almost exclusively in Correggio and nearby Parma. His own style is in the grand manner initiated by these men but has a markedly personal flavor, soft and poetical in the treatment of light and color, joyous and exuberant in overall expressive character. His most impressive works are a series of mural decorations, beginning with the ceiling of a room painted in 1518–1519 in the Convent of San Paolo at Parma. Then follow the boldly original frescoes in the dome of San Giovanni Evangelista at Parma painted between 1520 and 1524. Here the ascending figure of Christ in the center is watched by the Apostles who form a ring around the edge of the dome. The sharply foreshortened figures of the Apostles seated on clouds filled with angels give a strong sense of upward movement into space. This idea is further elaborated in his most famous work, the fresco decoration of the dome of the Cathedral of Parma, painted between 1526 and 1530. In this larger painting the eye is carried up through two concentric rings of foreshortened figures. The lower ring features the standing figures of the Apostles looking up at the group in which the Virgin Mary ascends to heaven in the company of many saints and angels. The complex interweaving of the figures and the many outthrust arms and legs serve both to increase the sense of movement and to convey a quality of exultation appropriate to the theme. These paintings were far ahead of their time. They met with mixed reactions then and their greatest influence was felt in the next century in the work of baroque muralists in Rome. Of Correggio's many altarpieces in oil, some, such as the *Madonna of St. George* (Dresden), are in the current mannerist style; others, such as the *Madonna with St. Jerome* (Parma) and the *Adoration of the Shepherds* (Dresden) anticipate the 17th century in their treatment of light and space. At the end of his life Correggio devoted himself mainly to themes from classical mythology. In these works his soft modeling and frank sensuousness create an expressive quality that is highly individual, as may be seen in his *Jupiter and Io* (Vienna) and *Leda* (Berlin). Correggio's influence and reputation grew steadily in the later 16th and 17th centuries. He was the founder of the school of Parma and his influence spread beyond Parma and is reflected in the academic style initiated by the Carracci in Bologna and Rome as well as in the work of more baroque artists in Rome and outside of Italy.

Consult Moore, T. S., *Correggio* (New York 1911); Bodmer, H. D. A., *Correggio und die malerei der Emilia* (Vienna 1942).

¹ Some authorities give c.1489.

CORREGGIO, commune, Italy, situated in Emilia-Romagna, in the Province of Reggio nell'Emilia, 8 miles northeast of the city of Reggio nell'Emilia. It owes its fame to the painter Antonio Allegri, known by the surname Correggio, who was born here in 1494; his statue stands in the main square. In the 15th and 16th centuries the court of the Correggeschi, lords of the town, was a brilliant center of learning and the arts; among its guests were Emperor Charles V and the poets Lodovico Ariosto and Torquato Tasso. The 16th century palace of the lords now houses the municipal library and the historical archives. Establishments in the commune produce wine, sausages, and pharmaceuticals. Pop. (1951) 19,338.

CORREGIDOR, kō-rēg'i-dōr (Span. kōr-rē-hē-thōr'), island, Philippines, situated in Cavite Province, at the entrance to Manila Bay, 3.5 miles south of the southern tip of Bataan and 28 miles west-southwest of Manila, which it was fortified to defend. Of volcanic origin, the island is shaped like a polliwog, 1 to 3 miles wide and 5 miles long, with an area of 2.25 square miles. It rises to a high point of 649 feet near its western end. San José, a trading and fishing community, is the only village on the island.

Although Corregidor was strongly fortified by the Spaniards in the 18th century, by the time of the Spanish-American War its defenses had deteriorated to such an extent that it offered no resistance to Commodore (later Admiral) George Dewey's fleet as it steamed past the island into Manila Bay on May 1, 1898. Corregidor became a United States military station in 1900. Fort Mills was established on the island, and its defenses were gradually strengthened. An extensive network of tunnels was dug in Corregidor, and Forts Frank, Drum, and Hughes were erected on the neighboring islets of Carabao, El Fraile, and Caballo, respectively. During World War II, United States forces on Corregidor held out under steady Japanese attack for 27 days after the fall of Bataan. Finally, on May 6, 1942, Lieut. Gen. Jonathan M. Wainwright was forced to surrender. The island was recaptured by United States forces on Feb. 16-22, 1945, and passed to the sovereignty of the Republic of the Philippines in 1947.

CORRESPONDENCE SCHOOLS AND COURSES. Adult education by means of courses conducted by correspondence is widespread in the United States and other countries. The movement developed from the university extension movement, which began in England in 1868. Spreading to the United States, it was furthered by the Chautauqua Institution (q.v.) and by the establishment of special correspondence schools, such as the short-lived Correspondence University of Ithaca, N. Y., founded in 1883, and the well-known International Correspondence Schools of Scranton, Pa., which grew out of a course in coal mining first offered in 1891. In 1892 a correspondence department was established at the University of Chicago, and correspondence courses were gradually instituted in other colleges and universities, notably in the land-grant colleges after the passage of the Smith-Lever Agricultural Extension Act in 1914. In 1915 the National University Extension Association was formed, and in 1926 the National Home Study Council, a trade as-

sociation of leading private correspondence schools, was established. Correspondence courses have been widely used in the armed forces, notably through the Armed Forces Institute.

CORREZE, kō-rāz', department, France, in Limousin, in the Massif Central. Bordered on the northwest by Haute-Vienne, on the north by Creuse, on the east by Puy-de-Dôme and Cantal, on the south by Lot, and on the west by Dordogne, it has an area of 2,272 square miles. The department is watered by the Corrèze, Dordogne, and Vézère rivers, whose hydroelectric resources have been extensively developed. The soil is not very fertile except in the river valleys, but livestock, barley, wheat, rye, tobacco, vegetables, corn, fruit, and potatoes are raised. Slate is quarried, and there are textile mills, tanneries, and food-processing plants in the towns. Brive-la-Gaillarde is the largest town, and Tulle is the capital. Corrèze is divided into 3 arrondissements, 29 cantons, and 289 communes. Pop. (1946) 254,601.

CORRIB, Lough, lök kōr'ib, lake, Ireland, situated in Galway and Mayo counties, south of Lough Mask, with which it is connected by a partly subterranean channel. The lake is navigable, as is its outlet, the Corrib River, which flows from the southeastern end into Galway Bay. About 27 miles long and 1 to 10 miles wide, Lough Corrib has an area of approximately 71 square miles. It contains many islands, among them Inchagoill, which has the ruins of two ancient churches.

CORRIENTES, kōr-ryān'tās, the name of a province and a city in Argentina.

(1) The province, situated in Mesopotamia, has an area of 34,500 square miles. It is bounded on the west and north by the Paraná River, which separates it from the provinces of Santa Fe and Presidente Perón (formerly the Chaco) and from Paraguay; on the northeast by Misiones; on the east by the Uruguay River, which separates it from Brazil and Uruguay; and on the south by Entre Rios. Corrientes is well watered (in places, marshy), and the soil is fertile. Sugarcane, tobacco, cotton, wheat, corn, rice, fruit, nuts, and olives are grown extensively, and sheep, cattle, and horses are raised. Pop. (1947) 525,463; (est. 1951) 590,495.

(2) The city, which is the capital of the province, is situated on the Paraná River about 25 miles below its confluence with the Paraguay, and 480 miles north of Buenos Aires, with which it is connected by rail and air. It has an imposing capitol, a cathedral in the Renaissance style, several interesting churches (Las Mercedes has a Renaissance façade, and La Cruz, rebuilt in 1808, is a pilgrimage center), the Museo Colonial, Histórico y de Bellas Artes and an academy of arts. The city serves as the processing and shipping center for the surrounding rich agricultural region, and it has shipyards, textile mills, sawmills, and tanneries. Founded in 1588, it was the scene of a battle during the war with Paraguay in 1865. Pop. (1947) 56,425.

CORRIGAN, Michael Augustine, American Roman Catholic prelate: b. Newark, N. J., Aug. 13, 1839; d. New York, N. Y., May 5, 1902. After attending St. Mary's College, Wilmington, Del., for two years, he entered (1855) Mount

St. Mary's College, Emmitsburg, Md., from which he was graduated in 1859. In that year he was one of the first 12 seminarians to enter the American College in Rome. Ordained a priest in 1863, he remained in Rome for a year of graduate study, receiving his doctorate in 1864. Returning to the United States, he became professor of dogmatic theology and sacred scripture at Seton Hall Seminary, South Orange, N. J. From 1868 to 1876 he served as president of the institution. He became bishop of Newark in 1873. His tenure was marked by notable advances, particularly in the foundation of charitable institutions and the establishment of parochial schools. In 1880 he was made archbishop of Petra and coadjutor to John Cardinal McCloskey, archbishop of New York. On the death of the latter in 1885, he succeeded as archbishop, being installed in the following year. During the 17 years he headed the archdiocese, it became one of the largest in the world. Archbishop Corrigan was particularly concerned with the problems of new immigrants, with education, and with questions of canon law.

CORRODENTIA, kŏr-ô-dĕn'shĭ-ă, an order of primitive terrestrial insects having a single metamorphosis, modified biting mouth parts, either short or long antennae, compound eyes which are usually large and well separated, three or no ocelli, a small and necklike prothorax, slender legs with two or three segmented tarsi, and no abdominal cerci. The insects are either wingless or have two pairs of wings, with the hind pair smaller than the front ones and with simple venation.

The order includes the book lice, which are wingless, and the bark lice, which almost always have fully developed wings. Probably the most important species is the deathwatch (*Liposcelis divinatorius*), wingless and pale yellowish, which occurs in almost every building and sometimes becomes exceedingly numerous. It is able to make a slight ticking sound which can be heard in the stillness of the night. A close relative is *Atropus pulsatorium*, which has similar habits. The Corrodentia feed almost entirely on fungus, but they also eat starches. The winged forms are common on moist tree trunks.

CORROSION. The corrosion of metals is a form of chemical deterioration. The problem is continuous, since all metals and their alloys are subject to some degree of corrosion under certain conditions. The resistance of a metal to corrosive attack depends on the nature of the corrosion product formed. Some metals, such as chromium and aluminum, form an adherent, impervious coating that prevents further corrosion by acting as a barrier to the corrodent. The extent to which corrosion takes place and the rate at which it proceeds depend on the metal or alloy used, the combination of metals and alloys in contact with each other or with nonmetallic materials, and the corrosive medium present. Since corrosion is a chemical and electrochemical phenomenon, an increase in temperature usually accelerates it.

Corrosion of metals results in a tremendous loss of materials and money. Various estimates have placed the annual cost of corrosion in the United States alone at over \$5 billion. The problem is extremely complex, and vast amounts of time and energy are expended in research.

Types.—Corrosion reactions can be classified as direct atmosphere or chemical attack, or as electrochemical action. Examples of direct atmosphere or chemical attack are the oxidation of iron and steel at elevated temperatures, the oxidation of aluminum and magnesium, and the tarnishing of copper. Electrochemical attack, which requires that a liquid be present, involves a transfer of electrons in which some positively charged ions in the corroding solution lose electrical charges, which are acquired by the metal or alloy going into solution, or being corroded.

Galvanic corrosion may be defined as accelerated electrochemical corrosion produced when one metal is in electrical contact with another, more noble (more resistant) metal, both being in the same corroding medium or electrolyte. This type of corrosion usually results in a higher rate of solution of the less noble metal and in the protection of the more noble metal. Galvanic corrosion is usually characterized by severe local corrosion at the point of contact of the dissimilar metals, if that contact takes place in the electrolyte.

Stress corrosion is corrosion accelerated by internal stresses or externally applied stresses. Not only may differential stress produce corrosion, but corrosion from any cause may produce a weakening in a part which may crack under a stress that would not otherwise have affected it. Corrosion fatigue is a form of stress corrosion in which the stresses are fluctuating or cyclic in nature.

Pitting occurs when corrosion is localized. This is most serious in containers, which may become perforated in a short time. Moreover, the pits, when small in area or few in number, can easily be overlooked.

Dezincification is a type of corrosion in brass in which zinc atoms are dissolved from the solid solution in preference to copper atoms. It results in a surface deposit of copper over a porous and weakened base. In a broader sense, dezincification includes any similar selective leaching of one component from an alloy.

Erosion corrosion occurs in the presence of rapidly moving liquids and turbulence, and is increased by the presence of suspended solids. In this form of corrosion, a surface weakened or made porous by corrosion is quickly eroded. Pumps, valves, ship propellers, and agitators are examples of equipment subject to erosion corrosion.

Prevention and Protection.—There are many methods of combating corrosion. They involve either removing, if possible, the causes of corrosion, or protecting the material. Preventive treatments include annealing, which can remove stresses to avoid stress corrosion; and the addition of certain elements to produce corrosion-resistant alloys.

Surface treatments to protect the metal are varied. A more resistant metal, such as cadmium, zinc, nickel, or chromium, can be electroplated on a more corrodible metal. Coating by dipping in a molten metal such as zinc or tin is an extremely important method. In coating iron with zinc (galvanizing), not only is the iron protected by a rustproof metal, but advantage is taken of galvanic action. If a break in the coating occurs and the iron is exposed, the zinc and iron form a galvanic couple, and the zinc is oxidized, protecting the iron.

Cladding (covering with another metal by a

cold rolling process), metallizing (spraying with a molten metal), and applying metallic paints are other methods of protection. Processes for coating steel with other metals include sherardizing (zinc coat), calorizing or aluminizing (aluminum coat), chromizing (chromium coat), and Irligizing or silicizing (silicon coat). Non-metallic coating methods include painting, lacquering, plastic coating, porcelain enameling, and the application of greases.

Another means of protection consists in the artificial building up of an oxide film or the production of a protective film of some other composition. The anodizing of aluminum and the blue color on some razor blades are examples of artificial oxidizing for protection. Other protective films are made by chemical surface treatments or dips. Phosphate coatings are produced on steel, and magnesium alloys are given surface treatments to improve corrosion resistance.

In another type of protection, use is made of electrochemical principles. This method, cathodic protection, consists in applying an electric current, either externally or by galvanic coupling, to a specific metal surface in such a manner that the usual electrochemical corrosion reactions are slowed or counteracted. Currents can be applied by an external source of power or by means of sacrificial anodes. Sacrificial anodes, usually made of zinc, magnesium, aluminum, or alloys of these metals, reduce the rate of attack on the metal to which they are coupled. Buried near steel pipes and spaced at proper intervals, sacrificial anodes are used to protect underground pipelines, and they are also used in ship propeller shafts.

Consult Woldman, N. E., *Materials Engineering of Metal Products* (New York 1949); Gillett, H. W., *The Behavior of Engineering Metals* (New York 1951); Stoughton, Bradley, Butts, Allison, and Bounds, A. M., *Engineering Metallurgy*, 4th ed. (New York 1953).

ALVIN S. COHAN,
Editor, "Journal of Metals."

CORROSIVE SUBLIMATE, mercuric chloride (HgCl_2). Also known as bichloride of mercury and perchloride of mercury, it is prepared by heating mercuric sulphate with dry sodium chloride. The mercuric chloride sublimes as a white, transparent, crystalline mass with a specific gravity of about 5.42 and a molecular weight of 271.52. It is soluble in about 20 parts of cold water and very soluble in alcohol and ether. Since it precipitates albumen, white of egg is an antidote to its effects. It is very poisonous, and is used as a germicide and externally in certain skin diseases. It is also employed in chemical analysis, tanning, photography, and metallurgy.

CORROSIVES, in medicine, substances which corrode the part of the body to which they are applied. Among them are acetic acid, exsiccated or burnt alum, ammoniated mercury, zinc sulphate, mercuric oxide, and antimonie chloride.

CORRUGATED IRON, sheet iron formed with parallel ridges and furrows, so that the cross-section is a continuous waved line. Flat sheet metal tends to buckle and get out of shape with every change in temperature. The corrugations, made in one direction, give it greatly increased stiffness and adapt it to numerous purposes for which it would otherwise be less

suitable. The sheet metal is corrugated by passing between ridged rollers, whose ridges are opposed like the teeth of gear-wheels. It comes out in the commercial form, and is frequently subjected to a process of coating with zinc, to protect it from oxidation, and is then known as galvanized corrugated iron. It is used widely for roofing and walling barns, sheds, warehouses, and other buildings.

CORRUPT PRACTICES ACTS. The effort to eliminate dishonest, irregular, and criminal methods of influencing public elections has resulted in the enactment of various laws to supplement the common law against bribery and corruption (see **BRIBE**). Such acts enumerate and define the corrupt or illegal practices and fix penalties for the same; they usually include bribery in any form, treating, undue influence, intimidation, personation of voters or aiding and abetting in the same, the making of false election returns, the solicitation of candidates for campaign contributions—save by political committees—the contributing of campaign funds to other than authorized agents, the making or receiving of campaign contributions under an assumed name, the rendering of a false declaration of election expenses, etc. Many laws forbid the acceptance of campaign contributions from certain sources, especially from corporations and from assessments levied on officeholders in the civil service.

British Acts.—Statutes to prevent bribery and corruption have been passed in 1729, 1809, 1827, 1842, 1854, 1868, and 1883. The most important of these are the Corrupt Practices Prevention Act of 1854 (which repealed all previous legislation and dealt especially with the practice of electoral bribery), the Parliamentary Elections Act of 1868, and the Corrupt and Illegal Practices Prevention Act of 1883, which incorporated the act of 1854. The act of 1883 defines and fixes the penalties for the criminal offenses classed as corrupt practices, which consist of bribery of seven different varieties, treating, undue influence and personation, all of which are punishable by fine or imprisonment and by loss of political rights for seven years. If a candidate for a seat in Parliament be found guilty by a trial court of committing or consenting to corrupt practices, his election is void and he is forever debarred from representing the district in Parliament; but should only his agent be proved guilty of corrupt practices, the candidate, though personally innocent, may not be elected for the same constituency for a period of seven years. The sections of the act relating to illegal practices as distinguished from "corrupt" practices are intended to limit election expenses. For boroughs of 2,000 voters the maximum expenditure is fixed at £350 while £650 is allowed for counties with the same number of voters with an extra allowance for each additional thousand in the district. The legal expenditures are enumerated, such as printing and meeting halls, etc., and the number of paid agents is limited. Within 35 days after the election the candidate's agent must file a statement of expenses, certified by the candidate. The corrupt practices law applies equally to parliamentary, municipal, county, and parish council elections, and the punishments provided for minor officials correspond with those imposed on parliamentary candidates; a municipal candidate personally guilty of corrupt practice

is forever incapable of holding office, but if guilty merely through acts of his agents he is incapacitated only for three years.

United States Acts.—The federal government has legislated less regarding corrupt practices than the states, since the latter control most of the election machinery. In 1907 Congress passed an act forbidding corporations to contribute to campaign funds in federal elections; on June 25, 1910 an act was approved providing for publicity of political contributions, requiring each political committee to file a financial statement within 30 days after a national election, and on Aug. 19, 1911 an act amending this act was approved extending its provisions to individual candidates as well as to committees. Candidates for the House of Representatives under these acts were allowed to expend a maximum of \$5,000 and for the Senate of \$10,000. The candidates for the lower house were obliged to file with the clerk not less than 10 nor more than 15 days prior to the election (whether it were a primary election, a nominating convention or a general election) a preliminary itemized statement of receipts and their sources and of expenditures and their objects, besides the more complete statement to be filed within 30 days after the election. The act provided that senatorial candidates must file with the secretary of the Senate (not less than five nor more than 10 days prior to the day on which the state legislature first balloted for such candidate) a similar itemized statement of receipts and expenditures, but since 1913, when the Seventeenth Amendment to the Constitution, providing for direct election of senators, was declared in force, senatorial candidates follow the practice of the representatives.

The federal act of 1925 specifically repealed all previous acts and enacted that the treasurers of all political committees operating in more than one state must file sworn statements showing the addresses of all contributors of one hundred dollars or over with the clerk of the House of Representatives on certain specified dates; also the names and addresses of all persons receiving ten dollars or more from the funds collected and the purpose of such disbursements must be stated. Candidates for both Senate and House are required to file itemized statements of all contributions to their campaign at stated times before and after elections. The act fixed \$10,000 as the maximum amount that may be expended by a senatorial candidate and \$2,500 by a candidate for the House of Representatives or an amount reached by multiplying by three cents the number of votes cast at the last general election for the office sought, but not to exceed \$25,000 for a senator or \$10,000 for a representative. Certain types of political promises are also forbidden, such as promise of employment in return for votes. National banks are forbidden to contribute at elections at which members of the Congress or presidential electors are chosen. Corporations organized under authority of the Congress are also forbidden to contribute toward the election of presidential electors or of members of the Congress. Members of Congress, congressional candidates, and other officers and employees of the government are forbidden to solicit campaign contributions directly or indirectly from officers or employees of the government.

Various proposals relating to the amendment of the Corrupt Practices Act of the United States

government were made, but only minor amendments were adopted until 1939.

HATCH ACT

The measure popularly known as the Hatch Act was passed by both houses of the Congress in 1939 and signed by the president. Amendments were adopted in 1940. The name attached to these acts came from their chief sponsor in the Senate, Senator Carl A. Hatch, of New Mexico.

Both the original act and the amendments thereto mark important developments in the election laws. Briefly they provide:

1. That it shall be unlawful for any person to intimidate, threaten, or coerce, or attempt to intimidate, threaten, or coerce any other person for the purpose of interfering with the right of such other person to vote or not to vote as he may choose in any election at which federal officials are chosen.

2. That it shall be unlawful for any person employed in any administrative position of the United States government, or any department thereof, or any person employed in any administrative position of any state government in connection with an activity financed in whole or in part by loans or grants by the United States, to use his official authority for the purpose of interfering with or affecting the election or nomination of any candidate for the office of president, vice president, presidential elector, member of the Senate, or member of the House of Representatives, or delegates or resident commissioners from any territory or insular possession.

3. It shall be unlawful for any person directly or indirectly to promise employment or work provided for or made possible in whole or in part by any act of Congress, as a reward for any political activity; and another section of the act makes it equally unlawful to threaten to withhold any work or employment on account of any political activity.

4. It is likewise made a violation of law to deprive, attempt to deprive, or threaten to deprive by any means, any person of employment or work, whose work or employment is made possible by any act of Congress appropriating funds for work relief or relief purposes, on account of "race, creed, color, or any political activity in support of or opposition to any candidate or any political party in any election." Another section of the act expressly prohibits the soliciting or receiving of any assessment or contribution for political purposes from any person known to be receiving compensation or employment from funds appropriated by an act of Congress for work relief or relief purposes.

5. Copied from the rules of the Civil Service Commission with reference to the employees of the federal government in the competitive civil service, the original act provides: "No officer or employee in the Executive branch of the federal government, or any agency or department thereof, shall take any active part in political management or in political campaigns." While there are certain exceptions to this rule enumerated in the act, the effect of it is to withdraw from political activity practically all the employees of the federal government.

In substance, the foregoing provisions are contained within the original act passed in 1939. In 1940, the Congress extended the same rules and prohibitions to employees in the states who

exercise functions in connection with any activity financed in whole or in part by federal funds. With the exception of the provisions of the law prohibiting political activity on the part of employes, violations of the other sections are made criminal offenses; violations of the provisions relating to political activity are punishable by loss of position or by suspension without pay for not less than 90 days.

Certain provisions were included in the act of 1940 which did not relate to the original act passed in 1939. These new provisions struck directly at the use of excessive campaign funds. During the debate, Senator John Hollis Bankhead, of Alabama, offered an amendment, which was adopted, by which it was declared to be unlawful for any person directly or indirectly to make contributions in an aggregate amount in excess of \$5,000 during any calendar year in connection with any campaign for nomination or election to or on behalf of any candidate for an elective federal office. Violation of this provision of the law carries a penalty of a fine not to exceed the sum of \$5,000 or imprisonment for not more than five years.

When the bill as it passed the Senate, including the Bankhead amendment, went to the House of Representatives, the House added a new provision relating to expenditures by campaign committees. In substance, the House amendment provided: "No political committee shall receive contributions aggregating more than \$3,000,000, or make expenditures aggregating more than \$3,000,000 during any calendar year." That section provides that the penalty set forth in section 302 of the federal Corrupt Practices Act of 1925 shall apply to its violations.

Another interesting amendment was added in the House of Representatives. It makes it unlawful for any person, partnership, or corporation to purchase or buy goods, commodities, advertising, or other articles of any kind, where the proceeds of such purchase would directly or indirectly inure to the benefit of or for any candidate for an elective federal office, or any political committee, or any organization engaged in furthering or advancing the nomination or election of any candidate for any such office, or the success of any national political party. This provision prohibiting the sale of advertising and commodities originated from certain practices engaged in by both the Democratic and Republican parties in times past. It had been the custom to prepare more or less elaborate books dealing with the national conventions. Advertising in these convention books was sold to the extent that the method became a rather effective means of raising campaign funds. The method had long been criticized as an evasion of the Corrupt Practices Act with reference to contributions to campaign funds by corporations. Corporations had long been prohibited from making campaign contributions, but in many instances corporations subscribed and paid for space in the convention books. Sponsors of the legislation insisted such practices were intended to be prohibited by the Corrupt Practices Act; they sought to completely outlaw such transactions.

The criminal sections of these acts are enforced through the Department of Justice in the ordinary criminal law enforcement methods.

The provisions of the law relating to prohibiting political activity on the part of federal em-

ployes are enforced by the various departments. The Civil Service Commission has concurrent enforcement jurisdiction in the case of persons occupying position in the competitive civil service.

In the provisions of the 1940 amendments which relate to employes within the states, who are not technically federal employes but whose employment is made possible by the use of federal funds, a difficult question of enforcement arose. Obviously, the federal government has no power to compel the discharge of any employe within the states; neither would it seem proper to leave the enforcement of the federal statute entirely to state authorities. Finally, it was decided to provide for enforcement by and through the Civil Service Commission of the United States. Therefore, the Civil Service Commission was charged with the responsibility and duty of enforcing those provisions of the law which deal principally with employes within the states. Provisions providing for hearing before the Civil Service Commission are set forth in the act; and after such hearing, the commission must determine whether any violation has occurred. On such finding, the appropriate state official is notified; and if the offending employe is not removed within 30 days after notice of such determination by the commission, the appropriate federal agency is required to withhold from the federal funds supplied to such state agency an amount equal to two years' compensation at the rate such officer or employe was receiving at the time of the law's violation.

Probably never before in the history of the country has drastic legislation of the kind described ever been enacted at a time when a national campaign was approaching. In the beginning, the proposed legislation was not regarded very seriously; final passage of such measures was not deemed to be possible.

According to the sponsors of the legislation, the principle embraced in these laws is not new; political activity of federal employes in the classified civil service has long been prohibited. The extension of such prohibitions to employes in the states is new. Those features of the bill were sharply criticized and extensive debate was held in both branches of Congress. The principal objection was based upon the grounds that following federal funds into the states invaded the doctrine of states' rights. Sponsors of the legislation defended it vigorously on the grounds that no invasion of states' rights was involved. The simple theory is that the federal government, having prohibited its own employes from political activity, wished to extend these same prohibitions to employes in the states whose employment is made possible by federal funds.

The whole purpose of this legislation is to strike a direct blow at what is commonly known as the spoils system. Advocates of the legislation contend that by removing employes in active political life, one of the greatest obstacles toward the establishment of a genuine system of merit will be removed.

Senator Hatch himself severely criticizes the spoils system in federal, state, and local governments. He advanced the legislation upon the theory that it would lead to further progress in the development of the merit system, not only in the federal government but in the several states and municipalities. "The objective in this regard is not fully accomplished by the legislation thus far enacted," the author states. "It will take

more legislation and development and correction within the merit system itself to accomplish that, even in the federal government alone."

To carry out the complete objective will require separate laws in the states themselves. In this connection, it is interesting to note that the movement started in the federal government has already reached into several states. New York State, for instance, has passed a law putting many of the provisions of the federal legislation into effect in that state. Several other states have enacted similar legislation.

It is not too early to determine the effect of such legislation in political campaigns. Campaign funds have been partially curtailed. It is possible that large contributions from individuals may hereafter be made by ruse or evasion, but excessively large campaign contributions will be the exception rather than the rule, as has been the case in the past. It is believed by many that the progress made by this type of legislation will be continued, that other laws carrying out the general aims of this legislation will be more easily enacted, and that a definite start or beginning has been made. See also CIVIL SERVICE.

CARL A. HATCH,

United States Senator from New Mexico.

EDITORIAL NOTE: The Taft-Hartley Act of 1947 prohibits labor unions from making contributions or expenditures from union funds in connection with an election to political office.

STATE LAWS

All the states and territories have enacted corrupt practices acts of some sort. The earlier laws related chiefly to bribery, betting on elections, etc., but the latest laws so carefully regulate expenditures by party candidates and committees and define legal and illegal practices with such particularity that few loopholes exist for "honest graft," the most tempting opportunity for evading the law being furnished by the allowances for "necessary personal expenses" (comprising expenditures for traveling, stationery, postage, express, telephone and telegraph services, etc.), which need not be included in the financial statement.

New York was the first state to legislate against corrupt practices at elections, passing an act in 1890 requiring candidates to file itemized statements of expenditures on pain of imprisonment and loss of office. As the operations of political committees were not restrained by this law, the defect was remedied by a supplementary law providing that within 20 days after the election the treasurer of such committee shall file an itemized statement giving amounts of contributions with names of donors and details of all expenditures over \$5 with the objects and names of persons to whom payment was made. Bribery, personation, illegal registration, the use of false naturalization papers, and the aiding of another to do so are punishable by imprisonment not exceeding five years, while giving a bribe also disqualifies for holding office and receiving a bribe disfranchises for five years. Illegal primary voting is a misdemeanor as is making a false declaration of party affiliation. The amounts that candidates for various offices may spend are carefully listed, graded and defined, as are also the legitimate expenses that may be incurred by all others connected with the elections. In 1909 New York also prohibited all corporations, save political associations, to make campaign contributions

or to expend money for any political purpose whatsoever, and an officer, stockholder or agent of any corporation guilty of such practice may be imprisoned for one year and fined a sum not exceeding \$1,000. Candidates may not be solicited for contributions nor are judicial candidates allowed to donate. Influencing voters by promising employment or office was first prohibited by Massachusetts, which also forbids the publication of unsigned political advertisements, the subsidizing of newspapers to favor a particular candidate, the contribution of funds to political parties by certain corporations, and the payment of naturalization fees by political committees.

Several states prohibit electioneering on election day and the giving away of liquor within a certain distance of the polling places, and a few states now bear a part of the election expenses. Oregon limits the amount to be expended on an election and pays part of the expenses of informing voters about candidates and parties. In 1909 Colorado provided that only the state and the candidates should pay the expenses of electing state, district and county officers at general elections. Each political party receives from the state 25 cents for every vote cast for governor by that party in the preceding election, the money being paid to the state chairman who is bonded to guarantee the legitimate use of such funds and also to vouch that one half of the sum received by him is distributed among the county chairmen. Candidates may personally contribute a sum regulated in accordance with the amount of the prospective salary or fees. Other persons or corporations contributing to any party candidate or committee or receiving such contributions are guilty of felony. In 1915 Nevada limited the expenditures of any party to \$15,000 during one campaign. In the same year Kansas prohibited a candidate from spending more than 10 per cent of the office salary for the first year, on expenses other than travel. This state also forbids any candidate or organization to provide conveyances to take voters to the polls. California penalizes frauds in connection with initiative, referendum and recall petitions, making such practice a felony punishable by imprisonment for from 1 to 15 years. Most of the states require the publication of financial statements at specified intervals before election day and complete sworn statements within a certain time after election, various penalties being imposed for failure to comply. Nebraska requires not only the itemized statement to be issued 15 days before election but also daily reports thereafter until election of all contributions over \$25. In 1911 Indiana provided that candidates must conduct their financial operations through "political agents" to prevent the irresponsible distribution of political funds. South Dakota requires a secretary for each political committee who must receive all contributions, transfer them to the treasurer and approve all vouchers before the latter officer may expend the funds. Most states require that these statements be open to public inspection. See also BALLOT; BRIBE; ELECTION FRAUDS, SAFEGUARDS AGAINST; LOBBY.

CORRUPTION OF BLOOD, in law, the incapacity to inherit, or pass an inheritance, in consequence of an attainder to which the party has been subject. In the United States it was abolished by the federal Constitution. See **ATTAINDER**; **FORFEITURE**.

CORRY, city, Pennsylvania, in Erie County; altitude 1,429 feet; on the Pennsylvania and the Erie railroads; 36 miles southeast of Erie. The surrounding area is devoted chiefly to agriculture and dairying. Development of the Pennsylvania oilfields contributed to the growth of the town, the industries of which include making airplane parts, oil drilling engines, machines, springs, and steel furniture. There is a public library. The state fish hatchery is nearby. Corry was settled in 1860 and named for Hiram Corry, one of the first settlers. Incorporation as a city took place in 1866. The water, power, and light systems are privately owned. Government is administered by a mayor and council. Pop. (1930) 7,152; (1940) 6,935; (1950) 7,872.

CORSAC, kôr'sāk (*Vulpes corsac*), a species of fox or dog found in central Asia, Siberia and Mongolia, sometimes called the steppe-fox. Its color varies from reddish-yellow in summer to a whitish tinge in winter. The Kirghiz hunt the corsac for its soft, thick, warm fur. It is gregarious, prowls by day, burrows and lives on birds and eggs. The corsac is often seen in zoological gardens. It is much like the American kit-fox (q.v.) in its habits.

CORSAIR, kôr'sâr (Fr., in origin identical with "courser" or "cruiser"), a term employed to denote pirates or their vessels. By the princes of the coast of Barbary the corsairs of their states were commissioned to attack the merchant ships of foreign nations, and they became the scourge of the Mediterranean. See **BARBARY POWERS**, **UNITED STATES TREATIES AND WARS WITH THE**.

CORSAIR, *The*, poem in heroic couplets by Lord Byron, published in 1814. Conrad, pirate chief on an Aegean island, though a man of many vices, is brave and chivalrous. A characteristically Byronic tale, it was extravagantly praised by Mme. de Staël, Stendhal, and Vigny.

CORSE, kôrs, John Murray, American military officer: b. Pittsburgh, Pa., April 25, 1835; d. Winchester, Mass., April 27, 1893. He was a cadet at West Point for two years, and in 1860 became a lawyer, but enlisted in the Union Army at the outbreak of the Civil War. He was a brigadier general in 1864; commanded a division in Georgia, and upon the advance of the Confederates against Allatoona, Sherman helio-

graphed him, "Hold the fort for I am coming," which inspired Philip P. Bliss to compose the famous hymn *Hold the Fort*. General Corse repulsed the enemy and accompanied Sherman on the march to the sea. After the war he was successively collector of internal revenue in Chicago and postmaster of Boston.

CORSET, kôr'sêt, an article of dress worn generally by women for the purpose of keeping the form erect and trim. It is usually made of two thicknesses of white jean, silk, nylon, or other material, stiffened by whalebones or steels or it may be made wholly or in part of elastic or webbing. It was used in Germany in the Middle Ages, and was introduced into France about the time of the Revolution. At an early age it was in use in Great Britain and Ireland, at least in the 18th century, and was worn by little girls as a support for the body. The styles of corsets have changed with the styles of dress, the modern tendency being to emphasize the natural figure. Rubber corsets are used as flesh reducers.

CORSICA, kôr'si-kâ (Fr. *CORSE*), an island and French department in the Mediterranean Sea. It is separated from the island of Sardinia, on the south, by the Strait of Bonifacio, about 10 miles wide, and its shortest distance from the mainland is 50 miles. It is distant from France about 100 miles. It is somewhat irregular in shape, but tolerably compact, except toward the north, where it terminates in a long and narrow tongue of land about 22 miles long by about six miles broad. Greatest length, north to south, 114 miles; greatest breadth, near its center, 53 miles; area, 3,367 square miles. The east coast is remarkable for its uniformity, presenting a line which is broken in only one or two places by comparatively small indentations. To this the west coast presents a striking contrast, a number of deep bays following each other in rapid and almost uninterrupted succession. Of these the most important, proceeding north to south, are the gulfs of Saint Fiorenzo, Calvi, Porto, Liscia Ajaccio and Valinco. The interior is traversed by a mountain chain, which has its principal direction north to south, but throws out several lateral branches, particularly to the northwest. The highest summits are near the center of the island, including Mont Cinto, 8,881 feet, and Mont Rotondo, 8,612, while others exceed considerably 7,000 feet and the greater part of the year are covered with snow. The mountain masses are chiefly composed of granite and porphyry, and appear to be generally overlaid by extensive beds of limestone. From the east and west sides of the chain numerous streams descend to the opposite sides of the coast. They are mere torrents, short and rapid, and altogether unfit for navigation. The largest are the Golo and Tavignano. Along the river mouths large quantities of debris and alluvium have accumulated which, preventing the egress of the waters, have gradually formed on the east coast a series of lagoons and morasses and made that part of the island very unhealthy; but with this exception the climate is one of the finest in Europe. The heat is sometimes excessive, but the sky is generally clear and the air bracing. The summits of its many lofty mountains are covered with pines, evergreen oaks, cork trees, beeches and chestnuts. In other

parts the hillsides are overgrown with dense thickets of cistus, myrtles, arbutus and other shrubs. Numerous valleys lie between the lofty ridges, and sometimes plains of considerable extent occur, the soil of which is generally fertile and well adapted for the growth of all the ordinary cereals. Agriculture is in a backward state, and the island produces scarcely a sufficient amount for local consumption. Large tracts of land are uncultivated; the farming implements in use are of the crudest form. The slopes are covered with vineyards, and the olive trees appear to be indigenous. The mulberry, orange and citron succeed well, particularly in the lower valleys near the coast. One of the most valuable productions of the more elevated districts is the chestnut, on which, at least during the winter months, the poorer inhabitants principally subsist.

Among domestic animals, the first place for usefulness and numbers is due to mules and goats. The principal wild animals are the boar and the fox. Deer are numerous and all the smaller game and wild fowl are common; eagles, vultures and numerous other birds of prey frequent the mountains, and fish abound. The principal source of mineral revenue is derived from quarries of fine granite, porphyry and marble. Neither manufactures nor trade have made much progress. The chief exports are wine, brandy, olive-oil, chestnuts, fruit and fish. The inhabitants have the reputation of being haughty in temper, passionate and revengeful. Corsica is one of the countries in which the *vendetta* obtains, the taking of private vengeance for the blood of a relative, of which a striking picture is to be found in Merimée's *Colomba*.

From the Phoenicians, its first colonists, the island took the name of Cynos; and from the Romans that of Corsica. On the decline of the Roman empire it was seized by the Goths and passed from them to the Saracens. In 1481 it fell under the dominion of the Genoese, who retained it, with some interruption, till 1755, when a great part of it was wrested from them and made independent by the celebrated Gen. Pasquale Paoli. France, claiming it on a pretended cession by the Genoese, obtained forcible possession of it in 1768, after the inhabitants had distinguished themselves by a long and valiant resistance. At the time of the French revolution, Paoli, who had taken refuge in England, returned to his native land, and unfurling the banner of the death's head (the old Corsican arms), he summoned his countrymen to strike for their independence. With the assistance of the British, who landed Feb. 18, 1794, he reduced Bastia in May and Calvi in August. Corsica was constituted a kingdom under the government of a viceroy (General Elliot); the constitution and laws of Great Britain were adopted, and a parliament such as Ireland had was established. But a large part of the people were averse to the British, whom they regarded as heretics, and the French party again appeared on the island in October 1796. Sickness had reduced considerably the effective force of the British, and their position was rendered still more critical by the French occupation of the neighboring city of Leghorn, and in consequence they evacuated Corsica. In 1814 it was again in British occupation.

Since 1815 the island has formed a French department. For administrative purposes it is

divided into four arrondissements—Ajaccio (the capital), Bastia, Corte and Sartène, subdivided into 62 cantons and 364 communes. The greatest individuals to whom Corsica has given birth are Paoli and Napoleon. Pop. (1946 est.) 267,873.

CORSICANA, kôr-sî-kân'â, city, Texas, seat of Navarro County; altitude 448 feet; on the Saint Louis Southwestern, Southern Pacific and the Trinity and Brazos Valley railroads, and two federal and two state highways, 60 miles south of Dallas. An Odd Fellows Orphans' and Widows' Home and the State Orphan Home are here. Three charitable trusts amount to about \$2,000,000. The adjacent territory raises cotton, grain, fruit, cattle, and sheep; and has been producing oil since 1895 from shallow wells, but since 1923 from deep wells. Fuel oil and natural gas are extensively used for heat and power production. Corsicana has large oil refineries, cotton and cottonseed-oil mills, oil-well and oil-field supply houses, brick plants, cotton gins, lumber yards, a farm-implement factory, cotton warehouses, a chili factory, etc. The county was named for J. Antonio Navarro, who came from Corsica—and Corsicana means Corsican. The city is governed by a mayor and a commission. Pop. (1940) 15,232; (1950) 19,211.

CORSINI, kôr-sē'nē, **FAMILY**, a famous Florentine family, known since the 13th century.

SAINT ANDREA: b. Florence, Nov. 30, 1302; d. Fiesole, Jan. 6, 1373. He early entered a monastery in Florence, where he remained for 40 years; he was then made bishop of Fiesole and sent as a papal legate to Bologna, where he was successful in making peace between factions and putting an end to civil war.

LORENZO (1652-1740), became Pope as Clement XII (q.v.). He restored the Corsini Palace in Rome now containing the interesting Corsini Gallery.

TOMMASO, Italian politician: b. Rome, Nov. 5, 1767; d. there, 1856. He was a supporter of Pope Pius IX and was made senator (chief magistrate) of Rome; when the pope fled from Rome, Corsini went to Florence for a time, but later returned to Rome.

His brother **NERI**: b. 1771; d. 1845, was a member of the council in Tuscany under the grand dukes Ferdinand III and Leopold II.

NERI, Italian politician: b. Florence, Aug. 13, 1805; d. Dec. 1, 1859. He was the younger son of Thomas Corsini and became one of the leaders of the Liberal party in Tuscany. In 1848 he was minister of war and foreign affairs; later the Grand Duke Leopold II offered him the first place in the ministry and he immediately proposed to establish the constitution. The duke, however, would not consent to this and went into exile. The provisional government then organized sent Corsini to London to represent Tuscany there.

CORSNED, kôrs'nēd, or **MORSEL OF EXECRATION**, a form of trial or purgation formerly made use of in England. See **ORDEAL**.

CORSO, kôr'sô, an Italian term first applied to races of riderless horses, then to the long lines of gaily decorated carriages driven through the principal streets of the cities, and afterward to the most fashionable carriage-drive in the city. The Corso at Rome, stretching from the Piazza del Popolo to the Capitol, and dividing the city

into the two equal parts, is nearly 3,500 paces in length, and is flanked by many high and splendid edifices; but its breadth is not proportionate, so that in most parts no more than three vehicles can go abreast.

CORSSEN, kôr's'en, **Wilhelm Paul**, German philologist: b. Bremen, Germany, Jan. 20, 1820; d. Berlin, June 18, 1875. After studies in philology at Berlin and two years of teaching at Stettin, he was called in 1846 to lecture at Schulpforte, where he remained until 1866, when ill health compelled him to retire. His earliest important work was his treatise on the pronunciation and accent of Latin, *Über Aussprache, Vokalismus und Betonung der lateinischen Sprache* (1858-1859; 2d ed. 1868-1870), for which he received the prize offered by the Royal Prussian Academy of Sciences for the best work on that subject. His *Über die Sprache der Etrusker* (1873-1875), in which he labored with great ingenuity and vast learning to prove against the world that the Etruscan language was cognate with that of the Romans, started a controversy in which his arguments were violently opposed by classical students everywhere.

CORT, kôrt, **Cornelis**, Dutch engraver: b. Hoorn, Netherlands, ?1536; d. Rome, Italy, 1578. After working in his youth for a printseller at Antwerp, he went to Venice in 1566 and was warmly welcomed by Titian, some of whose pictures he was employed to engrave. Cort finally settled at Rome in 1571 and established a school of engraving there. He made the first engraving of Raphael's *Transfiguration* and about 150 prints from other Italian and Flemish masters, including Correggio, Maarten van Heemskerck, the miniature painter Giulio Clovio, and Michelangelo. Agostino Carracci was his pupil. His work was not superseded until the advent of Hendrik Goltzius. The number of Cort's engravings, considering the shortness of his life and the size and fine style of the plates, betokens a considerable amount of industry; but although he had a complete mastery of engraving, he is criticized for deficiency in discriminating delicate shades, relative distances, and the nice varieties of expression.

CORT, Frans de, Flemish poet: b. Antwerp, Belgium, June 21, 1834; d. near Brussels, Jan. 18, 1878. As a singer of the quiet joys of home life and conjugal happiness he has few peers in any literature. His original homely lyrics appeared in *Liederen* (1857-1859), *Zing-Zang* (1866), and another volume of *Liederen* (1868). He also translated into Flemish verse *The Finest Songs of Robert Burns* (1862), the *langue d'oc* songs of the Gascon poet Jacques Jasmin, and some German verse. In 1861 he founded the periodical *De Toekomst* (*The Future*). He edited the posthumous poems of Johan Michiel Dautzenberg, his father-in-law, in 1869.

CORT, Henry, English ironmaster and inventor: b. Lancaster, England, 1740; d. London, May 23, 1800. Having at an early age conceived the idea of making England independent of foreign countries for its supply of iron, he established himself as an iron merchant at Gosport, Hampshire, and in 1775 erected ironworks at Fontley, near Gosport. There he expended large sums on the development of processes for improving and increasing the production of iron. During 1783

and 1784 he perfected the first process which made use of grooved rolls for the removal of slag and a method of puddling iron that produced much greater quantities than had previously been possible. He took into partnership Adam Jellicoe, chief clerk in the office of the paymaster of the navy, but after his partner's death the navy board seized his ironworks for claims against Jellicoe, involving Cort in lawsuits and eventually in total ruin. After his death, his family received insignificant pensions from the government. He is sometimes called "the father of the iron trade," and his inventions contributed much to England's industrial greatness in the 19th century.

CORTE, kôr'tâ, town, Corsica, on the Tavignano River, 35 miles northeast of Ajaccio. Picturesquely situated among the mountains, the town is partly built on a steep rock crowned by a 15th century citadel. It was the seat of the Corsican patriot Pasquale di Paoli's reform government from 1755 to 1769. An ancient palace from which Paoli ruled and an old Franciscan monastery which served as the parliament house in 1765 still remain. Corte produces lumber, wine, and briar pipestems. Pop. (1946) 5,089.

CORTE-REAL or **CORTERREAL**, kôr'tê-rê-âl, **Gaspar**, Portuguese explorer: b. about 1450; d. about 1501. In 1500 he was sent out by King Emanuel (Manuel I) in search of the Northwest Passage. Setting out from Lisbon, he ranged the shores of the country afterward called Canada. On his second voyage, in 1501, he sent back two ships but never returned himself. His brother Miguel, who sailed in search of him in 1502, was never afterward heard from. King Emanuel sent an expedition to learn their fate but in vain.

Consult Biggar, H. P., *Voyages of the Cabots and the Corte-Reals* . . . (Paris 1903).

CORTELYOU, kôr't'l-yō, **George Bruce**, American public official and business executive: b. New York, N. Y., July 26, 1862; d. Huntington Bay, Long Island, Oct. 23, 1940. After being graduated from the State Normal School, Westfield, Mass., in 1882, he taught school in New York City and entered public service in 1889, serving as assistant to several New York and federal officials. In 1895, he received the degree of bachelor of laws from Georgetown University, Washington, D.C., and in the same year became stenographer to President Cleveland. In 1900 he was appointed secretary to President McKinley, and President Theodore Roosevelt continued him in that office until 1903, when he became first secretary of the Department of Commerce and Labor. Under President Roosevelt he also served as postmaster general (1905-1907) and as secretary of the treasury (1907-1909). He left government service in 1909 and was president of the Consolidated Gas Company of New York until 1935.

CORTES, kôr-täs', **Hernán**, ěr-nân' (also **HERNANDO** or **FERNANDO CORTEZ**), Spanish conqueror of Mexico: b. Medellín, Extremadura, Spain, 1485; d. Castilleja de la Cuesta, near Seville, Spain, Sept. 2, 1547. A descendant of the country's minor nobility, he was sent in 1499 to the University of Salamanca to study law. After two years of irregular studies he decided to seek a life of adventure and planned to participate in a

military expedition to Italy, but had to stay behind on account of a sudden illness. Upon his recovery he set out, in 1504, for Hispaniola (Santo Domingo) in the West Indies, where he assisted his kinsman, Nicolás de Ovando, in several campaigns against the Indians. In 1511 he joined Diego Velázquez in the conquest of Cuba and was named by the latter mayor of the recently founded city of Santiago de Cuba.

When Velázquez got news of Juan de Grijalva's successful exploration of Yucatán, he entrusted Cortés with the conquest of Mexico. Later, however, he reversed the commission. Disregarding the orders of the governor, Cortés set sail from Santiago in February 1519 with a fleet of 11 vessels, manned by about 700 Spaniards and armed with 10 small field pieces. With him he took 18 horses which proved of inestimable value, since these animals were then unknown to the Indians of America. Following in the footsteps of Grijalva he landed first off Yucatán and then reached Tabasco, where the natives gave him 20 slave girls. One of these maidens was the beautiful Malinche (renamed Marina) who spoke several native languages and who bore him a son. After having built the fortified port of Villa Rica de Vera Cruz (today Veracruz), he established there his own government independent of Velázquez, appointed himself captain general, and, to give his soldiers the courage of despair, caused his little fleet to be destroyed. Then he began his conquest of the extensive Aztec empire of Anáhuac or Mexico.

The sight of mounted, ironclad white men and the noise of their cannons alarmed and stupefied the natives. The adventurer quickly defeated the Tlaxcalans, the perennial enemies of the Aztecs, and the Tlaxcalans became his faithful allies to the last. After avoiding a trap at Cholula, Cortés entered the city of Mexico, then called Tenochtitlán, on Nov. 18, 1519. Montezuma II, the sovereign of the country, received him graciously, and the inhabitants, recalling the legend of the return of the white god Quetzalcoatl, thought him a divinity and a child of the sun. Cortés did nothing to dispel these illusions. Instead he demolished the idols in the temples and replaced them with images of the Virgin and the saints. In the meantime he made continual progress toward getting possession of the country, forming alliances with several caciques (chieftains) who were enemies of Montezuma. When he received notice that an Indian force, in obedience to a secret order by Montezuma, had attacked Veracruz and sent the head of a Spanish warrior to the capital to prove the white man's mortality, Cortés repaired to the imperial palace, had the commander and officers of the offending Indian expedition burned alive, and compelled the emperor, in chains, to acknowledge publicly the sovereignty of Charles V of Spain. The unhappy monarch had to add to his homage a large quantity of pure gold and a number of precious stones.

Early in 1520 Velázquez, jealous of the successes of his insubordinate representative, sent against him a detachment of about 1,000 men led by Pánfilo de Narváez. These were immediately won over by Cortés who had hastened to the coast to meet them, leaving Pedro de Alvarado in command at Tenochtitlán. The latter's cruel regime led to an open revolt of the Aztecs, and Montezuma, who attempted to restore tranquillity by showing himself to the multitude, fell a victim to their wrath. Cuauhtemoc (Guatemotzin), his

nephew and son-in-law, was acknowledged as emperor by the Mexicans. Under his leadership fighting continued after the conqueror's return to Tenochtitlán. On the famous *noche triste* (dismal night), June 30, 1520, Cortés had to abandon the city. However, a decisive victory over the Mexicans at Otumba soon after restored his hold, and after a three-month siege he again took possession of the capital (Aug. 13, 1521), which was laid in ruins and later rebuilt as a Spanish city. Cuauhtemoc and a great number of his nobles were subjected to torture and later executed. The subjection of the rest of the empire proved an easy task. The infamous *repartimiento* system was inaugurated, and the Indian population was treated little better than slaves. Cortés undertook several expeditions to remote parts of Mexico, then called the Viceroyalty of New Spain, and penetrated as far as Honduras.

The court of Madrid, lending an ear to the charges of his rivals, now became suspicious of the power of Cortés who had some time before been appointed captain general and governor of New Spain. To clear himself, Cortés went to Spain. During his stay there (1528–1530) he was received with much distinction by Charles V and named marqués del Valle de Oaxaca, and he returned to Mexico with an increase in titles, but a diminution of power. The viceroy had charge of civil administration, while Cortés was entrusted only with the military command and the privilege of pursuing his discoveries. Though he discovered (1536) the peninsula of Lower California and the intervening Gulf of California, most of his enterprises were frustrated, particularly since the installation of the able Antonio de Mendoza as viceroy. Embittered, he returned in 1540 to Spain, where he was coldly received and neglected. He followed Charles V on his unfortunate expedition against Algiers in 1541 and gave signal proofs of his valor, yet the monarch continued to refuse him admission to the court. It is said that one day, when he forced his way through a crowd around the carriage of the king, and put his foot on the step to obtain an audience, Charles coldly inquired who he was. "I am a man," replied Cortés, "who has gained you more provinces than your father left you towns." He passed the remainder of his days lingering around the court in a vain effort to recover the sums he had spent out of his personal fortune in the New World. At his death he left a reputation as a great 16th century man of action, bold and able, but not lacking in cruelty and even perfidy. Buried in Seville, his remains were later brought to Mexico City. His natural son by Marina, called Don Martín Cortés, became a knight of the Order of Santiago.

CORTES, kôr'tez, the old assembly of the "estates" in Spain and Portugal, the representa-

tives chosen by the three estates (nobility and clergy, to which were added the burghers in the 12th and 13th centuries) to assist the king in making and administering the laws. These parliaments seem to have grown out of the councils composed of nobles which advised the Visigoth kings. During the division of the Iberian Peninsula into various kingdoms, including Portugal, they exercised considerable power, which continued during the period of reconquest from the Moors. But following the territorial consolidation of Spain in the 15th century and the growth of royal supremacy in both Spain and Portugal, their power declined. The vast wealth of the Spanish and Portuguese colonies made the kings less dependent on the parliaments for subsidies, and they were summoned less and less frequently.

In Spain the Cortes of Castile, which was composed of the higher nobility, the superior ecclesiastics, the knights of the orders of Saint James, Calatrava, and Alcántara, and the representatives of certain cities, held the first rank during the time of the united Spanish monarchy. In early times the king was very dependent upon the Cortes; indeed, it was invested with the power of making war and frequently exercised it in opposition to the throne. In the original constitution of Aragon, where the Cortes was very powerful, a supreme judge, called the *justicia*, presided over the administration of the government. He decided all questions and disputes between the king and his subjects, and confined the royal power within the constitutional limits. King Ferdinand II of Aragon and Isabella of Castile succeeded in rendering themselves independent of the Cortes; and afterward, when the Castilians dared to resist an unconstitutional tax at a meeting convoked at Toledo by Charles V in 1538 the emperor abolished this assembly of the estates. After this neither the clergy nor nobility were assembled. Deputies from 18 cities were sometimes, however, convened, but this only in case subsidies were to be granted. Philip II restrained the liberties of the Aragonese in 1591. After the War of the Spanish Succession, Philip V deprived those provinces which had adhered to the anti-Bourbon party of the privileges that still remained to them. From that time the Cortes were convened only to pay homage to the king or the prince of Asturias, or when a question respecting the succession to the throne was to be determined.

The national Cortes elected in 1810 at Cádiz, in the only section of Spain then free from Napoleon, promulgated a liberal constitution on May 8, 1812, while the Anglo-Spanish liberation of the kingdom was still under way. Ferdinand VII, returning two years later, abrogated this constitution, and a period of monarchist reaction followed. Thereafter, with short intervals of power, notably during the chaos of the First Spanish Republic (1873-1874), the Cortes was under royal or military domination. A single-chamber Cortes was the parliament of the Second Spanish Republic (1931-1939). It was re-established by Francisco Franco in 1942, but was stripped of its powers under his dictatorship. See also SPAIN—*Government; History*.

Burghers were admitted to the Cortes of Portugal by King Diniz (r. 1279-1325). The medieval parliament held substantial power, due in part to its privilege of approving the succession to the throne, during a period marked by revolts and civil wars until the end of the 15th

century. The accession of John IV, following a period of Spanish rule (1580-1640), marks the decline of the Cortes, the last of the time being summoned in 1697.

As in Spain, the period following the Napoleonic Wars saw a struggle between liberals and reactionary monarchists. A Cortes briefly held considerable power, 1820-1823, and another, 1826-1828, when absolutism was reinstated by Don Miguel.

The National Assembly of Portugal, established along corporative lines in 1933 under the dictatorship of Antonio de Oliveira Salazar, is the Cortes Gerais. See also PORTUGAL—*History*.

CORTEX, a protective layer of tissue occurring in the stems of dicotyledonous plants, situated between the pericycle outside the phloem and the epidermis. The name has been applied loosely to any outer layer of stem tissue, but it is better usage to restrict it to primary cells and the tissues developed therefrom.

Cortical tissues often are a conspicuous part of bast, which is of economic importance in vegetable fibers and textiles. See also BAST.

CORTEZ, kôr'têz, town, Colorado; seat of Montezuma County; altitude 6,198 feet; 210 miles southwest of Colorado Springs. It is five miles northwest of Mesa Verde National Park, in a region producing cattle, sheep, dairy products, and timber. The Consolidated Ute Indian Reservation is nearby.

Settled in 1887 and incorporated in 1902, Cortez has government by mayor and council. Pop. (1950) 2,680.

CORTHELL, Elmer Lawrence, American engineer: b. South Abington (now Whitman), Mass., Sept. 30, 1840; d. Albany, N. Y., May 16, 1916. When he was in his second year at Brown University the Civil War broke out and he enlisted in the First Regiment, Rhode Island Light Artillery, rising from private to captain during the war. Then he re-entered Brown, obtaining successfully the degrees of B.A., M.A., and in 1894 Sc.D. He took up engineering work, mainly in the Mississippi Valley. After engaging in railroad and bridge construction requiring great skill, he was associated in 1875 with James B. Eads in building the jetties at the mouth of the Mississippi River. Among the many engineering projects in which he participated were the planning with Captain Eads of the ship railway across the Isthmus of Tehuantepec; the building of several large bridges over the Missouri, Ohio and other rivers; the opening of the Amazon River and the designing of the harbor works at Tampico, which raised that port to the first rank in Mexico.

CORTINA, kôr-tê'nâ, Juan Nepomuceno, Mexican adventurer: b. Camargo, Tamaulipas, 1830; d. Azcapotzalco, Federal District, Oct. 30, 1894. He took an active part in the war between Mexico and the United States, organizing a band of independent guerrillas, which later became a part of the national army, and with their commander took part in many of the battles of that contest. After the war he became a general in some of the revolutionary risings, and in 1859 set himself up as an independent ruler along the border line between the United States and Mexico, where he held sway from 1859 until 1863. He became an adherent of the unfortunate

can, and from 1861 to 1864 he was United States minister to Mexico.

CORY, William Johnson (original surname JOHNSON), English schoolmaster and lyric poet: b. Torrington, Devonshire, 1823; d. Hampstead, June 11, 1892. He was a master at Eton (where he had been educated) from 1845 until 1872; in the latter year, having inherited an estate, he assumed the name of Cory. In 1858 he published *Ionica*, a volume of poems containing a notable translation of the epitaph on Heraclitus by the Alexandrian poet Callimachus—"They told me, Heraclitus, they told me you were dead." Other works included *Lucretius* (1871), on the writing of Latin verse; and a *Guide to Modern History from 1815 to 1835* (1882). F. Warre-Cornish edited his *Letters and Journals* (1897).

CORYATE, kōr'i-āt, or **CORYAT**, **Thomas**, English traveler: b. Odcombe, Somersetshire, 1577?; d. Surat, India, Dec. 1617. He was a willing buffoon at the court of James I, and later was a member of the household of Prince Henry, the king's eldest son. During five months in 1608 he traveled, mostly on foot, through much of western Europe, and recounted his experiences in *Coryat's Crudities* (1611), a curious book to which, on the orders of Prince Henry, were appended quizzical verses, in various ancient and modern languages, written by Ben Jonson, John Donne, and other authors. The latter were afterward published separately under the title of *The Odcombe Banquet*, with a preface reflecting satirically upon Coryat. In a second volume, entitled *Crambe or Colwort Twice Sodden*, he protested that the verses were appended to his original work without his consent. He departed on his second journey in 1612, residing for a time at Constantinople, visiting Palestine and Mesopotamia, and reaching Agra, in India, in 1616. In 1905 Glasgow University Press republished *Coryat's Crudities*, with his letters from India.

CORYBANT, kōr'i-bānt, in Greek mythology, one of the beings said to have sprung from Corybas, son of Cybele and Iasion, who appointed them to perform religious service for his mother, the goddess Cybele, in Crete and Phrygia. The Corybantes engaged in wild religious dances to the accompaniment of the music of flutes and cymbals. There were also Corybantes who were regarded as a class of deities resembling the Cabeiri (q.v.), and of whom little is known. According to ancient traditions, they were descendants of Hephaestus (Vulcan). The name is sometimes given to the priests of Cybele, as it was said they imitated the dance of the Corybantes.

CORYDALIS, kō-rīd'ā-līs, a genus of large insects, whose net-veined wings expand nearly six inches. It is a member of the neuropterous family Sialidae, and is named *Corydalus cornutus* in allusion to the enormously long hornlike mandibles of the male, used as claspers in the act of pairing, those of the female being large, but short, broad, and toothed. The larva is called in the northern part of the United States dobson or hellgramite, and among the Mississippi fishermen it is known as crawler; it is much esteemed as bait. The larva lives for nearly three years under stones in brooks; it is nearly three inches

long, with six legs and big jaws, and along each side of the hind-body is a series of long filamentary appendages, at the base of which are short bushy or spongy gills. It breathes by the spiracle during its later larval life, when it lives out of the water. It transforms into a chrysalis in the earth on the banks of brooks. The female lays from 2,000 to 3,000 eggs in a mass. Though very ferocious in appearance, the insect, which sometimes alights on one's dress, is entirely harmless.

CORYDON, kōr'i-d'n, town, Indiana, seat of Harrison County, located on Indian Creek 18 miles west-southwest of New Albany. It is served by the Louisville, New Albany and Corydon Railroad. A sulphur spring here and Wyandotte Caves near by attract tourists. Furniture and cheese are made here. Corydon was the capital of Indiana Territory in 1813-1816 and of the state in 1816-1825. The old capitol building still stands. In 1863, during the American Civil War, John Hunt Morgan's raiders attacked a small Federal force here. Pop. (1930) 2,009; (1940) 1,865; (1950) 1,964.

CORYDON, town, Iowa, seat of Wayne County, 58 miles south-southeast of Des Moines. It is served by the Chicago, Rock Island and Pacific and the Chicago, Burlington and Quincy railroads. It is the shipping center for a large timothy seed producing area; and has a hatchery and an automobile battery factory. There are coal mines in the vicinity. Corydon was incorporated in 1867. Pop. (1940) 1,872; (1950) 1,858.

CORYMB, kōr'ĩmb, in botany, a simple, flat-topped or convex flower cluster with a single axis, the outermost flowers, with the longest stalks, originating farthest down on the axis, and opening first; flowers nearer the center located progressively higher, and shorter stalked; as in hawthorn.

CORYMBUS, in ancient sculpture, the wreath of ivy leaves, berries, or garlands with which vases were encircled. The term is also applied to that style of dressing the hair among the Grecian women, in which it was tied in a knot on the top of the head. The Venus de Medici represents the simplest form of this headdress.

CORYPHEA, kōr-i-fē'ná, a genus of fishes of the family Coryphaenidae, related to the mackerels. The body is elongated, compressed, and covered with small scales, and the dorsal fin extends the whole length of the back, or nearly so. The dolphin of the ancients is the *C. hippuris*. All the species, natives of the seas of warm climates, are very rapid in their motions, and very voracious. They are of brilliant colors and are objects of admiration to every voyager.

CORYPHEUS, kōr-i-fē'ūs, the leader of the chorus in the ancient Greek dramas. His functions, however, were often as wide as those of our stage manager, conductor, and ballet master. The name is now applied to the leaders of the different parts in operatic choruses, or the principal dancers in the *corps de ballet*. By extension, it is also applied to those eminent in the arts or sciences.

COS. See **Kos.**

COSEGUINA, kō-sâ-gwē'nā, volcano, Nicaragua, on a peninsula south of the Gulf of Fonseca. Cone shaped, the mountain is 3,830 feet high. A devastating eruption occurred in 1835.

COSEL. See **Kőzle**.

COSELEY, kōz'li, town, England, in Staffordshire, 8 miles northwest of Birmingham. It lies within the parliamentary boundaries of the county borough of Wolverhampton. There are iron foundries, nail, hook, chain, and screw works, grate manufactories, cement works, and brickfields. In the vicinity are extensive iron and coal mines. Pop. (1951) 34,414.

COSENZA, kō-zēn'tsä, city and commune of Italy, in Calabria, the capital of Cosenza Province and seat of an archbishop, lying on the slopes of the Sila Mountains, at the confluence of the Crati and Busento rivers. The ancient city, with its narrow, winding streets, is built on a steep hill crowned by a medieval castle, but other, partly modern, sections have spread to nearby heights. The 12th-century cathedral has the fine tomb of Isabella of Aragon. There is an academy of science and fine arts founded in the 16th-century. Ancient *Cosentia* was a leading town of the Bruttii. The Visigothic king Alaric II was supposedly buried here in the Busento River in 410. The city, which went through periods of comparative prosperity and longer ones of decline, has now added some industrial activities to its traditional ones as the agricultural trading and cultural center of the province (area 2,566 square miles; pop. 685,572). Its chief products are cereals, olive oil, fruit, and raw silk. Pop. of the commune (1951) 56,292.

COSGRAVE, William Thomas, Irish statesman: b. Dublin, 1880. After attending the schools of the Christian Brothers he entered on a business career in Dublin. He became prominent in the civic life of the city, and from 1909 till 1922 served as a member of the Dublin Corporation. An early supporter of the Sinn Féin movement, he took part in the Easter rising of 1916. After the amnesty in 1917 he was elected as a Sinn Féin to a seat in the British Parliament for Kilkenny City, and in 1918 he was re-elected for North Kilkenny. Meanwhile, in 1917 he became minister for local government in the Dail Eireann, and he continued to hold that post when the provisional government was formed in January 1922. From 1922 to 1927 he sat in the Dail Eireann as member for counties Carlow and Kilkenny, and thereafter for Cork. During August 1922 he was chairman of the provisional government, and from September to December of that year he was president of Dail Eireann. From 1922 until 1932 he served as president of the executive council of the Irish Free State, in that capacity proving himself an able administrator. With the victory of Eamon de Valera's party at the polls in 1932 he vacated office, and until his retirement from political life in 1944 he was leader of the opposition.

COSHOCTON, kō-shōk'tūn, city, Ohio, seat of Coshocton County, located on the Muskingum River 25 miles north of Zanesville. It is served by the Pennsylvania and the Wheeling

and Lake Erie railroads. Manufactures include enamelware, pottery products, and advertising novelties. Here, in 1764, Henry Bouquet (q.v.) made a treaty that ended the rebellion under Pontiac. An Indian village on the site was destroyed in 1781. The place was known as Tuscarawas until 1811, when it was made the county seat. Pop. (1950) 11,626.

COSMATI, kōz-mä'tè, name of a family of architects, sculptors, and mosaic workers who flourished in Rome from the last half of the 12th century to the beginning of the 14th. Prominent members of the family comprised Lorenzo (2d half of 12th century), Jacopo (fl. 1205-1210), Cosimo (fl. 1210-1235), Luca (fl. 1231-1235), Jacopo (fl. 1231-1293), Adeodato (fl. 1294), and Giovanni (fl. 1296-1303). They won their fame by their decorative architectural work, known as Cosmati or Roman work, distinguished by the use of mosaic and colored marbles.

COSMETICS, substances and preparations, not including soap, that are applied to the human body for cleansing, beautifying, promoting attractiveness, or altering the appearance. In the United States retail sales of such articles are approaching \$1 billion annually. The consumer is protected against dangerous substances and misrepresentations by the provisions of the Federal Food, Drug and Cosmetic Act and the regulatory powers of the Federal Trade Commission. In addition, the Council on Cosmetics of the American Medical Association reports on the quality of products and conducts public educational programs.

Cosmetic creams are used for cleansing, lubrication, or softening, and as a foundation for makeup. Modern cold creams consist chiefly of mineral oil, beeswax, and spermaceti emulsified with water, borax, and some perfume. Inclusion of synthetic waxes produces a fluffier cream. Emollient creams often contain an animal fat such as lanolin or cholesterol. Vanishing creams consist of a stearic-acid soap emulsified with glycerol and water, often supplemented with various oils and synthetic hydrophilic substances. Many special-purpose creams are also available. Bleaching creams contain ammoniated mercury, hydrogen peroxide, or sodium perborate, and may be irritating. Astringent creams contain zinc compounds or alum or related substances. Authorities are still reserving judgment as to the advisability of using creams containing estrogenic hormones. Very small amounts are present in most preparations available and it is unlikely that favorable local effects are produced on human skin.

Hand lotions most often consist of an emulsion of soap, oil, glycerin, and a gum such as mucilage of quince seed. Many other ingredients are present in specific preparations. Hand creams generally resemble vanishing creams and some hand lotions may be prepared in a similar manner with a higher percentage of water to render them liquid. Hand lotions function to absorb superficial moisture and form a thin protective coating over the skin which keeps it soft and helps prevent chapping.

Face powder consists almost exclusively of mineral products, the most important of which is talc. Other components are magnesium carbonate, kaolin, chalk, magnesium stearate, zinc stearate, zinc oxide, titanium oxide, and rice

starch. The coloring agents are usually ochers and sienna or certified organic dyes. Careful blending and adjustment of particle size are necessary to assure proper covering power, adherence, sheen, ease of spreading, and color.

Cake make-up to be used instead of or with face powder is made in the same manner as face powder with the addition of a fat or oil and an emulsifying agent. It is applied with a wet applicator.

Rouge is sold in cream, paste, and powder forms. Powder rouges are usually pressed into cakes and are essentially the same as face powder with the addition of a binder and coloring matter. Cream rouge contains pigment in a cosmetic cream base and paste rouge consists of colors, fats, and waxes.

Lipsticks contain primarily an oil, a wax, and coloring materials. Castor oil has been extensively used but fatty acid esters of glycerol and glycol are often substituted. The wax is usually beeswax, paraffin, carnauba wax, or spermaceti. Tetrabromofluorescein, called bromo acid, is the most common coloring material, but colored lakes or salts of organic dyes are also employed. The product is carefully blended for consistency, softening point, ease of application, and ability to stay for several hours. Small amounts of flavoring agents and perfumes are also added.

Nail lacquers are similar to other lacquers in that they consist chiefly of nitrocellulose dissolved in a suitable solvent such as ethyl acetate and butyl acetate. A softener or plasticizer is added to prevent brittleness and a resin to improve adhesiveness. The dyes are usually organic lakes. Nail polish removers consist of similar solvents or acetone and plasticizer. Cuticle removers are alkali solutions.

The most important hair preparations are shampoos, dyes, and permanent wave solutions. Most shampoos are soaps prepared from coconut, palm, almond, or olive oils. Recently many synthetic detergents have also been employed as soapless shampoos. Three types of hair dyes are employed. Natural vegetable dyes such as henna or walnut extract are harmless but sometimes make the hair stiff and interfere with permanent waving. Metallic dyes are also harsh and may irritate the skin. Synthetic organic dyes are now most widely used because they are easy to apply and produce pleasing results. A certain number of individuals are allergic to such substances, and the Federal Food, Drug and Cosmetic Act requires that such preparations include directions for a preliminary test. Some so-called hair tints are actually dyes. Other hair tints and rinses contain water soluble dyes which have no permanent effect on the hair. Cold wave preparations contain reducing agents, such as thioglycolate salts, which accomplish partial degradation of the hair.

Antiperspirants decrease the flow of perspiration. They usually contain aluminum compounds. Deodorants do not prevent formation of perspiration but prevent decomposition with subsequent odor. Numerous antiseptic substances, such as hexachlorophene, are used for this purpose. See also FEDERAL FOOD, DRUG AND COSMETIC ACT; PERFUMES AND PERFUMERY.

A. EARL VIVINO, M.D.,
Medical Director of Health Service, Georgetown University Medical Center.

COSMIC DUST. See **DUST.**

COSMIC RADIATION, a term which describes a high-energy, penetrating radiation which impinges upon the earth and has its origin in outer space or in the cosmos. The primary radiation is today known to consist of charged particles, mostly protons, and a few heavier nuclear particles. The term "cosmic rays" is synonymous. The word *ray* or *radiation* is used to describe streams of charged particles, in the same way that it is used in the terms "cathode rays" or "beta-rays," both of which terms refer to streams of electrons, or in the term "alpha ray," which means a stream of helium nuclei.

Cosmic radiation is detected and measured by any device or arrangement which measures ionizing radiation. There are today three main types of such detectors. First is the ionization chamber or counter. These counters, of which there are many types, including Geiger counters, proportional counters, neutron counters, scintillation counters, spark counters, crystal counters, and other varieties, all yield an electrical impulse when the particle to be detected passes through their sensitive volume. The electrical impulses can then be amplified, counted, and recorded or presented to an observer by a wide variety of electronic devices. The second type of detecting device is the cloud chamber. In this apparatus the track formed by the ionizing particle is made visible by allowing a "cloud" or a condensation of a liquid to take place along the track. This is accomplished by effecting an expansion in a saturated vapor immediately after the particle has passed. The track can be photographed, and the momentum of the particle can be measured by observing its curvature in a magnetic field. The third type of detecting device is the photographic emulsion. It has been known for a long time that ionizing particles passing through an emulsion will leave a developable track. Nuclear disintegrations and secondary-production phenomena can be studied in the emulsions as well.

Cosmic radiation was discovered in the early 1900's, when it was noted that a small amount of extremely penetrating radiation was residual after all radioactive substances had been removed or been adequately shielded from the radiation-measuring device. The conclusive experiment, performed by Victor Franz Hess of Austria, consisted of taking an ionization chamber up in a balloon flight. Hess interpreted the increased readings he obtained as he ascended by supposing that a penetrating radiation was incident upon the earth and was attenuated by atmospheric absorption, so that the intensity would be greater as the top of the atmosphere was approached. Hess further noted that there was no great difference between nighttime and daytime intensities, thus ruling out the sun as the probable source of the rays. The origin was therefore presumed to be beyond the solar system, and the adjective "cosmic" dates from this epoch.

It was at first supposed that the cosmic radiation was electromagnetic radiation, such as gamma rays or X-rays. However, the discovery of the latitude effect by J. Clay of Amsterdam in 1927 could lead only to the conclusion that the incoming rays were indeed streams of charged particles. Such charged particles would be deflected in the earth's magnetic field in a manner which would give rise to a latitude variation, whereas electromagnetic radiation would not be deflected and would not be expected to show a latitude dependence. The calculations of the trajectories

of particles of various energies were made by Fredrik Carl Mülertz Störmer in Norway and were later specifically applied to the cosmic ray problem by Abbé Georges Édouard Le Maitre of Belgium and M. S. Vallarta of Mexico. The world surveys of cosmic radiation carried out in the late 1920's and early 1930's by groups directed by Arthur H. Compton and Robert A. Millikan produced a picture of the world-wide distribution of the rays, and enabled the latitude effect to be studied in detail. Further, these surveys enabled estimates of the energy of the primary radiation to be made. Thus it was found that the primary rays had energies upwards of 2 billion electron volts. The average energies were found to be some 6 billion, and the presence of much higher energies was established. The maximum energies are not determinable by the latitude effect, but can be studied by a secondary generation process known as giant showers or Auger showers, named after Pierre Victor Auger of France. Such studies show the maximum energies in electron volts to be at least 1 followed by 16 zeros, and possibly to be 1 followed by 17 zeros. These energies per particle are very great, and today our most powerful accelerating machines can only duplicate the low-energy part of the radiation.

The complete analysis of the primary radiation has been carried out by the aid of photographic plates and counters carried to high altitudes in balloons and rockets. The results of this analysis, containing the contributions of observers from many nations, is that the primary rays are mostly protons, with a few alpha particles and a still smaller number, representing perhaps a bit under 1 per cent of the whole, of heavier nuclei. Several observers have shown that electrons are almost entirely absent in the primary radiation. Gamma rays, or electromagnetic radiation, are also not present as an important constituent of the primary radiation. Thus we may consider the primary rays to be, by numbers of entities, some 92 per cent protons, 7.5 per cent alpha particles, and about 0.5 per cent heavier nuclei. It is expected that more exact figures will be available during the next few years.

The number of such rays arriving at the top of the earth's atmosphere is around 0.34 per square centimeter per second, or about 2.2 per square inch per second, arriving in latitudes near the poles. The number at lower latitudes is substantially less. The total energy arriving at the earth in the form of cosmic radiation is approximately equal to that of starlight. No daily variation, sidereal time variation, or seasonal variation in the primary flux as large as 0.2 per cent has been found, so that the rays can be thought of as being uniformly distributed and coming equally from all points in space. Important correlations with meteorological variables such as temperature and pressure are to be expected and are found, since for example the pressure is a measure of the amount of absorbing matter in the atmosphere above the observer. The uniform intensities cited are intensities measured after corrections for temperature and pressure have been made.

Irregular variations and variations in the primary radiation which can be correlated with magnetic storms and with solar disturbances have been found. The magnetic storm effect occurs when sudden variations (storms) in the earth's magnetic field alter the amount of deflection

which the arriving radiation experiences. The correlation with solar disturbances are the result of quite complex phenomena, in which streams of charged particles are emitted from disturbed areas on the sun's surface. This study is in its infancy, and it may be presumed that the next few years will teach us many new facts about the rather complicated correlations.

The cosmic radiation, when it is incident upon the atoms and molecules in the upper atmosphere, produces a whole variety of secondary radiation, among which secondaries are found all particles known to science. A number of new particles were first discovered in the cosmic radiation. The positive electron, identical—except for the sign of its charge—with the normal negative electron, is a well-known secondary particle. So also are the various kinds of mesons or mesotrons, of which today 8 or 10 are known with some degree of certainty, and several other possible types are suspected. These particles may have charges of plus, minus, or zero in units of the electronic charge and masses which range from about 205 (μ mesons) or about 265 (π mesons) and up to higher figures, in terms of the electronic mass. In addition, V-particles are known, the masses of which are greater than that of the proton. The various mesons have radioactive decay schemes, so that, for example, a π meson decays into a μ meson, and this in turn into an ordinary electron. The full story of meson physics is exceedingly complex and is being investigated at the present time (1953). Further, secondary nuclear particles are formed, including protons, alpha particles, deuterons, neutrons, and other nuclear fragments. The neutrons enter into nuclear reactions with surrounding matter and produce such radioactive substances as radiocarbon (carbon 14), and tritium (hydrogen 3). These substances have both been detected in the atmosphere, and are both usable as dating tools, since the time which has elapsed subsequent to their formation can be measured.

It should also be said that the only radiation which reaches sea level is the secondary radiation produced at high elevations. Virtually none of the primary particles survive the passage through the atmosphere, and the mesons are the main agency by which the radiation is propagated to sea level.

What effect cosmic radiation may have in biological problems has not yet been clearly established. It has been suggested that cosmic radiation may produce mutations, or that the effects may be important biologically at high elevations. However, good control experiments are difficult to perform, and conclusive evidence is still absent. The practical applications of the radiation at present are as a tool of research. The radiation permits us to learn more about the nature and the variations of the earth's magnetic field, gives us a new tool for high altitude meteorology, and provides a means for investigating the physics of high energy radiations. Since the current high-energy machines will only reach the lowest part of the cosmic ray energy spectrum, the radiation provides us with our only source of very high energy particles and quanta. Harnessing the radiation, with the implied use for power, is evidently not a fruitful endeavor, because of the small number of cosmic ray particles.

The origin of the cosmic radiation is not at present understood. It is, however, known that cosmic ray energies are so great that they could

not originate in a nuclear process, and must therefore have their origin in a large-scale magnetic field which varies with time. Enrico Fermi proposed a mechanism in which magnetic fields in the galaxy, due to photo-ionized interstellar dust clouds moving in irregular paths, can experience inelastic collisions with particles and accelerate some of the particles to very high energies. The mechanism implies that the particles are injected at a moderate energy, and are then accelerated by the fields. Other theories have been proposed by other physicists and astronomers, but to date all except Fermi's have difficulty in accounting for the total amount of energy. Fermi's theory also recognizes the absence of much or any radiation with energy below 2 billion volts, and the absence of electrons, since the absorption effects will be high for both the electrons and the low-energy protons. The exact nature of the injection mechanism has not as yet been explained. Abbé Le Maitre has suggested that the cosmic radiation is left over from the creation of the universe. If this theory is correct, no acceleration mechanism is required. The previously mentioned absorption effects will, as before, remove the electrons and low-energy protons from the primary radiation.

SERGE A. KORFF,

Professor of Physics, New York University.

COSMOGONY, the term generally used to cover the theories concerning the origin and development of the bodies or groups of bodies found in space. Such hypotheses originally were entirely fanciful and represented only processes their originators *thought* had taken place. Since the days of Sir Isaac Newton (1642-1727), when at least some of the physical laws have become known, these hypotheses represent scientific attempts to explain the origin and evolutionary processes of the universe in accord with natural laws. While observational astronomy gives us the picture of the universe as it is today and the momentary changes that are taking place, cosmogony seeks to project this knowledge into both past and future.

The creation myths of primitive peoples are unscientific attempts at cosmogony. The account of creation in Genesis is an excellent allegorical outline, the strong evolutionary tendency of which is usually overlooked. The Hebrews undoubtedly derived it from earlier and cruder ideas prevalent in the Euphrates Valley. The early Greeks, with their vivid imaginations, had various legends describing how things in heaven and on the Earth below were created by the gods, but Thales of Miletus (604?-546 B.C.) taught the first consistent theory. An immense intellectual step was made when Aristarchus of Samos (about 270 B.C.) dared to teach that the Earth not only rotates on its axis daily but revolves annually around the Sun. This correct conception was, however, too advanced for his contemporaries, or, for that matter, for men during the next 18 centuries. Therefore, the great Greek astronomers, Hipparchus and Ptolemy (Claudius Ptolemaeus), the latter of the 2nd century A.D., and others held to the older conception of a central, fixed Earth and revolving heavens. Nevertheless, their work was the basis of modern astronomy. We should add that the eminent philosophers Plato (427?-347 B.C.) and Aristotle (384-322 B.C.) both turned to cosmological questions. Their erroneous conclusions came from too little attempt at actual ob-

servations to test their theories and from the fact that few physical laws were known in their day.

Nebular Hypothesis.—The revival of the heliocentric theory by Copernicus (1473-1543), followed by the application of the telescope to astronomy by Galileo (1564-1642), and the physical laws deduced by him and by Johannes Kepler (1571-1630), all laid the foundation for Sir Isaac Newton's unrivaled work. Once this had appeared and it was inferred that gravitation acted throughout all space, the foundation for scientific progress in cosmogony was possible. Under some form a nebular hypothesis was outlined by Emanuel Swedenborg (1688-1772); by Thomas Wright (1711-1786); and by Immanuel Kant (1724-1804). Meantime the observations of Sir William Herschel (1738-1822) had given a far better basis for speculations about nebulae, so that when Pierre Simon de Laplace (1749-1827) outlined in 1796 what is now known as the *nebular hypothesis*, he was on far safer ground than his predecessors. His hypothesis resembles Kant's, but it is believed that Laplace did not know of this earlier work.

As Laplace's hypothesis exercised such an immense influence upon all scientific thought, and as certain of his general ideas are applicable today in studies of the spiral nebulae, it is described at some length. In outline, it called for the original nebula from which the system was formed to extend beyond the orbit of the farthest planet known at that time, namely Uranus. This nebula was believed to be one vast, tenuous, hot, and slowly rotating mass, which as it contracted under the control of its own gravitation gradually cooled. Its form would become first spheroidal, then more and more elliptical as its rotation became faster. With further cooling, this rate continued to increase since the total moment of momentum remained constant. After a time, when the equatorial centrifugal acceleration would slightly surpass the gravitational attraction, a ring of nebulous matter would be left. The remainder would continue to contract, until the same thing happened again, and so on until there was a ring for each of the seven known planets. As such a ring could not have perfect uniformity, it was believed to break eventually at some point and close up on itself, forming a nebulous mass—namely an embryonic planet. This planetary mass, following the same procedure when large enough, left off rings which coalesced to form satellites, though in Saturn's case the ring survived. What was left finally contracted into the present Sun.

It will be seen that this theory at a first glance has many good aspects. It is only just, however, to repeat Laplace's words on presenting it: he advanced it "with that distrust which everything ought to inspire that is not a result of observation and calculation." The apparent good points, in view of the *then known* facts, were: (1) planets revolved about the Sun in one direction; (2) planets and Sun rotated on their axes in this same direction; (3) planets' orbits were nearly in the same plane, and nearly circular; (4) satellites revolved about their planets in the same direction the planets rotated, their orbits also being nearly circular and near the plane of the planet's equator; (5) outer planets would be larger and have more satellites. When Hermann L. F. von Helmholtz's contraction theory of the solar heat was put forth in 1854 (see SUN), the necessity for a hot initial nebula was removed,

and reason given for expecting contraction. However, the time required for contraction was only about 25 million years, which was totally inadequate for the needs of geology, as by the latter part of the 19th century it was well known that the Earth was at least many hundred million years old. By 1900, however, the reasons against the nebular hypothesis had grown to such proportions that it had to be discarded. Some of these reasons are: the orbits should be more circular and less inclined than they are; the Sun's equator should be in, not 8° from, the average plane of the orbits; the orbits of the asteroids in many cases are inconsistent with the hypothesis; retrograde satellites flatly contradict it (unless they are captured bodies); rings could not be left as postulated; even if a ring were left, it could not condense into any *one* planet; and finally, the moment of momentum of the present system is far too small.

Meantime the special case of the Earth-Moon system had received attention, especially through the work of Sir George Howard Darwin in 1878-1882. This system is the only one known where the satellite has so large a relative mass, namely about 1:81 that of its primary. According to Darwin, the two formed a single body, which rotated in five hours. This rapid rotation produced unstable equilibrium, and the Moon broke off due to the solar tidal forces. Once there were the two bodies, they revolved about their common center of gravity and rotated on their axes. Each then raised great tides upon the other, and in time these plus solar tides would result in pushing the two bodies apart, and keeping the same face of the Moon turned toward the Earth. Looking forward in time, the day would increase in length faster than the month, and would become equal at 50 or 60 of the present days. Finally the solar tides would bring the Moon back to the Earth, and they would again unite. Despite the masterly mathematical treatment of the problem, there were so many assumptions, a small change in which would modify the conclusions, that it is probably unsafe to accept the theory as representing certain events to come. Yet tidal theory is important in our system.

Planetesimal Hypothesis.—In 1900 the Laplacian hypothesis was subjected to a critical investigation by Forest Ray Moulton and Thomas Chamberlain. They concluded the hypothesis was untenable and this led to their advancing what is usually called the *planetesimal hypothesis*. This theory appeared in fairly complete form by 1905. In its original form the theory started with a spiral nebula already formed around the Sun. James Edward Keeler at Lick Observatory had but recently published his classical work on nebulae, showing that spirals existed by tens of thousands, while in no case could a Laplacian nebula be detected. We also must remember that early in the 20th century we had no idea of what spiral nebulae were, nor of their distances. It is further to be noted that, at first, the origin of the spiral itself was largely ignored, though it was suggested that the tidal effects of another star, passing near the Sun, was the cause. When the nature of spirals and their sizes were finally determined, it was seen that they were too immense to form so small a thing as the solar system.

The final form of the hypothesis is as follows: In the remote past two stars, one of which was the Sun and the other we will call *X*, approached

one another moving in orbits which were certainly hyperbolic. Just how close their passage was is uncertain, but from 5 to 10 solar radii may be about correct. The time the bodies spent near together was very brief indeed. Each body produced tides upon the other, which grew to greater heights the nearer the bodies came. Here it should be noted that presumably everything that happened to the Sun also happened to *X*, and therefore two systems should have been formed simultaneously. This apparent fact is ignored in most discussions of the subject. Finally when the two bodies were nearest, the tidal strain—plus whatever internal forces of expansion were present—was great enough to tear off bodily the upper parts of the two tidal bulges and throw these masses of hot gases out into space. The hypothesis, however, was not limited to a single ejection; more probably there were several. But for the continued gravitational attraction of *X*, all the ejected material which had less than parabolic velocity would eventually have fallen back into the Sun. However, as *X* was moving in the counterclockwise direction, all such material was given a strong component in the direction *X* was going, and would thereafter revolve about the Sun in orbits with it as a focus.

Once the two stars had separated, the region around the Sun would be filled with debris from the encounter, torn not only from it but mingled with what had come from *X*. This would be mostly in the plane defined by Sun's center and containing the orbit of *X*, though smaller quantities could also be in other planes as well. Some of the slower moving material fell back into the Sun, producing the equatorial acceleration. Much of the remainder solidified promptly into planetesimals, which from the first were more crowded in certain localities, and which varied greatly in mass. All the original orbits would be very eccentric: they were made more circular as the planetary nuclei, pushing their way through the crowd of smaller debris, picked up large quantities of it, thus increasing their own masses. The same could be said for satellite nuclei. Further, we would expect the more massive planets to have more circular orbits and also to have much lower densities, since a body of Jupiter's mass probably from the first could retain its hydrogen and other light gases, but not one of the mass of Mercury or the Moon. In these latter cases the lighter gases would diffuse away into space, leaving only the heavier ones to be incorporated into the completed volume of the bodies in question. The facts that the solar equator is inclined to the average plane of the planetary orbits, and that these latter are themselves not in one plane, are satisfactorily explained.

Tidal Hypothesis.—The *tidal hypothesis*, developed by Sir James H. Jeans and Harold Jeffreys, appeared first in 1918, and, essentially, seems a mere corollary of the planetesimal hypothesis. In this, star *X* is supposed to have drawn from the Sun a cigar-shaped filament, densest near the middle part. Jeffreys afterward substituted the hypothesis that *X* actually had a grazing collision with the Sun.

Controversial Points.—The great stumbling block, as criticism has shown, is that such an encounter as postulated in the two preceding theories gives, under the most favorable circumstances, only one tenth the angular momentum we now find possessed by the planets. This was pointed out by Henry Norris Russell, who then

As a form of mythology, the accounts given of the universe were essentially imaginative cosmogonies, attempts to describe how the universe, as it was found, came into existence. Generally speaking, the patterns adopted were borrowed by analogy from the ordinary and familiar range of human experience, particularly from craftsmanship or the process of biological birth and development. The cosmogonic myths, frequently associated in primitive religions with ritual and serving in part to rationalize the latter, were thus of a creational or of an evolutionary type.

Philosophy, which itself in its very earliest appearance undertook to transform and rationalize many such myths, provides many examples of attempts to interpret the universe in its physical aspects as parts of an inclusive, systematic account of reality as a whole. An influential tradition, still adhered to in scholastic philosophy, assigned to cosmology the study of the universe in its material, spatial, and temporal features, largely with the aid of Aristotelian conceptual distinctions, as distinguished from ontology, the study of being as such. Such treatments, however, are generally of an a priori and dialectical character and thus are incapable of progressive development.

As a scientific discipline, by contrast, cosmology involves both the appeal to observation and to theory, where the latter undertakes to systematically organize, explain, and provide clues to observational research. The observable universe is, at present, identified in Edwin Powell Hubble's phrase with the "realm of the nebulae." These are in many cases identified as vast systems of stars, comparable to our own galaxy, the system of which our Sun and its planetary system are members. As explored by our most powerful telescopes, they are found to lie at enormous distances beyond the confines of our own galaxy. The furthest distance reached so far, with the 200-inch Mount Palomar instrument, is approximately 2 billion light years, and the results of such probing disclose at once an approximately uniform, homogeneous distribution of nebulae throughout space, and a red shift in their spectra. The latter has been commonly interpreted as indicating a mutual recessional motion of nebulae from one another, and therefore supports the idea of an "expanding universe."

Among the various approaches on the level of theory are to be found the use of general relativity theory, initiated by Albert Einstein himself in 1917 with a proposal for conceiving the universe as finite, unbounded, and static. This "model" has since been abandoned along with other early attempts, whereas current relativistic schemes involve in one form or another the idea of "expanding space." However, even here, there has not emerged as yet any fully satisfactory model. Meanwhile, a number of variant suggestions have been put forward, including those of Edward Arthur Milne (1896-1950), who employed a scheme of ideas called kinematic relativity, and in another direction, a view involving the appeal to "continuous creation" put forward by Hermann Bondi, Thomas Gold, and Fred Hoyle. See also CREATION; SOLAR SYSTEM; UNIVERSE.

MILTON K. MUNITZ,

Associate Professor of Philosophy, New York University.

COSMOS, a genus of about 12 species of showy, late-flowering annual or perennial herbs, mostly native in tropical America, belonging to the sunflower family (Compositae). Closely related to *Dahlia* and *Bidens*, *Cosmos* has opposite, pinnate leaves, heads solitary or in loose clusters on long stems, about three inches wide, with pink, red, or white flowers. Commonly cultivated are the perennial black cosmos (*C. atrosanguineus*),

Cosmos (Cosmos bipinnatus)

with a red disk and dark velvety-red rays; the tall annual *C. bipinnatus*, with yellow disk and white, pink, or crimson rays; the perennial *C. diversifolius*, with yellow disk and lilac or rose rays; and the tall annual yellow cosmos (*C. sulphureus*), with heads three inches across, yellow disk, and orange or golden-yellow rays. Easily grown from seeds, these plants are widely cultivated and make fine cut flowers.

COSSA, kôs'sä, **Francesco**, Italian painter: b. Ferrara, Italy, about 1436; d. Bologna, 1478. One of the leading painters of the school of Ferrara, Cossa is first recorded working there in 1456. In 1470, after finishing the series of frescoes begun by Cosimo Tura in the great hall of the Schifanoia Palace in Ferrara, he left for Bologna, dissatisfied with the payment he had received from Duke Borso Este. He remained in Bologna until his death. In his style Cossa draws from Piero della Francesca, who had worked in Ferrara, from Andrea Mantegna and from Cosimo Tura. At Ferrara, Tura and Cossa established one of the most distinguished of the smaller schools of Italian painting, a school characterized by a taste for mannered elegance and abstraction that blended well with the atmosphere of the princely court of the Estes. Cossa's ability to fashion an individual and impressive personal style from several sources of inspiration shows clearly in the Schifanoia Palace frescoes. Of his works in Bologna the most interesting was the altarpiece painted for the Grifoni Chapel in San Petronio. Though now scattered, a number of panels from this work have been preserved; particularly impressive are the statuesque figures in the three main panels representing St. Vincent Ferrer, now in London, and St. Peter and St. John the Baptist, now in Milan.

COSSA, **Pietro**, Italian dramatic poet: b. Rome, Italy, June 20, 1830; d. Leghorn, Aug. 30, 1881. Cossa went to South America after fighting for the abortive Roman republic in 1849. On his return to Rome he wrote a series of historical plays in verse, achieving his first and greatest success with *Nero* in 1871. Among those that followed were *Messalina* (1875), *Cleopatra* (1876), *Julian the Apostate*, *The Borgias*, some of these being staged by him but published after his death. Though written with considerable dramatic sense of character and situation, the plays

were often set against backgrounds which gave the author an opportunity to express his love of Rome and his faith in liberal and anticlerical ideas. In a sense his ideas and his success are offshoots of the Risorgimento and the unification of Italy.

COSSACKS, *kos'äk* (Russ. *Kozaks, Kazaks*), wild, warlike tribes of the USSR, who in czarist times lived in frontier regions of Russia and often rebelled against the czar, yet served as czarist irregular cavalry and finally as the old regime's security police. The name of Cossack is believed to be of Tatar or Turkish origin, and has been variously translated as "free laborer," "man of the frontier," and "freebooter." The national origin of the Cossacks is obscure, but they are believed to be of mixed Russian, Ukrainian, and Tatar lineage. In personal appearance, the Cossacks closely resemble Russians, but are more slender, and have more handsome and expressive features.

As early as the 16th century, Cossack settlements arose in the Ukrainian steppe lands along the Don and Dnieper rivers. Adventurers, runaways, and the discontented of all nearby nations created these settlements to live a free life, and escape injustice. In both river basins, these Cossacks formed highly militarized states, ruled by elected generals, or so-called hetmans. They lived the wild life of frontiersmen, fighting, farming, hunting, and trading, and soon acquired a reputation as great horsemen. Every economic depression or wave of czarist repression in Russia brought more hordes of runaways into the Cossack ranks. Gradually, Cossack settlements spread into the Kuban plain of north Caucasia, the lower Volga Valley, the south Ural steppe, western Siberia, and eventually even to the Russian Far East along the Chinese frontier.

For the early czars, the unruly Cossacks were both incorrigible rebels and invaluable allies. A Cossack named Ermak Timofeev led the first Russian expedition into Siberia in 1580, laying claim to that vast territory in the name of the czar. The entire Russian conquest of Siberia was spearheaded by Cossacks. In contrast, during Russia's troubled times in the early 17th century, the Cossacks rebelled against Russia, threatened Moscow, and aided the invading Poles. In 1613, at the end of this civil war, the Cossacks first nominated Michael Romanov as czar, thus founding the Romanov dynasty which lasted until 1917. Yet soon after nominating Michael, the Cossacks rebelled against him. During the late 17th century, Cossacks repeatedly aided Russia by fighting the Turks and Poles. In 1654, Bogdan Khmel'nitski, hetman of the Dnieper Cossacks, asked Russia to annex the Ukraine, which was done. But even after annexation, the Dnieper Cossacks occasionally sided with the Turks and Poles in wars against Russia. Meanwhile, during 1667-1671, Stepan Razin, a Don Cossack, led a vast peasant and Cossack revolt against the czar in the lower Volga Valley.

In the early 18th century, the Don Cossacks rebelled against Peter I (Peter the Great), while the Dnieper Cossacks under the leadership of their hetman, Ivan Stepanovich Mazepa (or Mazeppa), joined the Swedes in war against Russia. Peter crushed both Cossack groups, but allowed them to remain freemen, on condition that they render the czar military service. Thus as serfdom became almost universal in Russia the

Cossack farmers escaped this fate. In the late 18th century, Catherine II (Catherine the Great) had to crush a huge peasant revolt in the lower Volga Valley, led by a Don Cossack, Emelian Ivanovich Pugachev. Catherine, in Russifying the Ukraine, also destroyed the Dnieper River island fortress of the Dnieper Cossacks, who thereafter were absorbed into the peaceful Ukrainian population. But in the early 19th century, the Don Cossacks fought bravely against Napoleon I's invasion of Russia.

As part of the czarist land reform, in 1869 the Cossacks were given two thirds of the land in their areas of settlement, with the other one third held by the Cossack officers or army. In return, each male Cossack had to perform 20 years' military service, either active or in the reserve, providing his own horse and arms. Thereafter, the Cossacks became firm allies of the czar, and were famed as the czar's security police, charging on horseback with their whips and sabers into revolutionary mobs. However, in 1917, the refusal of Cossacks to charge into Petrograd mobs caused the abdication of the last of the Russian czars.

After the Communist Revolution in Russia, the Don Cossacks supported the White Russians against the Reds in the Russian civil war of 1918-1920. Later, in the early 1930's, the Soviet regime had great difficulty in collectivizing the unruly, freedom-loving Cossack farmers. The Soviets feared the Cossacks, and forbade Cossack cavalry units until World War II. Then modernized Cossack cavalry was organized, and fought against the *Wehrmacht* in wooded and swampy regions. A strange climax to Cossack history is that Georgi M. Malenkov, a Ural Cossack, succeeded Joseph Stalin in 1953 as premier of the USSR.

ELLSWORTH RAYMOND,
Assistant Professor of Soviet Government and Economics, New York University.

COSSE, *ko'sä*, **Charles de**, COMTE DE BRISAC, *bré'säk*, French soldier: b. Anjou, France, c.1505; d. Paris, Dec. 31, 1563. He was at Naples during its siege in 1528, and during 1544-1546 took part in campaigns against the English and the Imperialists. He rose to the rank of grand master of artillery in 1547, and in 1550 became marshal of France.

His brother, ARTUR DE COSSÉ, COMTE DE SECONDIGNY, *sé-gôn'dé-nyé* (c.1512-1582), was also a soldier. In 1552 he helped defend Metz against Emperor Charles V, and in 1554 he distinguished himself against the Spanish in Italy. He became marshal of France in 1567. He was imprisoned for political activities during 1574-1576. In 1581 he was one of the party which journeyed to London to seek the hand of Elizabeth I for François, Duc d'Anjou.

COST ACCOUNTING. See ACCOUNTING.

COST OF LIVING. Changes in prices are of major importance to many segments of the American population. To the worker, a rise or decline in living costs has direct significance in terms of the standard of living he can achieve or maintain. As consumers' prices rise, there is almost immediate pressure for higher wages. For some 3.5 million workers, cost of living wage increases are automatic, since these people work under contracts which include escalator clauses.

To the businessman, changes in wholesale prices affect his costs and his selling prices and thus, in turn, his profits. To the investor, price changes indicate the opportunity for new investment, with all the beneficial effects that flow in terms of job opportunities and additions to our supply of goods.

Prices are at the heart of the American economic system, for it is primarily through price changes that the various parts of the system are related to each other. Actions which affect any particular price tend to have reverberations throughout the economic structure.

After the conclusion of World War II, living costs rose sharply until they reached a peak in the late summer of 1948. This rise was interrupted temporarily during 1949, when the consumers' price index declined about 4 per cent below the level which prevailed in the fall of 1948. The cost of living resumed its upward spiral in 1950 and 1951, reaching new record levels. The rate of rise abated in 1952. Nevertheless, at the end of 1952, the consumers' price index was very close to the peak level reached. In 1953 and 1954 the index recorded only minor changes.

The following tabulation shows the annual changes in the consumers' price index in the postwar period.

	Consumers' price index (1947-49 = 100)	Annual change (percentage points)
December, 1945	77.8	
December, 1946	91.9	+ 14.1
December, 1947	100.2	+ 8.3
December, 1948	103.0	+ 2.8
December, 1949	101.0	- 2.0
December, 1950	106.9	+ 5.9
December, 1951	113.1	+ 6.2
December, 1952	114.1	+ 1.0
December, 1953	114.9	+ 0.8
July, 1954	115.2	+ 0.3

This table emphasizes that there were quite substantial price rises in 1946, 1947, 1950, and 1951. By contrast, the years 1952, 1953, and 1954 were marked by a minor increase in consumers' prices.

The armament phase of the economy completed its expansional phase early in 1953 and total defense spending showed little change as the year progressed. However, the overall total of economic activity continued to expand until the spring, largely as a result of a big boom in automobile production. By July 1954, the industrial production index of the Federal Reserve Board had declined to 124 (1947-1949 = 100) from the peak of 137 reached in the spring of 1953. Some declines in business activity became evident in the early fall of 1953, although unemployment continued at a record low level for peacetime. The decline was accelerated early in 1954.

Throughout 1953, prices were relatively stable. There are three broad measures of price changes: spot market price index, wholesale price index, and consumers' price index. All three indexes have been recently modernized to take into account changes in the buying and spending habits of our population.

The spot index is composed of 22 commodities that are traded or quoted daily on spot markets and organized commodity exchanges. It covers raw materials or items close to the initial stage of the productive process. This index is compiled daily. Its component groups are food-stuffs, raw industrial products, livestock and products, metals, textiles and fibers, and fats and

oils. This index is a very sensitive indicator of prices, and thus fluctuates more widely than the wholesale price index.

The wholesale price index is composed of approximately 2,000 items and includes the sales of all commodities at the primary market level. It consists of 15 major groups and 88 subgroups. It is published weekly and monthly.

The consumers' price index measures the changes in the prices of goods and services purchased by families of city wage earners and clerical workers. It prices about 300 items. The latest change in this index took into account items that have assumed significance in living standards in recent years. Included in this category are frozen foods, television, used cars, and the direct pricing of restaurant meals. The index also reflects the costs of home maintenance and ownership. These revisions have a significant impact on long-term comparisons.

For the spot and wholesale price indexes, the peak levels were reached in February and March of 1951, after a sharp rise following the start of the Korean War. From June 1950 to the early 1951 peak, the spot index rose 51 per cent, while the comprehensive wholesale price index rose 16 per cent. These prices then declined until early in 1953. Throughout most of 1953 and 1954, they recorded only minor changes. In contrast, the consumers' price index continued to edge up slowly. As of February 1951, it was 8 per cent above June 1950; by the summer of 1954, the rise was 13 per cent. This diverse behavior was due to several factors, including the following.

The difference in coverage between the consumers' price index and the wholesale price index accounts for a significant part of the differences in their movements. The former includes services such as rents, medical care, transportation, personal care and recreation, which are not priced for the wholesale price index. These services account for 28.5 per cent of the consumers' price index. The rise in the cost of these services had lagged behind the rise in other prices during the war and postwar inflation. Although the general level of the other prices has stabilized or declined since 1951, the prices of services continued to advance. For example, rents rose almost 15 per cent between March 1951 and July 1954; transportation costs rose over 8 per cent; the cost of medical care rose almost 14 per cent.

The prices of foods and apparel declined modestly from their 1951 or 1952 peak levels as wholesale prices fell. The decline in wholesale prices of these items was significantly greater than the fall in retail prices. It is typical behavior for retail prices to lag behind—to rise less and to fall less—than wholesale prices. The increases in the prices of services more than offset the decline in the prices of commodities, with the result that the consumers' price index slowly advanced.

The prices of services went up because of the deferred inflation and the continued rise in wage rates. Rents were held down by federal controls during World War II and in the early postwar years. In the later postwar years rent controls were gradually relaxed, and in many areas they were decontrolled. Accordingly, there was a steady upward trend in rents. For example, starting in September 1953, the Office of Rent Stabilization permitted rents to be increased by 30 per cent above the level prevailing on June 30, 1947. Federal rent control was terminated

on July 31, 1953, for all except a few critical defense areas. In New York State, where rents are controlled under the state Emergency Housing Rent Control Law, rent control was relaxed early in 1953, when permissive increases of 15 per cent were approved by the legislature. Despite these developments, rents rose by less than half as much as the advance in foods and apparel since 1939.

The rise in rates for public utility services (gas, electricity, telephone, and transportation) also lagged behind other prices. During 1953 these rates were still catching up to the past inflation in costs. The prices of such services generally do not keep pace with other prices because of the regulatory time lag which characterizes regulation by the public service commissions. The continued rise in wage rates also affected the prices of services. The costs for services rendered by painters, barbers, plumbers, and electricians involve a very high proportion of labor costs. These higher wage costs affect the prices of goods as well as services.

Finally, the wholesale price index includes the prices of both raw materials and semimanufactured goods which are not covered in the consumers' price index. These prices declined sharply after early 1951, and this development partially accounts for the different actions of the two indexes.

An outstanding development in 1953 was the end of the last of price controls on March 17, six weeks before they were scheduled to die. Initially, fears were expressed by some groups that prices would run rampant. The fears proved to be unfounded, since only a few selective price rises occurred. For example, prices of cigarettes rose one cent a package following their decontrol on February 25. This price rise reflected the fact that price control had held prices down despite sharp rises in costs and the repeated requests by manufacturers for higher prices. Further, even though some sellers of gasoline sought to increase their prices after controls were lifted, they were forced to bring their prices back to the former levels because competition was so keen that the market was not able to bear such a rise. In general, the increasingly competitive nature of the markets prevented a broad price advance, although selected increases did take place.

In Canada the consumers' price index has also recently been revised. It seeks to measure the changes in the retail prices of goods and services purchased by a representative group of urban families. Included in the new index are 224 items, almost 40 per cent more than the old index contained. Such items as carbonated and alcoholic drinks, chocolate bars, fur coats, fuel oil, and phonograph records are now priced in the index. The base period has been brought up to date (1949 = 100). The peak in the Canadian index was reached in January 1952. After that time the index gradually declined. In July 1954, the consumers' price index was 1.7 per cent below the peak, but for a period of two years the index had remained stable. Within the index the following changes had occurred—foods had moved down, shelter up, clothing had remained about the same, and household operations had risen in cost. In July 1954, shelter was at its peak level, food was down nearly 8.5 per cent from its high point in the last two months of 1951, household operations were almost 1 per cent under the April

1954 maximum, and clothing was nearly 5 per cent below its peak of December 1951.

During the years between 1939 and mid-1954, the consumers' price index rose nearly 84 per cent in Canada and about 94 per cent in the United States. In Canada food had risen 123 per cent, clothing nearly 100 per cent, household operations over 76 per cent, and rent nearly 50 per cent over this span of time. Thus it may be seen that, as in the United States, the largest increase in the consumers' price index occurred in foods and the smallest rise in rents. Further, by mid-1954, in both countries the food component had declined from its peak, while shelter was currently at its highest level. However, in Canada the index had remained stable for two years because the decline in food and clothing had been sufficient to offset the rise in the other items.

JULES BACKMAN,
*Professor of Economics, School of Commerce,
Accounts, and Finance, New York University.*

COSTA, kôsh'tà, Alfonso Augusto da, Portuguese statesman: b. Ceia, Beira, Portugal, 1871; d. Paris, May 11, 1937. He received his doctor's degree at Coimbra in 1895, and in the following year became a professor of law at Lisbon. In 1900 he entered the Cortes Gerais, and in that parliamentary body led in opposing the monarchical regime. With the establishment of the Republic in 1910, he became minister of justice. In that office he took steps which led to the separation of church and state (1911). He became premier and minister of finance in 1913. After the overthrow of President Bernardino Luiz Machado in 1917, he found refuge in Paris. Later he represented Portugal at the League of Nations, and served as president of that body in 1926.

COSTA, kôs'tà, Lorenzo, Italian painter: b. Ferrara, Italy, c.1460; d. Mantua, Italy, 1535. At Ferrara he studied with Cosimo Tura, and executed his earliest work. He went to Bologna in 1480. There he came under the patronage of the Bentivoglio family, and began his connection with Francia, with whom he worked closely. Following the exiling of Giovanni Bentivoglio in 1506, he went to Mantua to paint for the Gonzagas. Illness marked his last years, and he was succeeded as court painter in 1524 by Giulio Romano. A combination of simplicity and grandeur in form, together with harmonious grouping, characterizes his work. At Bologna is much of his best work, including the *Madonna and Child with the Bentivoglio Family*, in the Bentivoglio chapel of San Giacomo Maggiore, and the *Madonna and Child with Saints Sebastian, James, Jerome, and George*, in the Baciocchi chapel of San Petronio. Other important works include *The Adoration of the Magi*, the *Madonna and Child Enthroned*, and *Saint Sebastian Pierced by Arrows*.

COSTA CABRAL, kôsh'tà kà-bräl, Antonio Bernardo da, CONDE DE THOMAR, Portuguese statesman: b. Fornos de Algodres, Beira, Portugal, May 9, 1803; d. Sept. 1, 1889. He was educated at the University of Coimbra, and began his public career as a judge in Oporto and Lisbon. In 1835 he became a legislative deputy, and in 1838 governor of Lisbon. He was minister of justice from 1839 until 1842, when he instigated

a revolution, restored the constitution of Dom Pedro IV, and became minister of the interior in name and dictator in fact. His oppressive regime was overthrown in 1846, but he regained power in 1849 and inaugurated another harsh dictatorship. He was deposed by the Duque de Saldanhar in 1851. From 1859 to 1861 he was ambassador to Brazil, and beginning in 1862 he served as president of the superior administrative court.

COSTA MESA, kŏ'stū mā'sū, village, California, in Orange County; eight miles south of Santa Ana and near the coast. It is in a dairying, farming, and citrus-fruit growing area. During the period 1940-1950 it increased its population by more than 230 per cent. Orange Coast College is at Costa Mesa. Pop. (1950) 11,844.

COSTA RICA, a country in Central or Middle America, lying in a northwest to southeast plane between the republics of Nicaragua, to the north, and Panama, to the east, and bounded by the Caribbean Sea to the northeast, and the Pacific Ocean to the west and southwest. The land area approximates 19,650 square miles. Costa Rica is the fourth smallest in size among the 20 sovereign republics of Latin America, and the 1950 census of the Americas showed it to be the smallest in terms of population (800,875; est. of Dec. 31, 1952, 869,000). The principal cities with their 1950 populations are as follows: San José, the capital, 109,963; Alajuela, 13,903; Cartago, 12,944; Heredia, 11,967; Puntarenas, 13,272; Puerto Limón, 11,310; and Liberia, 3,390. The population is largely of Spanish descent and Spanish is the official language. Cocos Island, located some 300 miles southwest of the mainland in the Pacific Ocean, is under Costa Rican sovereignty. The island is about 5 miles long and 3 miles wide, with a maximum elevation of 2,788 feet, and has two fair harbors.

The national flag is blue, white, and red (for details see FLAG). The national anthem is *Nobile patria, tu hermosa bandera* (words by José M. Zeledón, music composed by Manuel M. Gutierrez in 1821). The monetary unit of the country is the colones (U.S. \$1 = 5:60 colones officially, 6.63 on the free market in 1952).

Coat of arms.

PHYSICAL FEATURES

Geography and Climate.—Geographically, Costa Rica is a country of interesting contrasts, ranging from the high mountains of the *tierra fría*, where snow is occasionally encountered, to the lush, tropical *tierra caliente* of the Pacific and Caribbean lowlands. Two mountain groups dominate the physical as well as the human geography of the republic: the Cordillera Volcánica, to the northwest, and the Cordillera de Talamanca, to the southeast. The highest peaks, reaching over 12,000 feet in altitude, are to the south, as are the country's principal volcanoes: Poas (8,930 feet); Barba (9,534 feet); Irazú (11,260 feet); and Turrialba (10,918 feet). Between the bases of these volcanoes and the steep slopes of the main cordillera is the *meseta central*, or central plateau, a temperate highland on which is concentrated the densest rural population found anywhere in mainland Latin America. Within the central plateau are found about 75 per cent of the people of Costa Rica, and from this relatively tiny area come about 45 per cent of the nation's exports, in terms of dollar value. Here in this zone are found the principal cities of the land, including the capital, San José; Cartago, the former capital; Alajuela; Heredia; and other important towns. This temperate plateau lies between 3,000 and 5,000 feet in altitude, and is very healthful, with a mean temperature of about 68°F. During the dry season, from December to May, strong winds are a source of discomfort. Lowland zones from 3,000 feet to sea level suffer higher temperatures, with torrid climates characteristic on both seacoasts. Panamanians and coastal residents journey to the *meseta central* to escape the heat. Costa Rica, like eastern Nicaragua, Panama, and part of Colombia, has an annual rainfall of about 100 inches, though some areas are known to receive as much as 200 inches in a year. During the dry season, however, drought becomes an acute agricultural problem in certain areas. Problems of soil erosion have become serious in recent years due to exhaustive and unwise farming methods, and in some areas coffee production is down to one fifth of its former proportions.

Costa Rica has many streams. Chief river is the San Juan, which stems from Lake Nicaragua, and forms the international boundary for some of its length. The principal river lying entirely within the country is the Reventazón, also called the Parismina for part of its course. This river drains from the central plateau to a point 30 miles northwest of the port city of Limón on the Caribbean shore; the San José-Limón railroad follows its course for the most part.

POLITICAL DIVISIONS

The country is divided into seven provinces as follows:

Provinces	Area (sq. miles)	1950 Census
Alajuela	3,700	148,850
Cartago	1,000	100,725
Guanacaste	4,000	88,190
Heredia	1,100	51,760
Limón	3,600	41,360
Puntarenas	4,300	88,168
San José	1,900	281,822
Total	19,600	800,875

THE PEOPLE

Costa Rica has a population density of approximately 41 per square mile. Most of the population in Costa Rica is concentrated in the higher altitudes, and particularly in the pleasant central plateau. Like all other Latin American republics, Costa Rica is undergoing a rapid increase in population due to sustained high birth rates coupled with declining mortality traceable to improved sanitation and medical facilities, higher food production, and other factors. Even greater improvements are promised as the result of a health and sanitation agreement signed Feb. 13, 1951, between the United States and Costa Rica, which provides for a cooperative program of field work in Costa Rica.

Because of the isolation of the original colonists, and their failure to intermarry to any marked degree with such small Indian groups as were found on the isthmus, the population of Costa Rica today has a large percentage of almost completely Spanish ancestry. These are descendants of the original settlers from the Basque region and from Galicia and Aragon in Spain. Their preponderance makes Costa Rica unique among Latin American republics. For, in contrast to the pattern followed in many of the other republics, the early settlers did not intermarry widely with an aboriginal population, and Costa Rica thus avoided the mixed race problems which created economic and social difficulties in many Latin American states. The country is today more "white" than any of its sister republics of Central America. The 1950 census counted about 1,200 Indians, most of them confined on reservations. Their numbers are dwindling. An estimated 18,000 Negroes, most of them from the British West Indies, live in the Puerto Limón area, to which they were originally attracted by employment on banana plantations.

NATURAL RESOURCES

Flora and Fauna.—It is estimated that approximately one half of Costa Rica is nearly covered with virgin forests. This vegetation is at times so dense as to be impenetrable. From the coast to an elevation of 2,900 feet are tropical forests and savannas; above 6,800 feet are the regions of oaks and chaparrals, extending to 9,800 feet; and subalpine or subandean flora are characteristic in regions above this altitude and to the tops of the highest mountains. Plant life is abundant and varied, and Costa Rica boasts a greater variety of orchids than all the other Central American countries combined—more than 1,000 species. The dense forests also contain rich stands of valuable cabinet woods, such as ebony, balsa, mahogany, and cedar. Exploitation of timber resources has been somewhat retarded by lack of transportation facilities, and by the fact that the valuable trees often are found in mixed and widely scattered stands, making logging operations expensive if not impracticable.

Wildlife is abundant in Costa Rica, including jaguar, deer, puma, and many varieties of monkeys. Of avifauna there are reported some 725 species, and of Reptilia and Batrachia, over 130 species. Fish life is especially varied in the Pacific and Caribbean waters, and mainland streams contain many edible varieties. Promiscuous dynamiting of streams has caused serious fish conservation problems in recent years.

Minerals.—So far as is known, mineral resources are scanty. Gold is mined; between

\$400,000 and \$500,000 in gold bars were exported annually between 1934 and 1942. Exports have declined appreciably in recent years, however, with about \$29,000 reported for 1949. Manganese production as late as 1938 was as much as 300 metric tons annually; by 1949, however, exports had declined to \$9,000 worth of ore concentrate. In recent years, several United States oil companies have conducted explorations, but nothing worth exploiting has been discovered. As presently written, Costa Rica's mining laws do not encourage the investment of private and foreign capital for greater development of mineral resources.

ECONOMIC DEVELOPMENT

Agriculture.—In terms of national income, in 1949 the dollar value of agriculture (together with forestries and fisheries) totaled \$49 million, as compared with \$35 million for wholesale and retail trade, and \$24 million for manufacturing. Costa Rica is now, and historically has been, a land of small farmers. In 1954 some 85,000 landowners held an estimated 200,000 parcels of land, with a total cultivated area of about 1,404,000 acres. Problems of latifundia (the concentration of large holdings in the hands of a few) are not characteristic of Costa Rica. An exception exists, however, in the large parcels held by foreign-owned banana interests, though this type of latifundia appears for the most part to have benefited the economy to date. Principal exports are bananas and coffee, the former controlled almost entirely by the United Fruit Company. Cacao and abacá (Manila hemp) follow in importance. But coffee is the mainstay of the domestic economy, accounting for about one third of the total income derived from exports in 1950–1951. Between 1947 and 1951, coffee exports rose 69 per cent. Compared with the production of other Latin American republics, however, the total of Costa Rica's exports is small. Of all the coffee purchased by the United States in Latin America in 1950–1952, only 1.1 per cent came from Costa Rica. Coffee gives employment at least part of the year to one in every six persons in the country. Some 118,000 acres of land are devoted to its culture, or 50 per cent more land than any other crop uses. A large proportion of the coffee plantations are operated by small growers; of nearly 22,000 growers, only about half of them have fewer than 1,000 trees.

Costa Rica's banana industry began in 1875 through the enterprise of Minor Cooper Keith, an American engineer, who organized a company to take advantage of the new railroad he had just constructed to the Atlantic coast. The first shipments of bananas were made in 1880, and this led to the organization, in 1899, of the United Fruit Company. Production increased rapidly, reaching an all-time peak in 1913 of 11 million bunches. Atlantic coast banana plantings suffered heavily from fungus diseases in the mid-1930's, causing the company to shift operations to new plantations on the Pacific coast at Quepos and Golfito. It is anticipated that yields on these new holdings soon will exceed the all-time peak of 1913. Today, Costa Rica's production of bananas is exceeded only by that of Honduras in the Western Hemisphere. The dollar value of banana crops has recently exceeded the value of all food crops grown for domestic consumption. Cacao, important to Costa Rican economy, is the

nation's oldest cash crop. Written records as early as 1669 refer to harvests of this crop. In 1952, cacao exports brought over \$4 million. Abacá also is an important export crop, and holds promise of becoming even more valuable in years ahead.

In 1948, the National Production Council was founded to promote increases in food output by guaranteeing farm prices. In 1951, the council purchased and stored 13,000 tons of grain. By guaranteeing grain farmers' incomes, the council hoped to prevent the shift of workers and acreage to coffee production which usually results when coffee reaches price peaks. Experts agree that Costa Rica would benefit from a more varied diet of home-grown crops. Many staple products still must be imported, yet these could be grown in the country with little effort.

Costa Rica has organized a rural colonization program to stop farm-to-city migration, and to increase farm production. Semiabandoned farm land is being opened to settlement, and equipped with housing and machinery. Costa Rica contains 543,000 acres of grassland, some of which is devoted to cattle raising. Beef production and consumption are high in Costa Rica, compared with other Central American countries. The average inhabitant eats almost two thirds as much beef as the average person in the United States. Pork consumption is down, however, and chickens and eggs are too expensive for the average resident.

Industries.—Manufacturing now contributes about half as much as does agriculture to the national income. Food products lead the list, with printing and publishing second—an evidence of the nation's high literacy. Clothing and related products are third, and lumber products fourth. There are also brewing plants, shoe factories, and numerous small handicraft shops, operating to supply domestic markets exclusively. Though the waters of Costa Rica are rich in fish, the inhabitants derive little benefit from the fact. Little fresh fish is eaten in the nation, and little of the yield from tuna fishing, which centers at Puntarenas, comes back to Costa Rica.

Foreign Trade.—Costa Rica's foreign trade is principally with the United States. In the first six months of 1953, Costa Rica exported goods valued at \$21.3 million to the United States, and imported \$18.4 million. Principal exports are agricultural products and tuna fish. A shift in the type of imports from the United States has appeared in recent years, with the emphasis changing from light consumer goods to machinery and vehicles. In 1952, imports of machinery and vehicles valued at \$8.8 million were up 26 per cent from 1951, and the importance of electrical machinery alone increased 58 per cent in the same period. Conversely, metals and manufactures declined 10 per cent in the decade, as did importations in drugs and toiletries.

COMMUNICATIONS AND TRANSPORTATION

Domestic telegraph services, radio communications, and a part of the telephone system connecting San José with certain provincial cities are operated by the government through the Post Office Department. The principal telephone system, however, with headquarters at San José, is owned and managed by the National Power and Light Company. All America Cables has headquarters at San José, and branches in the port cities of Limón and Puntarenas. Approximately 30 commercial broadcasting stations operate in

the country. There are nine daily newspapers in the republic, including two English-language papers, all published in San José. Three railroad systems operate a total of 685 miles of track in the republic: the Northern Railway, from San José to Limón; the Pacific Railway, from San José to Puntarenas; and a third group of private lines owned by the United Fruit Company to serve the company's needs. Airline transportation is very important in Costa Rica, and three domestic airlines serve 24 outlying fields from the main airport at San José. International passenger traffic is almost entirely by air, though some steamship service is available from either port. The country is served by three major international air carriers: Pan-American World Airways, TACA International Airlines, and KLM (Royal Dutch Airlines). In 1951 there were 7,763 motor vehicles registered in the republic. An estimated 10,500 miles of highways served the nation, but only a fraction could be termed all-weather roads, and fewer than 62 miles were of concrete. Almost all the improved road is on the *meseta central*. The Costa Rican portion of the Inter-American Highway eventually will embrace about 313 miles, and of this total about 127 miles had been constructed in 1954. The unfinished portions present formidable engineering difficulties.

GOVERNMENT

Costa Rica is a republic, with a president elected by direct popular vote. A Constitutional Congress of 45 deputies also is elected by popular vote, and exercises legislative power. Members are elected for four years, one half of them retiring every two years. The president also is elected for four years, and the candidate receiving the largest vote in excess of 40 per cent of the total vote is considered elected. Under the Constitution of 1949, which replaced the oft-amended Constitution of 1871, all citizens over 21 may vote. Voting for president, deputies, and municipal councilors is compulsory for all males under 70 years of age. Administration of the government normally is entrusted to nine ministers, appointed by the president. Each province has a governor, also appointed by the chief executive. Governors act more as administrators of presidential orders than as independent executives. Provinces are in turn subdivided into cantons, each with a *jefe político*, or political chief, appointed by the president. Most important political acts and decisions are subject to national rather than local control, and Costa Ricans appear to take little interest in municipal government.

RELIGION, EDUCATION, AND JUSTICE

Though the predominating religion in Costa Rica is Roman Catholicism, the constitution provides for religious liberty. The nation's educational facilities have made Costa Rica the second most literate republic in Latin America (second only to Argentina). Its national university, founded in 1843, today has a faculty of 200 professors. English has been taught on the secondary level since 1944. Costa Rica often has been eulogized as the nation with more teachers than soldiers. Primary education is compulsory and free, and secondary education was declared free in 1949. In 1951, there were 1,250 primary schools with 5,301 teachers and 129,422 pupils; eight secondary schools; seven technical schools; and 59 private schools. In 1952, 16 per cent of

the national budget was expended on education.

Justice is administered by a Supreme Court, four appeal courts, and the Court of Cassation. There also are subordinate courts in the provinces, and local justices throughout the nation. Capital punishment cannot be inflicted.

HISTORY

The discovery and naming of Costa Rica generally are attributed to Christopher Columbus. In 1502, Columbus, on his last voyage to the Americas, on September 18 sailed into what is today Puerto Limón on the Caribbean coast. There he saw Indians wearing gold ornaments, causing him to write to Ferdinand V and Isabella I: "I saw in this land . . . greater evidence of gold in the first two days than in Espanola (Haiti) in four years." From his enthusiastic reports it is assumed the name "Rich Coast" or Costa Rica was born, though one authority suggests the name is a corruption of *Costa de Oreja* (Ear Coast) after the earrings worn by the natives.

Early Spanish explorers found Indians living in Costa Rica in scattered groups, and estimated their number at 25,000. The three important tribes then occupying the area were still in the stone and wooden tool stages. They had achieved considerable skill in the casting of gold into ornaments, and in pottery work and stone carving. Some efforts were made by the colonists to enslave the Indians, but these attempts largely failed and the aboriginal population began to die off. The scarcity of Indians later prevented development in Costa Rica of the *encomienda* system of semislavery which flourished in other colonies. To the sparsity of aboriginals Costa Rica may credit its strength today as a nation of small, landed proprietors.

Columbus made no effort to settle the "Rich Coast." But the new land, named Nuevo Cartago by Spain, in 1509 came under the jurisdiction of Diego de Nicuesa, governor of Castilla del Oro, in Panama. For some time thereafter the area remained largely untouched. Costa Rica's true history as a political entity dates from 1562, when a separate governor was appointed for the country. Juan Vásquez de Coronado, first governor of Costa Rica, is credited with giving the country its first real impetus, bringing colonists, livestock, and seeds from Spain. Coronado founded Cartago, which remained the seat of government until 1823, when the capital was removed to San José. By 1573 some 50 families had settled in Cartago.

The prosperity and stability which were to characterize the country's later history were absent in the early colonial period. In fact, Costa Rica was the most backward of all Spanish colonial provinces during this early period. The neglect which she suffered stemmed principally from the fact that Costa Rica had little to offer in the way of plunder and riches of the kind Spain then was harvesting from Mexico and Peru. Poverty was further exaggerated by Spain's edict that no colony might trade with any country save the motherland. Intellectual development was at a standstill, and no literature could permeate the colonies save for a few books printed in Spain. Foreigners were not permitted to enter. But the restrictions on commerce probably contributed more to the colony's misery than any other factor.

This era of darkness persisted for nearly two and a half centuries. Costa Ricans were little

touched by the currents of revolt which were running strongly in other colonies early in the 19th century. And when independence did come, Costa Rica had done nothing to win it. On hearing that Guatemala had declared freedom from Spain in September 1821, the authorities of Costa Rica, not without hesitancy, declared independence in the same year. Costa Rica achieved freedom without bloodshed.

Costa Rica and other Central American states were drawn into the short-lived Mexican Empire (1822-1823) of Agustín de Iturbide. Following the downfall of this kingdom, a federation of Central American states was formed in 1823. But the federation never succeeded, due to poor communications between its components, basic differences in their societies, and the general unpreparedness of the various peoples to live together in a democratic union. So, in 1838, Costa Rica declared her sovereignty, and ten years later the Republic of Costa Rica formally was established. Numerous attempts later were made to re-establish the federation, but none succeeded.

Costa Rica's first chief of state was Braulio Carrillo (1800-1845), under whose efficient administration the new nation saw coffee promoted, order introduced, and honor and work inculcated into a demoralized people. But the severity of his dictator-like rule was his undoing, and he was succeeded in 1842 by Francisco Morazán (1799-1842), an advocate of federation. In his zeal to push union with other Central American states, Morazán marked himself as a despot, and he was shot two months after taking office.

In 1848, Costa Rica reasserted her sovereignty, and two years later her independence was formally recognized by Spain. But the new state soon found itself faced with another threat, this time from the north in the form of the filibuster William Walker (1824-1860). Walker's filibusters invaded Guanacaste Province, but were met and defeated by Costa Rican troops. By May 1857 the adventurers had been finally repelled by combined efforts of Costa Rica, Guatemala, El Salvador, and Honduras, and Walker himself was shot. The invasion helped to solidify the Costa Rican people, however, and to build a mistrust of foreigners which was to persist for many years.

In 1871, in the administration of General Tomás Guardia (1832-1882), was introduced the constitution which, though frequently modified, remained the nation's basic law until 1949. The later years of the 19th century saw improvements in communications and marked advances in the country's educational facilities. Costa Rica had its first free elections on Nov. 7, 1889, and since then the national political life of the nation has known the power of public opinion.

In the contemporary era, the influx of United States, British, and other foreign capital has continued, assisting in the development of the banana industry and the building of railroads and other facilities. In 1919, Federico Tinoco Granados, who was not recognized by the United States, was overthrown in a popular revolt in which women took an active part. Under the administration of Ricardo Jiménez Oreamuno, which ended in 1936, the nation's financial structure was reformed, and the Pacific Railway from San José to Puntarenas was electrified. Costa Rica declared war on Japan on Dec. 8, 1941, and on Germany and Italy on Dec. 11, 1941.

In the elections of Feb. 8, 1949, Otilio Ulate

Blanco, candidate of the moderates, was elected by a narrow margin over former President Rafael Ángel Calderón Guardia; the Congress annulled the election on the ground of fraud, and President Teodoro Picado Michalski, the incumbent, refused to recognize his successor. In March 1948, a revolt under Col. José Figueres Ferrer broke out in support of Ulate, and in May the rebels set up a junta in San José. In December, Calderón Guardia led an invasion from Nicaragua which was defeated and, at the invitation of the temporary government under Figueres Ferrer, the Organization of American States conducted an investigation. On Nov. 8, 1949, Figueres Ferrer turned the government over to Ulate and a new constitution was promulgated the following day. The army, which had been completely disbanded just before Guardia's invasion of 1948, was again abolished in January 1950.

On July 26, 1953, Figueres Ferrer was elected president by a 2 to 1 margin over his conservative opponent. He cited as his ideal the middle-of-the-road socialist government of Denmark, and described the movement which brought him to power as "a revolution of the middle class." On taking office November 8, Figueres Ferrer called for gradual transfer of large, foreign-owned enterprises to "local entities." He explained that he was opposed to "permanent, large-scale foreign investments," and said that, in his view, they constitute "an economic occupation, similar in some aspects to military occupation." He referred specifically to the United Fruit Company, and said negotiations were under way to make considerable improvements in contracts with the company.

DAVID HELLYER.

COSTAIN, kōs'tān, Thomas Bertram, American editor and author: b. Brantford, Ontario, Canada, May 8, 1885. He left high school in Brantford at the age of 17 to do newspaper work. He edited *MacLean's Magazine* (Toronto) from 1910 to 1920, when he went to the United States to become associate editor of the *Saturday Evening Post*. He held that position until 1934, did motion-picture story editing during 1934–1936, and from 1939 to 1945 was an advisory editor for Doubleday, Doran and Company. He is the author of the historical novels *For My Great Folly* (1942), *Ride With Me* (1943), *The Black Rose* (1945), *The Moneyman* (1947), *High Towers* (1949), *Son of a Hundred Kings* (1950), *The Silver Chalice* (1952), and *White and the Gold; the French Regime in Canada* (1954). His projected 12-volume popular history, *The Pageant of England*, includes *The Conquerors* (1949) and *The Magnificent Century* (1951).

COSTELLO, kōs-tēl'ō, John Aloysius, Irish statesman: b. Dublin, June 20, 1891. He was educated in Dublin, and graduated from University College in 1911. He was awarded a bachelor of laws degree by Kings Inn, at London, in 1914. His public career began with his defense of Irish patriots after the 1916 uprisings. He was assistant to the attorney general of the Irish

Free State from 1922 to 1926, and served as attorney general from 1926 to 1932. During most of the years after 1932 he represented various sections of Dublin in the Dail Eireann. He headed a coalition government as prime minister from 1948 to 1951, and thus, in 1949, became the first prime minister of the Republic of Ireland. Following defeat of the Fianna Fail Party in the 1954 elections, he again headed a coalition government.

COSTER, kōs'tēr, Charles de, Belgian writer: b. Munich, Bavaria, Aug. 20, 1827; d. Ixelles, Belgium, May 7, 1879. He attended the University of Brussels. His *Légendes flamandes* (1858; Eng. tr. 1920) is a collection of old Flemish legends. His chief work, *La Légende de Thyl Ulenspiegel et de Lamme Goedzak* (1867; Eng. tr. 1943), recounts, in slightly archaic manner, the exploits of a 16th-century Fleming. Replete with earthy humor, it vividly describes Flemish life under Spanish domination. The hero is given the name and something of the character of the medieval German clown Till Eulenspiegel, and the book has been compared with François Rabelais' *Gargantua*; but despite many sources, the work is essentially original.

COSTUME. One or more garments used to clothe the human body, sometimes a special dress, historical dress in contrast to contemporary garments. Modern clothes worn in English-speaking communities, in the cities of Europe, and in South and Central America are alike in style, and are referred to as European clothes in order to distinguish them from Oriental and peasant costumes. While European clothes developed gradually from the garments of ancient Egypt, Persia, Assyria, Greece, and northern Europe, Oriental costumes changed very little until the 20th century. Peasant costumes, like religious costumes, are ancient fashions which have persisted with slight modifications. Notable examples are the costumes of Brittany and Rumania, Quaker and Mennonite dress, and the habits of nuns and monks.

Garments developed primarily from man's pleasure in decoration and ornament. Primitive man wore a lion skin as a badge of prowess, not for warmth, and people tattooed their skin as a form of decoration. The costume of primitive man often consisted of an elaborate headdress, ornaments of bone, teeth, bright metals or shells, and a mantle of fur or feathers worn over loin-cloths. Women wore short skirts of grasses or skins, and, for additional decoration, shells and beads. These ornaments were used to distinguish matron from maid. Clothes, like implements, are evidences of man's developing culture. Since European civilization began in the Mediterranean countries, we turn to the dress of Egypt, Asia Minor, and Greece for the beginnings of the history of Occidental costume.

ANCIENT MEDITERRANEAN COSTUMES

The dress of all ancient peoples, although simple in cut, was richly decorated. The function of clothes from the beginning was: (1) to proclaim the social status, profession, or wealth of the wearer; (2) to aid and protect hunters and warriors. A variety of garments were in use in any given period. Slaves wore simple garments. A king or pharaoh might wear a scanty, richly decorated garment while engaged in hunting or

EGYPT. 1-2 Persons of high rank, collar called *passum*, perfume cone on woman's head. 3—Priest or Pharaoh; headdress crown of Lower Egypt 4 Royal headdresses

fishing, then don a long elaborately draped robe, a towering headdress, and many ornaments for a banquet or ceremony.

The basic garments of all ancient peoples of the Mediterranean countries were (1) a tunic (q.v.), (2) the rectangular shawl or drape, and (3) the loin cloth for male slaves and workmen. The tunic was worn by both sexes, with or without a girdle. The rectangular shawl or drape was used by the men; the women contented themselves with a smaller cape or shawl. To these universal garments must be added (4) the short and long skirts worn only in Egypt, and (5) a leg garment worn only by Persians. The toga worn by the Romans was only a variation of the drape or shawl, being a segment of a circle instead of a rectangle. Modern dress has developed from these basic garments. Trousers or breeches are believed to have come from northern Europe rather than from Persia.

Egyptian Garments.—These were close-fitting, simple, and usually made of thin or transparent materials, white being the favorite color. Men wore a short kiltlike skirt, and women, a close-fitting tunic extending from breasts to ankles. Both sexes superimposed rectangular shawls draped like capes, and extra skirts. Egyptian skirts (c.1400–30 B.C.) had the fullness centered in the front, and highly decorative belts ending in triangular tabs. Men and women of rank always wore a round flat collar (*passim*) made of beads in elaborate patterns that extended from the base of the throat to the shoulders and breasts. The pectoral, an ornament on a chain, was worn only by people of high rank, as were the ornamental headdresses such as the hooded cobra, the miter of Osiris, etc. Both sexes wore bracelets, arm bands, ornamental girdles, and rings. It was customary to shave the head, and, in the case of males, the face. Wigs were quite generally worn. In the Empire period (c. 1580–1090 B.C.) they were tightly curled and are said to have been dyed bright colors. For ceremonious occasions men wore artificial beards. Women added fillets to their wigs, and, on the top of the head, a small cone, believed to have contained perfume. Sandals with turned-up toes were used by both men and women, although bare feet were very popular. Soldiers when in action wore protective leather bands from breast to waist, reinforced by metal disks. Children were clad like their elders or went nude.

Costumes of Asia Minor.—The ancient peoples of Chaldea, Babylon, and Assyria wore

tunics, and shawls of woolen materials in contrast to the thin clothes of the Egyptians. These garments were long; the hunting tunics of noblemen were cut in a V in front to give freedom. Men of Ninevah and Babylon, in contrast to Egyptian males, wore great black beards. Their hair was shoulder length, confined by a headband. The tall cap was reserved for royalty. The earliest masculine body garment was the long shawl, wrapped under the arms, then over the shoulder. Later, the tunic was the principal garment, on which, in course of time, a draped shawl was superimposed. Sleeves were short, the tunic ankle-length, except for fighting and hunting. Women's tunics were tight, unbelted, short-sleeved; to these might be added a short cape. Hair or wig was arranged in coils or braids. Two notable features of the costumes of the Near Eastern civilizations were (1) the heavy fringe on the shawls, and on the short tunics of warriors, and (2) heavy ornamentation. Garments were stiff with gold and jewels. Both men and women wore jeweled armlets, wide jeweled collars, and ear and finger rings.

Ancient Persian Dress.—Masculine garments were more intricate in cut but less ornate than those of Assyria. Men wore leg garments, and a coat with sleeves set into an armhole. In contrast to the short sleeves of other non-Hebrew peoples of Asia Minor, Persian men wore long sleeves. Persian trousers were long and full, but held tightly at the ankle. The materials used were linen, wool, and leather. Little is known about the dress of Persian women. They are believed to have worn long, tight-fitting tunics and scarves draped around the shoulders and over the head.

Biblical Costumes.—Hebrew costumes, after the Egyptian Exodus, display the same features as the Assyrian and Babylonian; the long tunic and the fringed shawl. Hebrew women wore ankle-length, close-fitting, short-sleeved tunics, and upon their heads tight-fitting sequin-embroidered caps covered by filmy scarves. During a late period, men wore an undertunic of linen, also a coatlike overgarment called the aba. From the Canaanites the Hebrews adopted perpendicular stripes, which became the distinguishing characteristic of their garments. Joseph's "coat of many colors" is believed to have been a garment with stripes running from the shoulders to the feet.

The foot covering of all the peoples of Asia Minor was much the same; simple sandals and elaborate ankle-high or knee-high boots. Soles and backs were leather; the front straps were crisscrossed above the instep.

ASIA MINOR. 1—Warrior of ancient Persia. 2—Assyrian king. 3—Feminine dress, Old Testament times.

CLASSIC GREECE. 1—Archer in short chiton, chlamys and boots. 2—Orator wearing himation over a chiton.

Classical Greek Costumes.—These differed greatly from those of Egypt and Asia Minor. They consisted of the chiton, the himation, and the chlamys, and were neither fitted nor shaped, but were draped upon the body. The Doric and Ionic chiton (tunic), ankle-length for women, shorter for men, was woven in a rectangular piece to the wearer's measurements. The chiton, put around the wearer, was fastened at the shoulder, the opening being usually on the right side. The masculine chiton was modified to resemble the short Asiatic tunic; it was sewed on the shoulder, and cut away under the arms to leave very short sleeves. The neck, which was cut out slightly, was bound with a band of trimming. This short garment with its three-inch belt did not reach the knees. The short chiton was also worn by Amazons and feminine athletes. In the earlier period, long chitons were worn by old and young men alike. Later, the young men adopted the short chitons, leaving their elders to wear the longer garment. The himation (cloak) was a large rectangle, like the Asiatic shawl, but unfringed. The chlamys was a smaller version of the himation, and was for the use of horsemen, travelers and foot soldiers.

Before the battle of Thermopylae (480 B.C.), Greek males wore long hair. After that event, the hair was worn short and always bound with fillets or ribbons, plus wreaths for the victors. (See *DIADEM*.) The famous hair arrangement of Grecian women, still often used in modern times, was a protruding knot arranged below the crown of the head to balance the profile of the nose, and was usually bound with ribbons. Straw hats were first worn by traveling Greek men to protect them from the sun. Elaborate helmets were adopted for fighting. Both sexes either went barefoot or wore simple sandals. For fighting and hunting there were high protective leather boots laced up in front, or a soft close-fitting foot covering resembling a sock in appearance. In infancy, children were wrapped in swaddling bands of linen, then dressed in chitons.

Roman Costumes.—Romans of both sexes wore a tunic very like the Greek chiton. The masculine garment when sleeveless and knee-length was called a tunica; when ankle-length and long-sleeved it was called a manicata. The feminine garment was the stola made of wool, linen, or silk; under it was usually worn a tunica intima of soft linen. For a wrap, Roman matrons had the palla, a long rectangular piece of woolen cloth identical with the Greek himation. Toward the end of the Roman Empire both sexes used a wide-sleeved tunic called the dalmatica, generally unbelted. In early Christian paintings

CLASSIC GREECE. 1—Doric chiton. 2—Ionic, with himation.

the female saints are usually dressed in dalmaticas.

The toga is the distinguishing Roman garment. In its early form it was the Greek himation, but, by the time of the Roman Republic (c. 500 B.C.) the garment was no longer a rectangle but had become a segment of a circle. Worn over a loin cloth, the toga was, at first, the only masculine garment of the Romans. By c. 300 B.C., it was worn over a tunica, and, by the time of the Empire (31 B.C.—476 A.D.) it was worn only on ceremonial occasions. Togas differed in color and decoration. The toga pura was made of cream wool and plain. It was worn by the leisure class and by artisans on ceremonial occasions. The toga praetexta had a purple band and was worn by officials, such as consuls, and by young boys. The toga pulla, dark gray or brown, sometimes black, was used for mourning. The toga picta, purple embroidered with gold, was worn by victorious generals, and later became the official dress of the emperor. The toga trabea came in three styles: (1) all purple, (2) purple and white, (3) purple and scarlet striped, and was worn by special personages, such as those consecrated to the gods, early kings, and by prophets or augurs. The shape of the toga changed through the centuries. It gradually enlarged until c. 100 A.D., after which it narrowed at one end. By the 7th century A.D., it had become a very long, heavily embroidered band, eight inches wide, and was wrapped over the shoulder and around the body. In this form it was worn by a Byzantine king, and later became part of the ecclesiastical vestments of the Greek Orthodox Church.

Roman men clipped their hair short, while the women wore their long hair in coils, braids, or elaborate curls. Their coiffures look like the feminine hair styles of the 20th century A.D.

ROMAN AND BARBARIAN. 1—Roman lady. 2—Toga clad citizen. 3—Teuton warrior and wife, c. 100-800 A.D.

Romans, like the Greeks and Assyrians, wore sandals and laced boots; these latter were made in black for senators and in red for patricians during the Imperial period.

BARBARIAN AND BYZANTINE INFLUENCES

Teutonic and Celtic tribes conquered by Julius Caesar wore clothes somewhat like the Romans, their main body garment being a short tunic. However, unlike the barelegged Romans, the northern European tribes wore a leg covering. Since they lived in a heavily forested region, this was possibly the first functional garment. From the 4th century A.D., when Constantine made Constantinople (Byzantium) the capital of the eastern branch of the Roman Empire, until the first Crusade c. 1100 A.D., Oriental influences in art and dress dominated Europe. The Byzantine court set the fashions for the first thousand years of the Christian era. European costume evolved from the combined influences of the Byzantine court and the northern barbarians.

Byzantine Dress.—Both men and women wore high-necked, long-sleeved tunics, belted or unbelted. A wide, short-sleeved tunic called a dalmatica, was frequently worn over the undertunic; the long, tight sleeves of the latter were revealed by the shorter sleeves of the outer garment. With the decay of the Roman Empire and the prevalence of Oriental luxury, men adopted the mode set by Roman women of wearing two ankle-length tunics. For more active pursuits, men turned to short tunics covering the knee, and hose (q.v.). In addition to the tunics both sexes wore circular or semicircular cloaks indoors and out. The difference in the appearance of Byzantine costumes from those of classic Greek and Roman came, not from a change in cut, but from the materials used. In contrast to the thin wools of Greece and Rome, Byzantine garments were made of heavy silks, and fabrics into which stripes of pure gold were woven. They were stiff with embroidery, and with gold disks and jewels that were sewed on to form all-over patterns. The women combined veils of gauzelike silk with their stiff heavy silks and embroidered wools. Court dress was gold and royal purple in color. Brilliant blues, reds, and greens combined with violet, enhanced the richness of the apparel. Shoes worn by both sexes were alike; made of fabric or soft leather of different colors, heavily ornamented with gold, jewels, and silk embroidery, they covered the foot and were heelless. Hair styles were similar to those of Rome: sometimes the women added turbans of rich silk or drew a veil over the head and shoulders.

Barbaric Dress.—Little that is authentic is known of the costumes of the barbaric tribes that poured down from northern Europe, until after the 6th and 7th centuries. From all that can be learned the special features of their costumes were: (1) short tunics worn by the men with trousers or braccæ, (2) close-fitting ankle-length or waist-length tunics, the latter combined with a skirt held about the waist by a drawstring, worn by the women, (3) short close-fitting sleeves (4) shoes of skin or leather, like Indian moccasins, or short boots akin to modern overshoes, tied about the ankle with thongs, (5) rectangular or semicircular mantles common to both sexes, (6) long hair worn by the women and braided only after marriage, (7) mustaches

and shoulder-length hair, either loose or braided, for the men, (8) helmets adorned with horns or wings, and (9) the plaids and stripes which decorated the coarse, rough materials of the garments.

The leg covering called braccæ, copied by the Roman soldiers from the Teutonic tribes, was probably a loose-fitting trouser wrapped about with thongs. The breeches supposed to have been universally worn from the fall of Rome to the end of the 13th century, were a kind of loin cloth, arranged like a baby's diaper. A leg garment called hose meaning "close-fitting" can be seen in a 9th century miniature.

MIDDLE AGES

By the time Charlemagne and the Christian bishops had created the Holy Roman Empire (800 A.D. q.v.), the integration of barbarian and Byzantine influences in dress had taken place in Europe. Kings and courtiers wore leg coverings; i.e., hose and breeches joined at knee or calf, plus a long-sleeved tunic. Women wore tunics and hose. As centuries passed, wealth and fashion demanded several tunics worn simultaneously; the overtunics had wide or short sleeves to show the under one, which was usually made of fine linen. The cut of these tunics, worn by both sexes, did not change from the 6th to the 12th century. During this period, the Christian ideal of asceticism demanded the concealment of the body, especially the distinguishing sex characteristics. For approximately six centuries there had been no change in the cut of garments; then, from about 1150 to 1450, clothes developed so rapidly in cut and variety, that this period marks the transition from classical to modern dress. In these centuries Europeans learned to tailor, and to weave different kinds of textiles, but the evolution of dress can be laid to the Crusades, to the change in armor, and to the growth of towns.

The Crusades brought enrichment and variety of new materials, artisans from the East to establish domestic weaving, and the first appearance of a fitted tunic. The upper section of the principal garment was cut to fit the body closely; at first, it was sewed or laced up under one or both arms each time it was worn. This one-piece fitted tunic was called the bliaut (c. 1150) and was followed by a more tailored garment, the cote-hardie (c. 1300). Worn over an undergarment or undertunic, the cote-hardie was long-waisted and fitted. To it a short scant skirt was attached for men, and for women a long skirt that became very full at the ankles. Cloaks were no longer draped over the shoulder in classic style, but opened in front like a modern cape. Women wore their hair in long braids or hid it under the wimple, a head drapery that encircled the face and reached to the shoulders. Elaborate headdresses did not come until after 1400 A.D.

Armor changed from a tunic of iron chains to plates of iron during the 14th century. The new, closely fitting plate armor encased the body, requiring extremely tight undergarments. Tunics were discarded for a hip-length doublet or jerkin, and tight hose that clothed both thighs and legs. We are told in the *Saint-Denis Chronicle* that it was divine wrath at the indecent costume of Frenchmen that caused their defeat in the Battle of Crecy. Except as a garment for old men and scholars, the classical tunic disap-

peared. The new military garment of iron plates brought about the first radical change in men's styles, necessitating clothes that were destined to develop into modern trousers and coats.

Community life, centering in towns rather than in isolated castle fortresses, developed the art of dress from simple to elaborate garments. Town life is essential for the display of dress. Gradually, a culture, dominated by the church and the laws of chivalry, gave way before an economy and culture based on trade and the power of individual princes. Rich merchants and powerful rulers were now enabled to proclaim their fabulous wealth and new importance in extravagant clothes of great variety of detail and ornament. During the 13th and 14th centuries fads multiplied, among them detachable sleeves of weird shapes and great length. Long trains were added to women's skirts, and both sexes decorated their clothes with heraldic devices and used fur as a trimming. Then followed parti-colored clothes, sections of which were made of different blocks of color. Hose became more important with the new short skirts worn by the men. Until the late 14th or early 15th century, hose consisted of long separate stockings with no joining at the crotch. Some hose had feet, those of ankle-length were held under the feet with a strap. Men are said to have worn drawers like a breechcloth, and the hose as it grew longer, was attached to these underdrawers by straps or was held by a garter. Shoes were of leather, velvet, or silk; soft leather boots were worn outdoors. Shoes with long pointed toes appeared in the 13th century, but the most exaggerated style did not appear until the 14th century.

The 14th century, the last period of the Middle Ages, brought the peacocklike clothes often erroneously associated with the whole epoch. Men's and women's dress became more and more differentiated. Women wore a tight body garment laced up the front, closely fitted over the hips, and with a skirt so long and full that it had to be held up by hand or tucked into a belt. This arrangement showed the rich lining of silk or fur. Over the doublet, which was laced or buttoned either in front or up the back, men wore a skirted garment. This overgarment had long exaggerated sleeves and was belted at the waist or at the thighs. Both the skirts and the sleeves were elaborately scalloped. Dignitaries and elderly men wore ankle-length robes slit to the knee to ensure ease in walking. The houpelande, the 14th century's most famous garment, was worn both indoors and out, and by both

sexes. It had a high standing collar, huge flowing sleeves, skirts that trailed on the floor, was made of costly material, and, at the height of its vogue, (c. 1390), all its edges were dagged (scalloped). This was also the period in which the long pointed shoes extended six or eight inches beyond the toes. Men and women attired in their flowing draperies glided like great birds from the Middle Ages into the Early Renaissance. Their descendants, becoming self-important and self-conscious, called for square, padded stiff lines, and the final rigidity of hoops and ruffs.

THE RENAISSANCE

By the middle of the 15th century the art of fine tailoring, and the craft of weaving intricate designs had been mastered, and medieval life dominated by the church gave way before the spirit of individualism and the power of kings and princes. Under this greater freedom, fashion in dress was permitted to satisfy the fundamental urge for (1) change, (2) contrast, (3) imitation, and (4) group conformity.

The excitement and exuberance of the Renaissance found expression in elaborate ornamentation, in richness of fabrics, in an infinite variety of costume detail, and made fashionable enormous headcoverings, great sleeves and neck ruffs. The heavy silks and velvets were strong and dark in color. The popular black velvet made a rich background for jewels, and was worn for solemn occasions—weddings and beheadings. The function of dress during the Renaissance was avowedly for decoration, self-expression, and entertainment, and so appears fantastic to modern eyes.

The Early Renaissance.—A period of exhibitionism preceded the Reformation. The differentiation between men's and women's clothes, begun with the introduction of plate armor, became more exaggerated to emphasize masculine and feminine anatomy. Men's garments, in this period, were divided into those for the upper body and those for the legs. They wore long tight hose to expose thighs and buttocks, and jerkins cut low to expose the neck. Women accentuated their breasts and hips, and bared their shoulders. Skirts were ample, and waistlines varied from those directly under the breasts to those of normal waist length. The revolutionary exposure of neck and shoulders, characteristic of the new spirit of worldliness, has continued to the present day, with the exception of a few decades in which high-necked gowns were the mode for all but court or evening dress.

RENAISSANCE. 1—Scholar's fur-lined gown over inner gown, c. 1500-1536. 2—Henry VIII of England. Sleeveless gown over skirted jerkin with puff sleeves, c. 1525-1540. 3—Fencing master in puffed trunk hose called "upper stocks," c. 1550-1600. 4—Tighter trunks called "Venetians," c. 1560-1620. 5—Peascod-bellied doublet, c. 1580-1590.

COSTUME

E VOLUTION OF MASCULINE COSTUME from the Byzantine or Early Christian tunics to the Renaissance doublet and hose. 10th century A.D.: (1) Otto III in Byzantine style long royal tunic over undertunic, (2) Nobleman in short-skirted *bliaut*, or tunic, both wear rectangular cloak covering left arm, and soft Byzantine shoes. (3) Knight wearing *surcote* or sleeveless tunic over chain armor, c. 1300-1325. (4) Beginning of tailored garments for men, a *cote-hardie* with *chaperon*, c. 1300-1350. (5) Man lacing on his hose, c. 1400. (6) Man of fashion in *houppelande*, c. 1390-1450. (7) Gentleman wearing long gown and draped *chaperon* with long tail called a *liripipe*, c. 1400-1470. (8) Young man with short-skirted doublet worn over a *pourpoint*; long hose and soft shoes of felt or velvet, c. 1470.

RENAISSANCE. 1—Italian style, c. 1500–1550. 2 English, Flemish (English headdress), c. 1525–1550. 3—Dutch, German (overgown, puff sleeves), c. 1530–1550. 4—Spanish, c. 1560–1600. 5—French peasant, c. 1525–1600.

The Mid-Renaissance.—From the discovery of the New World (1492) to the reign of Elizabeth (1558–1603), European costumes showed definite national characteristics. Courtiers, rich merchants, and their ladies imitated the fashions set by (1) the rulers of small Italian and German principalities, (2) Louis XII (1498–1515) and Francis I (1515–1547), kings of France, and (3) Henry VIII of England (1509–1547). The clothes of Italians and Spaniards, although elaborate, did not distort the human figure with exaggerated paddings, whereas the clothes worn by the Germans were overlaid with great puffs on thighs, shoulders, legs, and arms. In contrast with bombastic German dress, English, Flemish, and French costumes have an architectural quality in the simple massing of rich fabrics. In all countries heavy, rich materials, large sleeves, close body-fitting garments and heelless square-toed shoes were worn. Headcoverings were part of the costume, and were worn indoors as well as out. Only peasants went bareheaded.

The Late Renaissance.—In the Elizabethan age (1558–1603) through the reign of James I of England (1603–1625) clothes became stiffer in form, even rigid. They were held in place by wire frames under skirts and ruffs, and by large crescent-shaped rolls that distended the shoulders. Women's bodices were stiffened with iron or wooden stays, while the doublets of the men were grotesquely padded to give a pigeon-breasted effect; i.e., the peasecod bellied doublet. Influenced by Henry III of France (1574–1589), men became stiffly corseted.

Garments and Styles.—Men's clothes during the Renaissance may be described as body garments and leg garments. The body garments were: (1) a shirt with rounded neck which was visible above the doublet until ruffs were introduced (c. 1580), (2) an unstiffened doublet (later called the waistcoat) without sleeves, although separate sleeves were sometimes tied in at the armseye, (3) another doublet (often termed a jerkin) with a skirt either hip- or knee-length, also with separate sleeves tied in at the armseye; its girdle holding a dagger or sword. Men of importance wore (4) an outer gown, knee-length or longer, which was sleeveless to show the jerkin sleeve underneath. During the first half of the 16th century, all sleeves were large and puffed, but, by the end of the Elizabethan age, were small and tight at the wrists with wide cuffs. (5) The short flaring cape was made fashionable by Philip II of Spain (1556–1598) and Henry III of France. Until c. 1510 men wore hose that extended to the waist; after that, they were divided into upper and nether stocks. Upper

stocks were (1) extremely elaborate puffed trunks, or (2) full-bloused breeches that barely reached the knee, or (3) the "Venetian" i.e., tight knee-length breeches. Nether stocks consisted of hose that met the breeches or trunks. Shoes were of leather, velvet, or silk, in the first half of the century they were slashed and puffed and had exaggerated square toes. Hats were of felt, beaver, or velvet, decorated with a curled plume, or a jeweled pin.

Workmen wore a shirt, a knee-length sleeveless tunic, and tight breeches with knee-high gaiters. Servants wore a coat shaped like a cassock; it was almost ankle-length buttoned down the front and covered tight breeches and hose. Until c. 1550 knights wore metal plate armor, whereas foot soldiers wore padded garments. Shields were carried only by crossbowmen.

Women's dresses in the early Renaissance had full, long skirts, high-waisted bodices with long tight sleeves, and open necks with wide collars, or rounded necks with none. Another type of dress such as the one depicted in the tapestry "The Hunt for the Unicorn" (c. 1492), was long, tight, and tubular, with a loose girdle. From 1510–1550, women wore a visible chemise, under a tight bodice; the bodice, cut square necked, was laced at back or front. Until World War II, this style was retained in the peasant costumes of middle Europe and the Balkans. Chemise sleeves were full and wrist-length. Over them were worn, (1) wide sleeves trimmed with shoulder puffs, or (2) slashed sleeves that revealed the white sleeve of the chemise. After 1510, skirts and bodices were cut separately. From c. 1525–1550 the overskirt was either open in front or looped up to show the underdress or elaborate petticoat. While Elizabeth Tudor was still a young princess (c. 1550), the Spanish style of dress was adopted throughout Europe. The soft gathers of the skirt, held out by the farthingale and, later, by the cartwheel hoops, became rigid to match the stiffness of the bodice. Skirts were enormous and bell-shaped. The stiff, tight bodices were worn with high necks in Spain; other countries preferred low necks. After 1550, the ruff was worn with both high- or low-necked dresses. The waist line, following masculine fashion, became very long in front and pointed. Like the men, women wore falling sleeves, crescent-shaped shoulder rolls, and short, sleeveless gowns that resembled sleeveless jackets. Women's shoes were like those worn by men; heels were introduced only toward the end of the 16th century. Women also wore hose.

Women's headdresses were important and varied. Italian women wore jeweled caps or

nets, Flemish women large and small bonnets. Germans wore great structures of stiff white linen, while English women adopted caps with eartabs, or folded linen and cloth arrangements that were much less elaborate than similar German ones. Spanish women wore velvet berets over hair looped in braids, and the French discarded the earlier cone-shaped hennin with floating veil, to wear Italian caps and Flemish bonnets. Toward the end of the 16th century, the high "pompadour" hairdressing made hats impractical. During the early years of the 17th century, women wore high-crowned beaver hats in imitation of the men. These hats were sometimes perched on top of a white housecap.

Clerical costumes changed after the Reformation. Non-Catholic clergy wore the long, large-sleeved gown of the scholar, or a sleeveless, long, dark-colored gown with large white puffed undersleeves like the vestments worn by modern Episcopal bishops. Catholic clergy wore the modern chasuble, or a long gown buttoned down the front, plus a sash, like the modern cassock. The hiretta, or "square cap" of the scholar was worn by both Catholic and non-Catholic clergy.

New Costume Accessories.—The handkerchief, as a costume accessory, is first seen in Renaissance portraits, although it had been carried by Roman consuls and magistrates as an emblem of their office. Other new accessories were lace aprons and small muffs. Gloves (q.v.), worn since the 12th century by kings and nobles, were now generally worn by all who could afford them.

FROM THE RENAISSANCE TO THE FRENCH REVOLUTION

Costumes in the 17th and 18th centuries evolved from the fabulous, fantastic, nationalistic, and individualistic clothes of the Renaissance to the garments and styles worn universally by all persons of Occidental culture in the modern world. During this same period, the habits of religious groups, the robes of dignitaries (judges and clergy), the uniforms of servants, and the clothes of peasants tended to become crystallized in one or more historic or nationalistic styles.

The 17th Century.—While Spain dominated Europe and her overseas empire, her costumes—stiff, tight, elegant, and somber—controlled the world of fashion. When the power of Spain was broken, costumes changed radically, for the first time in seventy-five years. Rigid, bombastic clothes, lasting until c. 1620, were followed by loose breeches and doublets, and softer dresses. Men discarded ruffs and corsets to fight the

Thirty Years War (1618–1648), and to colonize the New World. Spain was the exception to this trend, where old fashions persisted; men continued to wear ruffs and women enormous hoops. In Europe, England, and the New World, skirts now fell in straight lines from a high waist (c. 1630–1660); then, until about 1725 these full skirts were looped up about the hips, or cut open in front to show the brilliant and rich petticoats. While Charles I reigned in England, and Cardinal Richelieu dominated France, wide collars (either square or rounded), and short sleeves were worn. Both were lace trimmed. Loops of ribbon further decorated the garments of both sexes. Women retained their lace collars until the end of the 17th century. The V-shaped point of their bodices lapped over the looped-up skirts. The wide lace collars of the men were exchanged for lace jabots, linen cravats, and ruffled shirt fronts. When ruffs were discarded, men's hair grew longer, and was worn straight or in loose curls. By 1660, however, enormous blond wigs covered their heads.

From Sweden to Austria, from Prague to The Hague, and across the fields of England, men of the 17th century fought in plumes, lace, silk, and ribbons. Their descendants, during the first seventy-five years of the 18th century did likewise; also, they danced at court, and settled a New World along the Atlantic seaboard in their satins, velvets, and brocades. Among a few religious groups plain clothes were worn, but even Oliver Cromwell is pictured in a plumed hat, and our good Cotton Mather in a periwig as richly curled and magnificent as any worn by Louis XIV. Elihu Yale's coat with its great embroidered cuffs and brocaded knee-length waistcoat shown in his full-length portrait, must have come straight from London's best tailor.

The 18th Century.—Through the first quarter of the 18th century, the principal costume features and styles of the 17th century underwent slight change. The evolution in men's costumes to tighter breeches, flaring coats and shorter vests, and in women's clothes, to the round, bell-like skirt, took place after Louis XV came of age, and while he and his beautiful mistress, Madame de Pompadour set the fashions for all the world.

Women (c. 1735) donned hoops again to give skirts a bell-shaped silhouette. Before long, hoops turned into panniers that gave great width over the hips, but tended to flatten out back and front. The dress with a V-pointed bodice was reminiscent of the Elizabethan style. Women shortened their skirts to show pretty ankles and red-heeled shoes, and discarded the long, narrow lace aprons they had worn for almost a century. Men's and women's sleeves grew tighter in the 18th century, but retained their lace ruffles until the French Revolution.

This period, from the second quarter of the 18th century to the French Revolution (1789), is often called the "rococo period." In it, the dress of both sexes attained a unity of design, a flowerlike beauty, a restraint in decorative details, and an elegance that make the clothes of the mid-18th century among the most beautiful in the history of costume. They were essentially feminine, elegant, and delicate in color. The costumes of both sexes were made of such fragile fabrics as taffeta, satin, lute-string (lustring), a glossy ribbed-weave silk, and finest muslins from India and China. They were decorated

17TH CENTURY. 1—Home dress. 2—Street dress, England and America, c. 1640–1650. 3—Fashion of 1675–1700.

with lace, exquisite embroidery, and artificial flowers. After the death of Louis XV, Marie Antoinette set the whims of fashion; the delicate feminine spirit remained, but hoops were removed and overskirts were again looped about the hips in bustle style, while men's clothes became tighter and simpler in line, though remaining rich in material.

It is illuminating to recall that from the reign of Charles I to the French Revolution the men who dressed in lace, satin, brocade, and velvet, were the ones who founded modern science, the colonies that would become the United States of America, and created the Age of Reason. Their poets, philosophers, dramatists, and scientists included Milton, Defoe, Pope, Addison, Goldsmith, Voltaire, Rousseau, Congreve, Molière, Sheridan, Galileo, Sir Isaac Newton, Benjamin Franklin; their architects were Mansard and Sir Christopher Wren; their fashion commentators Samuel Pepys and Horace Walpole, and the great artists who painted them in their costumes were Rembrandt, Vermeer, Franz Hals, Velasquez, Rubens, Van Dyck, Hogarth, Thomas Bridges, Benjamin West, Copley and Sir Joshua Reynolds.

Evolution of Masculine Garments.—The evolution of the coat took place in this age. Except for minor changes of length and decoration, it has remained essentially the same ever since. Deep tabs were sewed to the doublet, making the garment skirted. The body and skirt were cut in one piece, and worn unbuttoned from the breast down. By 1650, the coat was almost knee-length, was worn unbelted, and the sleeves were sewed into the armseye. Called a cassock, this coat bore a marked resemblance to the Persian coat as noted by John Evelyn and Samuel Pepys. By 1690, when coats were knee-length, the back skirt was slit to the waist for ease of movement. Throughout the 18th century coats were knee-length or longer, and were worn unbuttoned over the long vest. No coats had collars until the American Revolution. Lapels were first used on the uniforms of British officers (c. 1750-1770). At first coat sleeves were shortened, showing both the puff and frill of the shirt sleeve, and the turned-back cuff of the vest sleeve. Sometimes sleeves were elbow-length; more conservative men wore theirs halfway between elbow and wrist. Sleeves lengthened during the 18th century, reaching wrist-length by the American Revolution. Elaborate cuffs became smaller.

Popular with fighting men and settlers in America was the "buff jerkin." Made of leather

and sleeveless, it was as long as the ancient tunic (c. 1325 A.D.) which it somewhat resembled. For fighting (1625-1650), either a steel gorget or cuirass, or both, with a wide military sash or bandelier (cartridge or powder holder) was worn over the buff jerkin, and, on the head, a helmet, or a wide-brimmed hat with plume. During the Restoration, there was a short, loose, waist-length jerkin for artisans, and a bolero jacket with very short sleeves for courtiers. These bolero jackets and jerkins were popular with sailors; they are the so-called "pirate" coats, and were worn with very full white shirts and "slops" (baggy breeches).

Long semicircular coats for outdoor wear remained unchanged from 1630-1725, when the great coat (a larger suit coat) took its place. The great coat became double breasted about 1780.

The shirt was one of the most important masculine garments then as now. It was made full-bodied, full-sleeved and with hand ruffles until the French Revolution. George Washington was still wearing hand ruffles in 1796, as a Washington family group, painted by Savage, shows. Napoleon later revived hand ruffles, but only for formal court attire. In the last half of the 18th century, and until the middle of the 19th, the front opening of the shirt was decorated by a ruffle or double frill which showed when waistcoats were cut low. Pleated bosoms and starched fronts, with starched detachable cuffs were in fashion from 1870-1880. Modern shirt sleeves with attached cuffs are very tight when compared with the full sleeves of the 17th, 18th, and 19th centuries.

Breeches, first loose and bloused (c. 1620-1630), were held at the knee by bands and ribbons, then, by 1635, became tubular and almost ankle-length. They were edged with fringe, and worn with wide topped boots and elaborate spurs. This fighting cock gear is familiar in pictures of musketeers and cavaliers (c. 1630-1650). At the courts of Louis XIV and Charles II, petticoat breeches, lavishly ornamented with ribbons, and tubular breeches, lace-edged, were fashionable for a decade. After 1690, and throughout the 18th and early 19th centuries breeches were tight, knee-length, and fastened with buckles. With petticoat and knee breeches, men wore silk hose and red-heeled buckled shoes; tight-fitting boots took the place of loose boots for travelers and soldiers.

Characteristic Accessories.—Always associated with this age are masks for highwaymen

17TH AND 18TH CENTURIES. 1—Lord Fairfax, a general in Cromwell's army; Roundheads and Cavaliers of rank were indistinguishable in dress, c. 1630-1650. 2—Courtier in petticoat breeches; loose shirt and short doublet were favored by sailors, c. 1660-1670. 3—Beginning of the modern coat, style of Louis XIV, c. 1690-1715. 4—The great coat (1720-1760); at this period it lacked a collar. added 1780 5—Lapels mark new fashion, c. 1780-1800.

and fair maidens, and muffs and face patches for both sexes. There were tall walking sticks, dress swords for court wear, short canes, and snuff boxes for men; and for women, long gloves of pastel shades and lace mitts. From the Orient came the banyan (a loose house gown) for men, and folding fans, and parasols for ladies of fashion. Except during the reign of Charles II, women in England and America were never seen in public without a cap or headdress. Good Hollanders always wore a cap, kerchief or coif. Until the time of Queen Victoria, conservative married women wore caps, kerchiefs, hoods, bits of lace, ostrich plumes, bonnets, and turbans even while indoors. Flowers, ribbons, and plumes were worn with formal evening dresses by young unmarried women.

Children's Clothes.—In the late 18th century, children's clothes, for the first time in history, set the styles of the future. While Jean Jacques Rousseau (q.v.) seriously pleaded for a return to nature, and Marie Antoinette played at being a shepherdess, little girls escaped at last from the corseted dress of matrons into uncorseted, high-waisted, soft muslin dresses, and little boys, discarding tight vests, sailed their kites in long loose breeches, soft loose blouses, and short-waisted coats. These boys and girls became the men and women of the Directory and the Empire. Not until they were old, would tight, concealing garments return to clothe their romantic-minded grandchildren with the corsets and crinolines of the Victorian age.

The Transition Decades.—The styles of the Directory (q.v.) and the empire of Napoleon were destined to bring to adults radically different costumes from those of the four preceding centuries. The new styles did not appear, however, suddenly on July 14, 1789, or in the summer of 1795. There was a spirit of social revolt against the formal modes and manners of the 18th century a decade before the meeting of the States-General (q.v.). Almost two decades before the French Revolution, soft muslin was worn for negligee under an overdress of silk or fine calico, called a *sacque*, and later, a *levite*. Over the shoulders, and crossing the breasts, was worn a lace or net *fichu*. Under many petticoats were panniers, a hoop, or a bustle. A negligee, as defined by Max von Boehn, was "any dress not meant for great occasions, that is, any house dress, outdoor or travelling dress." In the decade 1780-1790, women first discarded the stiff 18th century bodice with its wooden and iron stays, then the hoops. Later, the *sacque* or *levite* lost its skirts, and was eventually cast aside in preparation for the Directory and Empire when women would appear in high-waisted, transparent gowns, minus petticoats. During this same decade (1780-1790), before the guillotine summoned so many great ladies of fashion, women, like their little daughters, wore softly gathered muslin skirts, wide ribbon sashes and wide-brimmed Leghorn hats. In England, rustic simplicity became chic and Abigail Adams (q.v.) wrote home in 1784 "I am a little surprised to find dress, unless on public occasions, so little regarded here . . . I have seen many ladies but not one elegant one since I came." In this transition decade hair styles changed radically, too, and Marie Antoinette cut her hair. The high powdered coiffures carrying models of ships in full sail or a coach and horses disappeared, and fashionable women turned to soft curls, or caught

their long flowing tresses together with a ribbon.

During this period men's costumes also became simpler; breeches covered the knee, and coats, following military lines, became double breasted, narrow skirted, and grew lapels. Soft collars and cravats replaced lace jabots, while broadcloth and all fine woolen materials took the place of silken fabrics for every occasion but court dress. At the meeting of the National Assembly in France, in the spring of 1789, all members of republican or radical sentiment donned suits of black in contrast to the colored silks and satins of the French nobility. Men have since worn coats of dark green, many shades of brown, and dark blue, with faun colored or white breeches, but, not since the French Revolution, except for formal dress at Napoleon's court, have masculine fashions permitted the wearing of embroidered satins and brocades such as those worn during the Renaissance, the Restoration, and the 18th century.

EMPIRES AND ROMANTICISM

The art of dress in France went with the aristocrats to the guillotine. The balance, restraint, and elegance of the 18th century costume vanished. It was chic to be as dirty and disheveled as the Paris mob until Napoleon became first consul and made cleanliness fashionable again. The years 1795-1814 (known as the Directory, Consulate, and First Empire in France, and the Federalist period in America), was a time of frankness and exhibitionism. Men emulated the males of the Early Renaissance and displayed their figures in very tight clothes. They accentuated their legs by means of skintight pantaloons of elastic knitted fabric of light color or white, and displayed their thighs by the cutting away of the skirt of the coat until it became narrow tails. Women discarded corsets and petticoats, and bared their arms, shoulders, and breasts. A fashion magazine, *La Belle Assemblée* of 1813, in describing a costume speaks of "curls on the right side for modesty veiling." Some women even dampened their clothes to further reveal the contours of the body.

Women's dresses, evolved from the pre-Revolutionary negligee, took on what was imagined to be Grecian and Roman lines. Made of muslin, and cut high-waisted, these dresses had narrow tubelike skirts which fell in small gathers from a bodice that just covered the nipples of the breasts; the sleeves were small and puffed, covering only the arm socket. Under these thin muslin dresses, fashion permitted, at first, the

EMPIRE AND ROMANTIC STYLES. 1—Top-coated gentleman, c. 1795–1815. 2—Empire dress and turban. 3—The Spencer, short, often sleeveless, jacket, c. 1810–1820.

wearing of visible pink tights, but, after Napoleon crowned himself emperor (1804) French extremes vanished, and white stockings with a single chemise, were generally adopted. Little jackets, often sleeveless, called spencers, were fashionable indoors and out. Circular capes were worn for evening; for protection and warmth, there were long coats called redingotes and pelisses. A rectangular scarf was an essential accessory; headdresses of plumes, silk turbans, or flower trimmed bonnets with sandals and heeled slippers, completed the ensemble.

During this period, men adopted for all but court dress (1) breeches that reached the calf or ankle, (2) coats with narrower and shorter skirts that grew into long narrow tails (3) shirt-sleeves without lace ruffles, shorter coat sleeves, often without cuffs (4) bobtailed coats, like Eton jackets, for boys and youths. In London, Beau Brummel set masculine fashions, insisting on fine tailoring, spotless linen, harmonious dark colors, and classic simplicity.

By 1815, the younger generation grew bored with the display of anatomy. Under the influence of Goethe, Byron, and Shelley, romantic young men yearned for a mysterious, feminine creature. Women, ever ready to please, determined to become romantic young ladies. They began by veiling their arms in long sleeves; by 1820, they had covered their breasts with lace ruching, widened their skirts at the ankle, and put on more petticoats. Only a few women, and for a short time (c. 1815–1820), wore pantalettes; we find no pictures of them at a later date with hoop skirts. Before mid-19th century, pantalettes were garments for children and teenage girls only.

"Romantic" is a term that is often applied to

the costumes worn from 1815–1840. However, the crinoline decades that follow are part of the romantic period. In the first part of the era, we note especially the transition from the tube to the bell shape in the feminine silhouette, and the tendency of men's clothes to grow looser in cut, heavier in fabric, and less decorative in detail. We also note the influence on clothes of changing feminine attitudes. Robust, healthy exercise for women became unladylike. The granddaughters of the valiant and brilliant women of the American and French revolutions went indoors to faint, to worship respectability, to live by mottoes, and to conquer by tears. Except for the works of George Sand, George Eliot, the Brontës, and Mrs. Robert Browning, feminine literature is overly sentimental. Ladies in curls, bonnets, and gloves soon found themselves on high pedestals where they could not disturb their lords and masters who were busily building commercial empires, inventing machinery, producing new means of communication, passing reform laws, and attacking many social evils. Gradually, in spite of their conservatism, men accepted, for fortune's sake, more functional clothes.

As the decades 1820–1840 advanced, waistlines in women's and men's clothes were lowered. Women's sleeves became enormous at the shoulder to balance the rapidly widening skirt. Gloves were essential, being worn indoors as well as out. Men discarded tight breeches for loose trousers, which, at first, were held under the instep by a strap. The dress coats of young men had tails, and were knee-length, whereas older, more conservative men, such as the character depicted as "Uncle Sam," retained long-tailed coats. The frock coat, however (worn for morning, business, sports, and all informal occasions), had flaring knee-length skirts and a tight, frankly feminine waist. Men of fashion wore corsets, while others tightened the waist by back lacings in the waistcoat. These waistcoats were of satin, cashmere, or cut velvet in pale tones.

From 1840–1860 women's bell skirts grew to enormous size. As in former centuries, such skirts required a small pointed waist. Once again, the feminine body was tightly laced, and, this time, neither ankles nor feet could be seen, except when ladies waltzed or danced the polka. Many ruffled petticoats and the crinoline (later the hoop) held out the wide skirts of lace, tulle, sheer muslin, or heavy silk brocade.

Except for formal evening gowns, which only the rich possessed, sleeves were long, and shoulders were covered. Shawls, wool for day and

lace for evening, were worn on all occasions. Hats were scooped bonnets, and hair was usually parted in the middle and drawn back to a knot on the neck. The difficulty of moving in the tight large dresses was commented on by Madame Carett, lady in waiting to Empress Eugénie thus: “merely to shake hands with the children or take a walk with them called for great fondness and much good will.” By mid-century, the man’s business suit consisted of plaid trousers, plaid vest, and a starched shirt. His coat reached halfway down his thighs. Gone were the high stocks of the early 19th century, as were, also, the wide velvet lapels. But he could still be romantic in evening dress, in a coat with tails and a long floating cape. However the business man might dress, the men of substance and position, such as bankers, politicians, doctors, brokers, professors and Protestant clergymen, wore the “Prince Albert” (a frock coat). This was a straight-bodied coat, with wide skirts of the same length before and behind, and familiar to Americans as the coat worn by Abraham Lincoln. Though discarded by bankers and brokers by 1905, it was still worn for all important day time functions by President Theodore Roosevelt (1901–1908), and by President William Taft (1909–1913).

ERA OF STEEL, EXUBERANCE AND ATHLETICS

The word bustle, meaning a frame worn beneath a woman’s skirt at the back, is of uncertain origin. It may well have been derived from the noun bustle, meaning agitation, fuss, commotion, haste; for such words aptly describe the era in which the bustle style characterized the feminine silhouette. The age of steel, of machinery, and of expanding international trade, stimulated by industrial expositions, created vast

new wealth for the middle classes. It was a time of ostentation when all natural forms must be concealed by ornamentation. Small houses were given grotesque steeples and turrets; indoors, marble mantles were covered with plush draperies, tables were concealed by long velvet covers, everything was fringed, and even dinner bells and wastebaskets were draped. To display the marvels of the sewing machine, women’s skirts, in bustle style, were covered with all manner of draperies and with yards of pleated ruffles, while their bodices were decorated with such factory-made products as fringe, jet, and steel passementerie, and dozens of small steel buttons. Beneath the overornamented skirt and basque, the feminine body was encased in steel ribbed corsets, and concealed by many layers of underclothes. The feminine head was covered with pounds of false hair wrought into curls, braids, and Grecian knots. Over the hair was tied a small hat laden with velvet flowers, ribbons, and feathers.

In the age of expanding communication, factories, and new inventions, only man was attaining simplicity in his attire. A functional costume was gradually developing among rich merchants and bankers. Imitated for the masses in factory-made suits, men’s clothes, like machinery, became standardized. Only in sport clothes could a young man express his individuality or love of color. The technique of tailoring the fine woollens woven in British factories, together with the subtle art of good grooming, gave prestige and distinction to men of wealth who could afford to have their clothes made to individual measure and their accessories provided by a London tailor.

The bustle style adopted by the women, like the preceding tube and bell styles, came gradually. In 1860, the Empress Eugénie appeared for the first time without a hoop. At this period Monsieur Worth, the first of the great couturiers, was designing her clothes. This innovation was followed by a decade of transition when, flattened in front, the hoop was pushed out behind. With the universal acceptance of the bustle style in 1870, the corset remained important. It tightly encased the diaphragm and ribs, pushing up the breasts, then curving out over the hips in hourglass form. This corset, with tightly laced waist, was the foundation of feminine fashions until c. 1900. Then the corset acquired a “straight-front,” and later gradually flattened the hips and buttocks for the tube style of the 20th century. The bustle style was interrupted briefly, from 1874–1878, when tight skirts were given a long train. The bustle predominated and sur-

vived until "the Gay Nineties." The bodice for the bustle skirt was a tight-fitting basque which extended below the normal waistline to overlap the skirt. Formal evening basques exposed necks and shoulders. All other dresses were long-sleeved and high-necked, and some had small standing collars.

Women skated and played croquet in long, heavy dresses, but when, in 1893, they began to ride bicycles in large numbers, and, later, to play tennis and golf, they demanded more freedom. Athletics brought the plain gored skirt and shirt-waist of the "Gibson Girl" era, but the new costume was still worn over a very tight hourglass corset. These Gibson Girl fashions were the transitional style between the bustle and the oncoming tube style of the second and third decades of the 20th century.

Fashion changes for men, from the crinoline days to the 20th century, were mainly concerned with the cut of the whiskers, hat styles, and the return of baggy, knee breeches of tweed for sport wear. Such breeches were called knickerbockers in America and were very much like the "slops" of the 17th century. Heavy beards (called "Boz" locks from Dicken's *nom de plume*), fashionable since 1842, disappeared during the bustle era. Side whiskers and mustaches remained until 1900. Polished boots, spotless linen, and a perfectly fitting coat of finest material were the essence of masculine fashion.

The new cult for sports had great influence on men's as well as on women's clothes. Young men wore bright striped blazers and flannels for tennis, cricket and informal summer outings. Older men wore knee breeches with a sack coat or belted jacket (a Norfolk) with knee-length wool stockings for bicycling, and added spats for shooting, fishing, and informal country life. Boys wore tight knee breeches or "pants" with a Norfolk jacket. Very small boys (c. 1880–1890) wore kilts. Caps with visors, especially the famous "Sherlock Holmes" cap, were worn for traveling and informal occasions. Long coats with a shoulder cape, or tweed capes of thigh length, were also popular. In the "Gay Nineties" top coats were short and flaring.

THE TWENTIETH CENTURY

The outstanding feature of 20th century costumes, especially in America, is standardization of styles of dress for women as well as for men. With the growth of democracy, standards set by mass opinion have determined the acceptance or rejection of style changes. Any costume that receives universal approval becomes fashionable, especially, since clothes have been produced in great factories for millions, rather than made by

hand, as formerly, for the individual whims of kings, queens, or public favorites. However, such celebrities still, quite frequently, initiate fashion changes. It remains to be seen whether socialistic government planning, particularly in totalitarian countries, will, in future, determine styles of dress.

In the first decade of the 20th century, changes in women's clothes carried the long full-gored skirt (minus its bustle) toward the narrow tube style, which was achieved by 1910. The tight basque was first bloused c. 1895, and became a gathered blouse, with the waistline slightly raised, by 1910. From 1914–1921 the skirt showed a few variations from the narrow tubular form, such as the "peg-top" the "hobble," and circular skirt. By 1922, the silhouette resumed the tube form, with the skirts growing ever shorter in response to feminine participation in active sports and in business, reaching knee-length during the mid-twenties. As dresses grew tighter and shorter, the waist was lowered to the hip line, and the bust was flattened. Long dresses for evening returned by 1930, with fullness from knee to ankle. The tube style persisted with slight variations in waistline and in length until c. 1937, when the normal waistline returned. Skirts of day dresses became fuller from 1937–1939, and, by 1939, evening dresses were very full, and all formal dresses showed signs of returning to the bell shape. In day clothes, high necklines returned, and shoulders were padded to balance the growing skirt fullness. With the bust no longer flattened, and a narrow, though not tightly corseted, waistline, accented by gored or gathered skirts, the tube style appeared to have completed its cycle by 1947. At this time, all restrictions in the use of material imposed by World War II regulations were lifted, and all skirts became wider and longer.

1—Evening dress, c. 1924–1927. 2—General day dress, c. 1927. 3—Evening dress, c. 1932–1937.

20TH CENTURY. 1—Business suit, c. 1900–1915. 2—Sport suit, c. 1925–1930. 3—Double-breasted, c. 1935–1950.

Up to 1949 men's styles had undergone little change since the double- or single-breasted sack suits of c. 1905–1906. Worn with matching or contrasting trousers, these became universally accepted as the business suit or day costume. Coats were given longer lapels, and lost the extremely square padded shoulders. Trousers dropped the very wide cuffs of 1905–1910, and the baggy knees of 1924. Shirt collars became softer and lower, and stiff, detachable cuffs were discarded. During World War II, in striking contrast to World War I, top ranking generals laid aside the uniform coat or tunic in warm climates; this may point a new trend in men's daytime costume. Vests were being discarded by younger men and movie stars by 1947. For all informal occasions, young men often wore colorful, sleeveless pull-over sweaters, first popularized by the Duke of Windsor when he was Edward, Prince of Wales. He also introduced waistline pleats in men's trousers. The most notable change in men's clothes between World War I and World War II, was a growing informality in dress, together with the wearing of brighter colors, first in sport sweaters and tweed coats for the country, later in business suits. This informality and change was marked by President Harry Truman's choice of a dark blue double breasted coat and matching trousers for important daytime functions which formerly would have called for the cutaway coat and striped trousers.

KATHERINE TRACY L'ENGLE,
Lecturer and Fashion Authority.

COSTUME, Academic. In the 12th and 13th centuries, when universities were taking form, they were under the jurisdiction of the church. Most of those studying were clerks in holy orders, or monks, and some were priests. They wore a habit or cloak, to which was attached a cowl or hood which could be pulled up over the head, or thrown back, according to weather conditions.

Academic costume, as such, seems to have originated at Oxford and Cambridge universities in England in the 1300's. As the British universities passed from the control of the ecclesiastics, the costumes took on brighter colors, the dress or convocation robes for the doctors, for example, being of scarlet cloth. The use of scarlet for dress use in doctors' gowns and for doctors' hoods seems to be about the only tendency toward uniformity to be found in British usage.

Academic costume has been in continuous use in the United States since colonial days. Columbia College (part of present-day Columbia University) was established by charter of King George II in 1754, under the name of King's College in the City of New York, and it transplanted to American soil many of the regulations in force at Oxford and Cambridge. The code, however, lost much of the high color so noticeable in Great Britain. The University of Pennsylvania, New York University, Trinity College at Hartford, Conn., Saint John's College at Annapolis, Md., the University of the South, and Hobart College all had codes in force before 1880. There was, however, no system discernible and few persons knew the distinguishing marks of the costumes for the various degrees. Few hoods were in use and some of them, worn by clergymen, were assumed to be articles of ecclesiastical rather than academic costume.

The idea of a well-defined system for the American colleges and universities arose about 1893 after there had become evident a decided movement toward the greater use of academic costume by senior classes, trustees, and faculties in institutions outside of those named above.

Historic academic costumes worn at Oxford University: A, c.1350, graduate of Merton College; B, 1361, earliest doctor of sacred theology, Queens College; C, 1470, Benedictine academic habit; D, 1619, regius professor of medicine at New College.

Bryn Mawr College used caps, gowns, and hoods for faculty and students in 1885, the faculty of Harvard was thus costumed for her 250th anniversary in 1886, the trustees of Yale about the same time, the seniors of Williams in 1883, the seniors of Wellesley for Tree Day in 1884, the Yale, Union, and Amherst seniors in 1891, the seniors of Harvard, Dartmouth, Syracuse University, and several others in 1892, the faculties of Brown and the University of Chicago and the seniors of the University of Vermont, Dickinson, Wesleyan, Tufts, Hampton-Sidney, Wells, Lafayette, Mount Holyoke, Elmira, Colby, and others in 1893. The movement was essentially a student movement to provide a senior badge and to improve the commencement week exercises, take the place of the "dress-suit" or "swallow-tail," and revive the tradition of a continuing and related university life. It was approved particularly by the students on account of its being uniform, thus overcoming all differences of dress. It was recognized that the gown made university functions more characteristic, interesting, and impressive to all beholders. It was discovered that the wearing of academic costume and the interest aroused by the dignity of the ceremonies resulted in a better attendance on the part of trustees, faculties, alumni, students, and friends of colleges and universities.

Since it was realized that there must be an intelligent system adaptable to all institutions if the large number of American colleges were ever to enjoy the full advantages of academic costume, an intercollegiate commission was formed in 1893 to draft a uniform code for caps, gowns, and hoods for the various degrees, so designed as to show in the hoods the sources of the degrees by use of the college colors. Col. John James McCook of the Princeton trustees, President Seth Low and Bishop Henry Codman Potter of the Columbia trustees, the Reverend Charles Ray Palmer of the Yale trustees, and Chancellor Henry Mitchell MacCracken of New York University were the most active members of this commission. Mr. Gardner C. Leonard in 1887 had designed gowns for his class at Williams College and had them made by Cotrell & Leonard of Albany, N. Y. He was greatly interested in this subject and had made extensive research into the European history of academic costume.

Following the publication of an article written by him in 1893 in *University Magazine*, he was invited to act as technical advisor to the commission. He prepared sketches, made up experimental hoods and gowns, and solved the problem of satisfactorily combining two colors in a hood lining by the adaptation of the heraldic chevron, as in the linings of the hoods of Princeton, Columbia, the University of Pennsylvania, Johns Hopkins, Cornell, and many others. The commission offered its code to all institutions of learning and it was soon officially adopted.

In 1895 the commission presented the Intercollegiate Code, and a charter was granted to Cotrell & Leonard, of Albany, N. Y., to act as sole depository for the Intercollegiate Bureau of Academic Costume, which is recognized as the authority on all matters pertaining to academic costume. Ever since then Cotrell & Leonard has maintained a library relating to academic ceremonial and a register of colors, materials, and arrangements of correct academic regalia. The bureau aims to keep from confusion the distinctive details of symbolic academic costume and to aid, without charge, all institutions with any information in its possession.

In 1932 the American Council on Education appointed a committee to determine whether a revision of the 1895 code was desirable. After correspondence and conference, departure from the existing code was suggested only in a few very minor details.

Gowns.—Photographs of the gowns used in the 1890's show them to have been rather shapeless, voluminous affairs, made for the most part by hand, but the use of modern machinery has resulted in neat, well-fitting garments which add to the dignity of the faculty, the graduates, and the commencement ceremonies.

Gowns for the bachelor's degree are to be fashioned from "worsted stuff" with semi-stiff yoke, long pleated front panels, and intricate shirring across the shoulders and back. The bachelor's gown should be worn closed and is distinguished by its long, pointed sleeves.

The master's gown has the same yoke effect but is designed to be worn open. It has a very long sleeve, oblong in shape, with an arc cut out at the bottom of the front. The oblong is closed at the base and the forearm protrudes through a notched slit near the elbow.

Gowns for the doctor's degree are also designed to be worn open, but they carry velvet panels draped around the neck and stitched down the front edges. These panels widen to five inches at the chest and are carried at this width all the way down to the hem of the garment. Three horizontal velvet bars are stitched on the upper arm of the full, round, bell-shaped sleeves. This velvet trimming may be either black or the color distinctive of the faculty to which the degree refers.

Gowns for both the master's and doctor's degrees are preferably of silk. Caps may be of serge, broadcloth or, for the doctor's outfit only, of velvet; the tassel of the doctor's cap may be of gold bullion. All materials referred to in the preceding paragraphs have been subjected to change as time has elapsed. Rayon, cotton, velveteen, and other synthetic fabrics are now being used and the further development of the manufacture of fabrics has progressed so that they are now more a matter of individual choice rather than of traditional dictation.

Hoods and Caps.—In America the hood is the most outstanding feature of all academic costume. Originally it seems to have had three uses: as a head covering, as a shoulder cape, or, when hanging from the shoulder, as a bag in which alms could be collected. The undergraduate hood is mentioned in literature as early as the 1480's. It is believed that when large wigs were worn, the cape part of the hood was cut open in front and a narrow neckband inserted. The entire garment, cape and hood proper, was allowed to fall back, producing approximately the effect which we see today. When wigs went out of fashion, the original shape was not restored, and since the hood is never used today as a head covering, it has remained in the shape of a narrow neckband connecting the two halves of the cape proper. In the earliest days of hoods at Oxford, the bachelor hoods were lined with fur. Masters and noblemen might use miniver and, during the summer, a silk lining instead of fur. Hoods for American usage were originally lined with colored silk. Changing fabric conditions have given rise to the use of artificial silk, taffeta, and rayon.

The mortarboard cap, proper for all degrees, should be worn both indoors and out upon all occasions when gowns are used. This applies to students, faculty members, and officers of the institution. The tassel is worn over the left front quarter of the cap top. The deeper part of the crown is worn to the back of the head. Caps are, of course, removed by men during prayer.

Degrees.—The shape and size of the American hood marks the college degree of the wearer, and under the system established by the Inter-collegiate Code, anyone attending an academic function in this country who is familiar with the code can readily distinguish at a glance the bachelors, masters, and doctors, and, at the same time, recognize the university or college whence each degree was obtained. This is a vast advance over the British system, because little relationship exists between the gowns and the hood-lining colors as used in the different universities and colleges there. Actually it is hard for many a Britisher to read the significance of the hoods of his own Alma Mater.

The outside of the American hood is made of black material, which should as nearly as possible match the material of the gown. The hood's outside is bordered with velvet or velveteen of the proper width to indicate the degree. The reading of the degree, and not the department in which the major work was done, governs the proper color of the border. Thus, a degree conferred as Bachelor of Science in Engineering requires the gold yellow of Science, whereas the Bachelor of Engineering degree requires the orange border of Engineering.

The shape of the bachelor's hood and the master's hood is similar, the former being three feet in overall length and the latter three and one-half feet. The doctor's hood has a base which is rounder and has an overall length of four feet. The respective widths of the velvet or velveteen borders are two inches for the bachelor's, three inches for the master's, and five inches for the doctor's hood. The colored lining of the inside of the hood is of the official color or colors of the institution conferring the degree. Some hoods, those of New York University and Chicago University, for example, have a solid color

lining. Those of some other universities or colleges, however, have what is called a chevron, or wide stripe of another color across the background color, or field. The hoods of Columbia University and Smith College exemplify the use of the chevron. Some institutions—for example, Cornell—use a double chevron, others reverse chevrons, and some use yet another device called a parti-per chevron. This device makes use of one color in the upper part of the lining and another in the lower part, as in the hoods of Washington and Jefferson College. In these ways the official colors of the college or university are combined. Since there are several hundred schools and colleges in America, various arrangements of the primary colors have had to be used and it immediately becomes apparent that the value of the Academic Code is great, if only to prevent the confusion which would soon have developed had each school gone ahead with its own color arrangements without reference to those colors which had already been registered with the Bureau by some other school.

If more than one degree is held, the gown and hood of the higher or highest degree are naturally worn. Two degrees of equal importance can be shown by dividing the velvet between the two indicative colors, but the lining can show only one conferring institution. Oxford precedent, however, is reported to direct that only a single degree from a single institution shall ever be indicated on a single garment. The American Council on Education in its report in 1935 stated that "it seems bad form to have an academic gown bear velvet stripes of various colors and the imagination dislikes to contemplate the results to which such a proposal might lead if, as often happens, the wearer held doctorates in three or more subjects."

The use of hoods by graduating classes is almost standard practice in America today and candidates who are known as eligible often don the hoods for the baccalaureate sermon or at a special ceremony at the beginning of commencement week known as "Hi Juvenes," when the names of all those who have passed the final examinations are read off. The hoods, with their aesthetic brightening of the otherwise rather somber costumes and their appeal to college spirit by the display of the college colors, thus yield their significance during the important commencement exercises.

Members of the governing body of a degree-conferring institution are entitled to wear the doctor's gown, but their hoods must represent only such degree as is actually held. In other words a trustee who holds a bachelor's degree only may wear a bachelor's hood with a doctor's gown and still be correctly attired for the convocation. A faculty member or an official of any institution who has received his degree elsewhere is entitled to wear a hood for the appropriate degree, lined with the colors of his resident school, but only during the period of his association with that school. At all ceremonies where honorary degrees are conferred, it is proper for candidates to wear the gown significant of the degree to be received. Holders of foreign degrees may wear hoods patterned on the American Code but lined with the national colors of the foreign country. Since many degrees are awarded to members of the armed services, it should be remarked here that such recipients do not wear the hood around the neck while they are in service dress. Instead,

it is folded and carried over the left forearm during the ceremonies.

A new degree, that of associate, has appeared on the graduation lists in recent years. The holder of such a degree is now recognized as a technically trained person. The curriculum for the associate is primarily a technical one and the program provides a two-year course of study in general academic and vocational subjects, including several courses usually taken in the first two years of the bachelor of arts program. In certain states, New York State for example, the Board of Regents has issued charters to some schools, with authority to issue diplomas. Some universities and colleges have followed this lead and offer the technical course and award diplomas and a distinctive hood to those students completing the two-year course. At Temple University the graduate wears a gray gown of the bachelor's type and a gray hood of the same shape as the bachelor's but without an edging of velvet. The hood is lined with the university colors in the same way as the hoods for the full degrees.

In assigning the colors to signify the respective faculties, the intercollegiate commission retained, as far as possible, historical association. For example, white for the department of arts is taken from the white fur of the Oxford hood; red, traditional color of the church, was assigned to theology; green, the color of herbs, to medicine; and golden yellow to science, etc.

Below is given the list of department of faculty colors as registered with the Intercollegiate Bureau of Academic Costume.

Agriculture	Maize
Arts, Letters, Humanities	White
Business Administration, Commercial Science	Drab
Dentistry	Lilac
Economics	Copper
Education, Pedagogy	Light Blue
Engineering	Orange
Fine Arts, Architecture	Brown
Forestry	Russet
Humanics	Dark Crimson
Laws	Purple
Library Science	Lemon
Medicine	Green
Music	Pink
Nursing	Apricot
Oratory	Silver Gray
Pharmacy	Olive
Philanthropy	Rose
Philosophy	Blue
Physical Education	Sage Green
Public Health	Salmon
Science	Golden Yellow
Social Service	Citron
Surgical Chiropody	Nile Green
Theology and Divinity	Scarlet
Veterinary Science	Gray

The codes for academic dress in Canada differ with each university. For example, King's College, in Halifax, Nova Scotia, established in 1802, uses the same code as Oxford University, England. The University of Ottawa follows to some extent French custom in conferring the degree of licentiate instead of master. Hoods are used here to denote the degrees despite the fact that French universities do not use them, but scarves instead. Laval University, on the other hand, uses scarves.

The universities of India follow individual codes but use the hood shapes of the universities of Great Britain. The University of Ceylon does not, however, use hoods. The University of Hong Kong has a code and uses gray silk for some and scarlet cloth for other hoods to denote academic degrees.

Official Colors.—The official colors for the hood linings of some of the leading institutions of the United States are as follows:

Amherst	Purple, white chevron
Boston University	Scarlet, white chevron
Brown	Brown, cardinal chevron
Bryn Mawr	Maize, white chevron
Catholic University	Papal yellow, white zone
Colgate	Maroon
College of the City of New York	Lavender
Columbia	Light blue, white chevron
Cornell	Cornelian red, two white chevrons
Dartmouth	Green
Fordham	Maroon
Georgetown	Gray, blue chevron
Harvard	Crimson
Holy Cross	Purple
Johns Hopkins	Black, gold chevron
Leland Stanford Jr.	Cardinal
Massachusetts Institute of Technology	Bright red, silver gray chevron
Miami University, Ohio	Bright red, white chevron
New York	Violet
Northwestern	Purple, gold yellow chevron
Ohio State	Scarlet, silver gray chevron
Princeton	Orange, black chevron
Radcliffe	Crimson, white chevron
Smith	White, gold chevron
Syracuse	Orange
Temple	White, cardinal red chevron
University of Alabama	Oxford crimson, white chevron
University of California	Gold, blue chevron
University of Chicago	Maroon
University of Illinois	Navy blue, two orange chevrons
University of Kansas	Dark blue, red chevron
University of Kentucky	Blue, white chevron
University of Maine	Light blue
University of Michigan	Maize, azure blue chevron
University of Minnesota	Old gold, maroon chevron
University of North Carolina	Light blue, two white chevrons
University of Oregon	Lemon yellow, dark green chevron
University of Pennsylvania	Red, blue chevron
University of Pittsburgh	Navy blue, gold yellow chevron
University of Rochester	Dandelion yellow
University of Southern California	Gold, cardinal chevron
University of Texas	White above orange, parti-per chevron
University of Washington	Purple above gold, parti-per chevron
University of Wisconsin	Bright red
Vassar	Rose, gray chevron
Wellesley	Dark blue
Williams	Royal purple
Yale	Blue

COSTUME, Ecclesiastical. Hebrew.—The vestments of the priestly religion of ancient Israel were nearly all post-exilic in form if not in origin. The ephod and breastplate used originally to divine the Lord's will in some particular matter came to be restricted to use by the high priest. The detailed descriptions of each in Exodus 28 and in *The Antiquities of the Jews*, book 3, by Flavius Josephus (37-?100), represent the forms used or developed from the time of Ezra (5th century B.C.) on. Maimonides' *Mishnah Torah*, chapter 8, has some detailed

notes on texture, but this comes even later (12th century A.D.) as a statement.

The vestments existing in the year 70 A.D. may be described as follows: There was a linen breech cloth (translated as breeches in the King James Version), dictated by the Hebrew dislike of nudity. A coat of fine linen was cut long and close-sleeved. There was also a girdle of linen about 3.5 inches wide and (supposedly) about 58 feet in length. This was wound round and round the body, and finally tied over the breast, with the ends being permitted to hang down to the feet. The girdle was covered with elaborate needlework of many colors. The priestly headgear was a padded turban covered with white linen. The high priest had, in addition, an inscribed golden pate bound on to the turban by blue ribbon. The robe of the ephod was a blue sleeveless tabard worn by the high priest over the garments mentioned above. The stipulation of alternate golden bells and blue, purple, or scarlet pomegranates to be hung from its hem would indicate some secular origin, since in classic days the reproduction of pomegranates would have been regarded as a violation of the Second Commandment. The ephod, as described by Josephus, was a multicolored sleeved tabard somewhat shorter than the blue robe just described and was worn over it; it was held in place by an attached richly worked girdle. It has no apparent relationship with the linen ephod referred to in I Samuel 2:18 and elsewhere in the older books of the Bible. There is one strange reference to a rich ephod which became an object of idolatry in Gideon's time, but in general the ephod was some sort of linen garment once common to the prophets and all the clergy irrespective of rank, and was associated with divining rather than sacrifice. The breastplate (in Hebrew the word means a bag, or covering, on the chest) was a rectangular piece of material identical with the cloth of the ephod, doubled to preserve its ancient bag-like character. After folding, it was about nine inches square. Four rows of three precious stones each were set in gold upon it, and each stone was inscribed with the name of one of the twelve tribes. The breastplate was held in position at the top by two braided chains of gold running from the upper corners to the shoulder clasps of the ephod, and by two blue cords which ran from the lower corners to the girdle at either side.

Modern synagogue practice has abandoned all of the vestments associated exclusively with temple worship, but has preserved the external coverings required of the men of Israel. The prayer shawl (*tallit*) is a white scarf having on its ends the prescribed bands and fringes originally ordered to be worn on the mantle. (Numbers 15:38.) The cap (*yarmelka*) is generally of black, but varies much in shape. The phylacteries (*t'fillin*) are small leather cases bound by leather thongs to the forehead and to the right arm and hand. They contain small strips of parchment inscribed with the Summary of the Moral Law (Deuteronomy 6:8). The fringe (*tsitsit*) is an open-sided cloth scapular of waist length, held in place by strings tied at the sides; on the four bottom corners are clusters of ceremonial fringe much like those of the *tallit*. The *tsitsit* is worn under the shirt, but the fringes, although meant to hang free, are often gathered up into four pockets above them. The grave-clothes (*kittel*) are white tunics worn by the

married in special ceremonies on Rosh Hashanah and Yom Kippur, and are used at burial. (It should not be assumed that all or, indeed, any of the foregoing vestments are in universal use; dress customs will vary with individual congregations.)

Christian.—The early church was not interested in vestments. Clement of Alexandria (c.150–c.215) mentions a preference for white, but this meant only that Christians should wear ordinary clothing of that color when in church. The Fourth Council of Carthage (c.400) mentions an alb in a purely ecclesiastical sense, but as late as 430 Pope Celestine I wrote a scathing letter to the bishops of Narbonne and Vienne condemning their preoccupation with dress. He wrote, "We should be distinguished from the common people, or from all others, by our learning, not by our dress; by our habit of life, not by our clothing; by the purity of our minds, not by the cut of our garments."

Gregory I (540?–604) mentions the dalmatic maniple and pallium as being in common use in his church. The Fourth Council of Toledo (633) lists stole, chasuble, alb, ring, and staff as vestments within the accepted sense, although it is clear that they were not as yet exclusively ecclesiastical in use. By 840, Walfrid Strabo was interested in proving that the number of the vestments used was the same as that of the ancient Jewish priesthood; and by 850 Rabanus Maurus, the archbishop of Mainz, finds not only the number but the vestments themselves to be more or less parallel in intention and usage. Between the 9th and the 13th centuries the number of vestments used in the West was exactly doubled.

It is necessary to bear these facts in mind when examining the list of vestments which have come to be used in the Christian churches, since the sincere efforts of pious writers from the 13th century to the late 19th century have succeeded in persuading most people that symbolism rather than utility dictated the design of vestments. Gulielmus Durandus' *Rationale Divinorum Officiorum*, written in about 1286, should be noted as a classic example of this pious approach; his section on the ecclesiastical use of ostrich eggs and the symbolism involved is the medieval mind at its most fanciful.

Many vestments are used by both East and West. The alb (*sticharion*), the white tunic of ordinary Greek and Roman people, came to be the standard undergarment of the clergy. The two vertical stripes with which it was decorated, known as *clavi*, eventually were placed on an overgarment. Colored albs are common in the Eastern Church and were in wide use in the West up to the 16th century.

The dalmatic (*sakkos*), or Dalmatian tunic, was a wide-sleeved garment which went on over the head, and which when laid out flat had the shape of the letter T. (In the reign of Commodus, 180–192 A.D., it was regarded as clothing too foreign for a Roman emperor to wear in public.) The *clavi* or vertical stripes of the alb were transferred to it in the next century with the addition of stripes on the sleeves. By the 4th century a rich dalmatic became the sign of imperial favor; thus, the bishops of the two capitals might wear it as a special grant. The Roman deacons wore it as a distinctive dress. By the 7th century, the garment fell out of popular use and was kept only by the clergy. In the West

it came to be the characteristic dress of deacons. In the East since the fall of Constantinople (1453) the *sakkos* has been worn by all metropolitans and since the 18th century by all bishops. In both East and West the garment has always been the coronation dress of the emperors and kings.

The chasuble (*phelonion*) was developed from a peasant form of poncho known in Greece as early as 500 B.C. This garment, variously known as *paenula*, *casula*, or *planeta*, came, in a richer form, to be the outdoor dress of the official and noble classes. As such it was used by bishops and priests, but not until after the 8th century was it used exclusively (with the exception of sovereigns) by the clergy. In the East, the original form of a half circle, joined up the front with an aperture for the head, has been reduced in depth so that the forearms may move freely (the same was true in the West in the 11th century). In the West, the original shape was altered by shortening the sides rather than the front. In the Renaissance period the sides disappeared entirely and a tabard shape was all which was left. After the Gothic revival of the 1830's, the older forms again became popular.

The pallium (*omophorion*) was originally a classic-period Greek shawl called himation. It was about 18 feet long and 6 feet wide, and was a complete covering, being draped over the left arm, across the back of the body, under the right arm, and across the front of the body to the left shoulder again. By the 2d century A.D. it had become the characteristic dress of teachers and scholars. By the middle of the 4th century it had ceased to be an article of common dress and was used only by the official classes; at this period it was worn folded into a long, narrow strip. When worn over the chasuble it was carried over, rather than under, the right arm. The inevitable result of folding was that the additional thicknesses should be dispensed with; this left a strip about 14 feet long and 8 inches wide. As officials, the bishops all wore the pallium, eventually ornamented with crosses; bishops still wear it in the East, but in the West it has come to be treated as exclusively an archiepiscopal ornament. It is also to be noted that in the West the character of the pallium was altered from that of a long, narrow strip to a Y-shaped yoke put on over the head and held in place on the shoulders by golden pins.

The stole (*orarium* and *epitrachelion*) was originally a long, large napkin worn round the neck by all classes of people, including slaves. By the 4th century the deacons of the East were wearing the orarium on the left shoulder, but it was certainly in connection with practical necessities involved in administering the Eucharist. Several centuries later it was adopted for deacons by the West. Just when the stole for priests (*epitrachelion*) and bishops became an exclusively hieratic garment is not clear, but it is universal by the 7th century. Scholars are at a loss to explain the derivation of the ecclesiastical use of the word stole from the Greek use of the word to mean a long, flowing robe. All Western stoles are now long, slender pieces of material richly decorated, worn in the manner prescribed. The priest's stole in the East is fastened down the front, and is, therefore, put on by passing the head through the loop thus formed. In both East and West priests wear the stole under the chasuble when they are vested for the Eucharist;

it is considered appropriate for use at the administration of the several sacraments.

The girdle or cincture (*zone*) was the ordinary means of confining the tunica alba about the waist. It was not until the 8th century that it came to be considered as part of the vestments appropriate to ecclesiastics. Its Latin title, *subcingulum*, is a reference to its being hidden by the alb when pulled out over it. It was anciently richly decorated; now it is ordinarily of finely woven white linen thread, except in the East, where the original rich form is preserved. In both East and West it is used to hold the priest's stole in place when full eucharistic vestments are worn.

The maniple (presumably *pallitza*) was originally a handkerchief carried in the hand. In the West it became an ornamental band matching the stole, and worn on the left forearm; in the East it has retained its ancient distinction as a decoration of honor, but is worn as a lozenge-shaped richly decorated piece of fabric suspended from the right of the wearer's waist. In the East it is worn by all bishops, but only certain of the priests are granted the right to wear it. Another form of it is rectangular shaped and is known as an epigonation.

The miter (*mitra*) is, as the Easterns properly translate it, the crown worn by a bishop. Originally it had reference to the cord which bound either the Phrygian cap or that portion of the toga pulled up over the head and called amictus. The cord eventually hardened into a jeweled band and became the imperial crown; ecclesiastics wore it surrounding their white skull caps as an imperial or royal honor received from the throne itself. The first reliable mention of it is in the 8th century, and it was not until the 11th century that it became the ordinary head-dress of bishops when they were not in church. (The imperial crowns extant are all forms of miters.) The miter was first worn in church in the 12th century. Starting as a bound skull cap it tended to increase in height; thus the Eastern miter is dome-shaped. Although miters were not worn generally until after the collapse of the Byzantine Empire in 1453, the East, like the West, now grants them to abbots and certain archpriests. In the West, in the 12th century, a vertical band was introduced which depressed the center and left two bulbous globes on either side of it. By the 13th century the sides were depressed rather than the center and the familiar triangular shape came into fashion. The original character of the miter has been preserved in at least one aspect of the Western miter and that is in the two ends of the original cord which hang down behind; they are called infulae. In the West there are three kinds of miters: precious, ornamented, and simple. The papal tiara is a development of the Phrygian cap, or phrygium, which was conical in form. It was not until the 12th century that ornamental bands came to be added. The first coronet as such appeared in the 13th century; the second was added in the 14th century by Boniface VIII (r. 1294-1303); one of his successors, Clement V (r. 1305-1314), is credited with having added the third. As the coronets were added, the cone took on an increasingly bulbous shape. The luxurious taste of the Renaissance produced some incredibly valuable tiaras for the popes of that period.

The pastoral staff (*paterissa*) is first men-

tioned in the 5th century, but the reference is clearly to a staff of office symbolic of imperial authority delegated to a bishop. The crook form at the top, which is doubled in the East, seems to have developed from the lituus of ancient days. The title of this staff in Latin, *baculum*, would seem to indicate that the staff was originally regarded as a scepter, which is still true in the East. Needless to say, the symbolism of the "shepherd's staff" is first heard of in the 11th century, and in England. The paterissa did not come into general use by bishops in the East until the 15th century. In both the East and West, abbots and, later, abbesses have come to have the privilege of carrying this staff. The decorated napkin by which the staff is held is called the sudarium or vexillum.

The pectoral cross (*staurós*) had its origin in the reliquaries which were commonly worn by all Christians from the late 4th century on. In the East it is still worn by all the clergy, although archpriests are granted more elaborate and richer versions of it. In the West, it developed into an exclusively episcopal ornament worn over all but eucharistic vestments; the custom grew slowly, however, for the first reliable instance mentioned is in the 13th century, and certainly did not become a general practice until the end of the 17th century.

The cassock (*anteri*) is a long, close-fitting coat. In the West it was originally a garb common to all people, and it was not until the 11th century that it became specifically the standard ecclesiastical undergarment. In the medieval period it was often lined with fur and known as a pelisse—hence superpellicium, or surplice, describes a garment worn over a pelisse. The dress cassock of the West has a short cape, double-over sleeves to the elbow, and deep turn-back cuffs; it is known as a soutane. Ordinary clergy wear black; bishops, purple; cardinals, scarlet. Trained cassocks did not become popular until the 16th century.

The gown (*rasson*) has also been used by both East and West. In the East, the cassocks are often of white, but are covered with a black or blue loose-sleeved gown much like the Persian caftan in cut. In the West, the exterior gown was common to all the learned or leisured classes well into the 15th century, but from that time on it became the exclusive habit of ecclesiastical, judicial, and academic groups. There seems to be little authority for deriving preaching gowns, judges' gowns, and academic gowns from the Benedictine habit.

In addition to the foregoing the East has certain vestments and ornaments peculiar to itself. The cuffs (*epimanikia*) are stiff coverings laced on the forearms of a member of the clergy when he is vested in the sticharion (or alb). The cuffs had their origin in the imperial bracelets; the first reference to their use by ecclesiastics occurred in the 10th century. At first only bishops used them, but later the practice was adopted by priests, and, after the 15th century, the right to wear them was granted to deacons also. The mantle (*mandyas*) is a large flowing black cape joined at the neck and at the feet and is the required choir habit of monks. The bishops, all being monks, wear it with horizontal colored stripes introduced into the design and four squares of velvet ornamenting the panels where the cape joins. Small bells of silver are frequently attached to the bottom of the bishop's

mantle. The headgear, *kamilavka*—*kalimmathion* in Greek—and *skufya*, is in the former case a hat worn by all Greek clergy as a civil distinction (the Greek form has a shallow cone-shaped projection on the top), and by Slavic priests as a distinction granted by metropolitans; in the latter case (*skufya*), it is a pointed skull cap worn by the Slavs as a distinction. The *kamilavka*, when worn by one entitled to it, is draped with the monastic veil. The veil is black in the case of all except Slavic patriarchs and metropolitans, who substitute white for black. The patriarch of Moscow wears a special head covering which may best be described as similar to a round-topped white hood with two long lappets coming down on either side of the face; the portion covering the head is embroidered with a representation of one of the cherubim; the lappets have richly worked crosses at the bottom, and on the exact center of the top of the hood stands a jeweled cross. The panagia (*encolpion*) is the pectoral image which is the exclusive mark of a bishop. Anciently, it was a reliquary, but since medieval times it has been a crowned medallion of the Virgin and Child.

A number of vestments are characteristic of the West and have no counterparts in the official vestments of the East. The surplice is an 11th century amplification of the alb, made to be worn over the cassock. It is always of white and traditionally is supposed to reach nearly to the feet. A length of 10 inches from the ground was prescribed by 16th century directions. Its wide sleeves were designed both for convenience and warmth. From the 14th century on the surplice has been part of the habit of the clergy and of male choristers. An extremely abbreviated form of the surplice, popular on the continent of Europe, is known as a cotta.

The rochet is a development of the tunic which might best be described as the white linen cassock of dignitaries; it has been worn as such from the 13th century. Servers in England have worn it, but this dates from an earlier practice. From the 14th century on, the linen used became very fine, and the garment was somewhat shortened, but it still continued to reach below the knees until the 19th century. The cassock cuffs turned back over its sleeves to produce a finished effect. The frilled cuffs of linen seen in 18th century pictures were attached to the shirt worn under the cassock, ecclesiastical outfitters notwithstanding.

The cope is a ceremonial cape edged with fine decoration, called orphreys, and hooded with the material of the orphreys. It is generally considered to be descended from the paenula and is, therefore, in fact, another form of the chasuble. An all-black version of it, known as the *cappa nigra* or *cappa choralis*, is of ancient use in the church. Since the 13th century the decorated cope has become part of the official vestments of the West, even though it has never been confined to the use of clergy alone. The ornamental clasp which holds the top of the cape together is called a morse. The *cappa magna* is an ecclesiastical form of the doctor's cope. It is a cape entirely closed up the front save for an opening for the hands, and has a deep fur hood falling over the shoulders. The color ordinarily corresponds to the color of the cassock worn.

The chimere is a sleeveless mantle worn over the rochet and originally an outdoor garment. In the strict sense it did not become a vestment

until the 17th century. Whether known by this name or by its usual European name, mantelletta, it is ordinarily of one of three colors: scarlet, purple, or black.

The hood, the mozzetta, the almuce, and the tippet, or scarf, all have their origin in the ordinary medieval headgear worn in cold buildings. Prelates came eventually to have theirs made of fur or of rich material fur-lined, and the same distinctions between classes and faculties in the universities produced the system of academic hoods prevailing in Oxford and Cambridge. In brief, the hood is meant to cover the head and is closed at the neck; the mozzetta is an elbow-length cape buttoned up the front with a small hood attached in back; the almuce is a combination hood, shoulder cape, and scarf open down the front; and the scarf or tippet is a long, broad band of material worn around the neck to keep a hood in place.

The amice, which started as a protection for the neck, became a regular part of clerical attire in the 8th century. After the 12th century it was worn on the head, and is still, technically, the first garment put on over the cassock when eucharistic vestments are worn (there are certain occasions when it is worn with a surplice, but these are relatively rare). It is a square of white linen placed over the head and secured by strings which cross the breast and back and are tied when they again meet in the front. After all other vestments are put on, the hood thus formed is permitted to fall back. A scarf version of the amice is known as a fanon or orale.

The tunicle, which started as a shorter tunic to be worn over the alb by the inferior clergy, ended by being identical with the dalmatic in material and design, although occasionally somewhat less ornamented. The medieval pontificals direct that a bishop wear both tunicle and dalmatic under the chasuble.

The ring, worn by bishops by virtue of their office, dates as a custom from the 7th century. It has since then been worn on either the middle or fourth finger of the right hand. Most bishops do not follow the medieval requirements of three rings: a precious stone magnificently set, a less valuable edition for ordinary wear, and a seal ring. Cardinals, abbots, and doctors of certain faculties are granted rings in the Roman Catholic Church.

The headgear of the West is so different from that of the East that it must be treated separately. The early church, following St. Paul's injunctions, was violently opposed to any man wearing headgear in church. The ordinary pileus of the people was a simple round cap worn out of doors. In the 14th century this cap was taken over from the laity. Being made of four pieces, it gradually became square in shape and in this form has been preserved in the "square cap" mentioned in the Canons of 1604. On the continent of Europe the seams hardened into vertical projections; from this development comes the biretta. The hardening and projecting of the top surface of the square cap result in the mortarboard of academic dress.

Bands, the two rectangles of linen which are worn at the throat, are vestigial remains of the "falling band" collar popular in the 17th century; the sides of the original collar have gone, leaving only the front sections. The stock which bound them has, since the latter part of the 19th century, become the ordinary clerical col-

lar. Bands are common to most North European churches, and are ordinarily white, the exception being certain of the French clergy who continue to wear the white-edged black bands first used in mourning for Louis XIV. Some of the Scandinavian churches use ruffs; these ruffs date from the ordinary dignified attire of the latter portion of the 16th century.

There are a number of other items of somewhat restricted use: buskins and sandals, which are the liturgical knee-length stockings and the slippers worn on occasion by major prelates; pontifical gloves, adopted in the 12th century following the lay custom of the time—the episcopal ring is worn over the gloved hand when gloves are worn; and the cross-staff, borne before an archbishop, dating from the 5th century. The rationale, or episcopal breastplate, was a fanciful imitation of the high priest's breastplate; it came into fashion in the 12th century and was obsolete by the late 15th century.

Monastic dress in the West is ordinarily referred to as the habit. The habit includes a long, close-fitting tunic, over which is worn the scapular, a narrow tabard-like rectangle of cloth which hangs down the front and the back. Over these (though not always) is worn the pallium (gown) or cappa (cape). Lastly comes the caputium (hood). Monastic dress had its origin in the clothes of laboring people. There are over a hundred different combinations of these which are distinctive of the particular orders.

The vestments described above cover all those used by the Roman Catholic, Anglican, Lutheran, and Presbyterian churches. It is probably not necessary to point out that no one of these churches uses all the vestments listed.

Mention must be made of the several color sequences used by the liturgical churches. The East follows the ancient practice, which knew but two kinds, festival and penitential. The Roman Catholic Church uses white, red, violet, green, black, and rose. The Lutheran Church follows this same scheme (known as the Western Use), only excepting the use of rose. The Sarum Use (the Use of Salisbury Cathedral) includes "best," "second best," red, white, blue, black, and unbleached linen.

EDWARD N. WEST,
*Canon of the Cathedral of St. John the Divine,
New York City.*

COSTUS, a product of an annual herb grown on the mountain slopes of the Kashmir (Cashmere) valley. The dried root of *Saussurea lappa* is commonly known as costus, and is mainly used as an ingredient of incense in the Orient. It is also employed as a protection against moths in bales of shawls and furs. The root yields a small amount of costus oil, which finds use as a fixative in perfumery and toilet products. Formerly as much as 2 million pounds of costus root were exported annually, but production appears to have declined in recent years.

COSWAY, Maria Cecilia Louisa Hadfield, Irish-Italian painter: b. Florence, Italy, 1759; d. Lodi, Italy, 1838. She studied art in Rome and then went to England, where she developed her skill as a miniaturist of mythological subjects. She exhibited at the Royal Academy of Arts in 1781 and in the same year married Richard Cosway (q.v.). She was a contributor to John Boydell's Shakespeare Gallery. Much of her life was spent on the continent. Thomas Jefferson, who met her during his stay in France, became greatly attached to her. In later years she established a school for young ladies at Lodi, and was made a baroness by Emperor Francis II. Her only child died at an early age.

COSWAY, Richard, English painter and miniaturist: b. Okeford, near Bampton, Devonshire, Oct. or Nov. 1742; d. Edgeware, July 4, 1821. He studied in London and from 1761 on contributed pictures to the various exhibitions there, showing for the first time at the Royal Academy of Arts in 1770. He was principal painter to the Prince of Wales and enjoyed an enormous and lucrative popularity as a fashionable portrait painter in aristocratic circles in Paris as well as London. Early in his career he had worked for jewelers, painting miniatures to adorn snuffboxes, and he is known today chiefly for his perfection of the technique of painting miniatures on ivory.

COT, kôt, 'Pierre Auguste, French painter: b. Bédarieux, Department of Hérault, 1837; d. Paris, Aug. 18, 1883. He studied under Léon Cogniet, Alexandre Cabanel, and Adolphe William Bouguereau. Among his works are *Spring Time* (Brooklyn Museum) and *The Storm*, often called *Paul and Virginia* (Metropolitan Museum of Art, New York City).

COTA DE MAGAQUE, kō'tā thā mā-gwā'kā, Rodrigo, Spanish poet: b. Toledo, Spain; d. before 1495. Jewish in religious background, he became a Christian and served the Inquisition in the persecution of other converted Jews. He was the author of the dramatic poem *Diálogo entre el amor y un viejo*, in which an old man is tempted by Love and, after long resistance and much argument, yields, only to find himself now the object of Love's ridicule. The dialogue, first printed in the *Cancionero general* of 1511, had an influence on the development of the drama and continues to be of interest for its poetic merit. Cota de Magaque also wrote a burlesque epithalamium (c.1472). Scholarship refutes his authorship of the first act of Fernando de Rojas' *La Celestina* and of the political satire *Coplas de Mingo Revulgo*, both of which have been attributed to him. He is sometimes called *el viejo*, the elder, to distinguish him from his nephew *el mozo*, the younger.

COTABATO, kō'tā-bā'tō, province, the Philippines. Located in the southern part of the island of Mindanao, it is bordered on the north by Lanao and Bukidnon provinces, on the east by Davao Province, on the south by the Celebes Sea, and on the west by Illana Bay and Moro Gulf. With its dependent islands it covers an area of 8,909 square miles. Mountains in the south and in the northern and eastern border regions include two volcanoes: Mount Apo, on the eastern boundary, at 9,689 feet the highest

mountain in the Philippines; and Mount Ragang, on the northern boundary. The Rio Grande de Mindanao, known in the northeast region as the Pulangi, crosses the province; in its course through the north central area it drains the Liguasan Marsh. The province is fertile but largely undeveloped, with rice, coconuts, and rubber grown. Moros comprise the bulk of the population. The capital is Cotabato, and the largest villages are Dulawan, Midsayap, and Talayan. Pop. (1948) 439,669.

COTE, Marc-Aurèle Suzor. See SUZOR-CÔTÉ, MARC-AURÈLE.

COTE D'OR, kôt'-dôr', department, France, formed of part of the old province of Burgundy. Located in east central France and having an area of 3,393 square miles, the department is bounded on the north by the departments of Aube and Haute-Marne, on the east by Haute-Saône and Jura, on the south by Saône-et-Loire, and on the west by Nièvre and Yonne. It is crossed by part of Langres Plateau, north of Dijon, and by the Côte d'Or mountain chain. Rivers include the Saône, in the southeast, the only navigable river; the Seine, which rises in the northwest and, together with its tributary the Ource, drains a large wooded district; and the Arroux, a tributary of the Loire. Anthracite mining is carried on, and there are large quantities of iron. Vineyards in the east yield the department's most important economic product, with the wines from Beaune and from the Saint-Georges vineyard of Nuits being best known. Other products include vegetables, cereals, and manufactured metal products. The department is divided into three arrondissements (Dijon, Beaune, and Monthard), 37 cantons, and 717 communes. The capital is Dijon. Pop. (1946) 335,602.

COTE D'OR (hill, or hillside, of gold), a chain of mountains in France which separates the basin of the Saône from the basins of the Seine and the Loire, and connects the Cévennes range with the Vosges range. The name has special reference to a small chain in the Department of Côte d'Or whose eastern slopes have vineyards famous for their excellent and valuable wine—hence the name Côte d'Or. The chain, about 31 miles in length and averaging 1,500 feet in altitude, extends northeast from the Nolay-Chagny area in the south of the department to Dijon in the east central region.

COTENTIN PENINSULA, region of Normandy, northwest France, projecting into the English Channel across from the Isle of Wight. It forms the northern part of the Department of Manche. Once a Norman county, it takes its name from its former capital, Coutances. Cherbourg, the principal city, has the only good harbor. The countryside is characterized by rolling terrain, hedgerows, small fields, and apple orchards. Livestock-raising and dairying are important occupations. Allied forces invaded the peninsula on June 6, 1944. (See WORLD WAR II.)

COTES, kôts, Roger, English mathematician: b. Burbage, Leicestershire, July 10, 1682; d. Cambridge, England, June 5, 1716. He was educated at St. Paul's School and at Trinity

College, Cambridge, where, in 1706, he became first Plumian professor of astronomy and natural philosophy. In 1713 there appeared a new edition of Newton's *Principia*, thoroughly revised by the author with the assistance of Cotes and containing a preface by the latter which defended Newton's system against the Cartesians and others. Cotes published only one independent work, a treatise on ratios entitled *Logometria* (1713). After his death Robert Smith, his successor as Plumian professor, edited *Harmonia Mensurarum, sive Analysis et Synthesis per Rationum et Angularum Mensuras: Accedunt alia Opuscula Mathematica per Rogerum Cotesium* (1722) and his *Hydrostatical and Pneumatical Lectures* (1738). The latter was translated into French by Pierre Charles Lemonnier in 1740. Cotes did pioneer work in practical astronomy; his description of the meteor of March 6, 1716, was published in 1720. His name is still given to a theorem discovered by him relative to the circle. The correspondence of Newton and Cotes was published in 1850. Newton is reported to have once said, "Had Cotes lived we might have known something."

COTES, Sara Jeannette Duncan, Canadian author: b. Brantford, Ontario, 1862; d. Ashmead, England, July 22, 1922. She entered journalism as a correspondent for several Canadian and American newspapers at the Cotton Centennial in New Orleans in 1884-1885, and later, writing under the pseudonym Garth Grafton, served on the staffs of the *Washington Post*, the *Toronto Globe*, and the *Montreal Star*. In 1891 she married Everard Cotes and accompanied him to India, where she spent most of her later life. Her novels, marked by humor, include *A Social Departure* (1890); *An American Girl in London* (1891); *Those Delightful Americans* (1902); *The Imperialist* (1904); *His Royal Happiness* (1915); and such stories of Indian life as *The Simple Adventures of a Mem Sahib* (1893) and *The Story of Sonny Sahib* (1894).

COTES-DU-NORD, kô't'du-nôr', department, France, forming part of ancient Brittany. Located in northwestern France, it is bounded on the north by the English Channel, east by the Department of Ile-et-Vilaine, south by the Department of Morbihan, and west by the Department of Finistère. The department has an area of 2,787 square miles. The much indented coast has many shoals and small offshore islands. The interior has poor soil and is generally level despite low mountains in the south and west. Streams flowing toward the English Channel are short ones such as the Rance and the Trieux; there are longer streams flowing south. Cattle and horses are raised, and principal agricultural products include fruit, flax, hemp, and grain. The department's fishing industry has declined somewhat, as has its linen and sail-cloth industries. Côtes-du-Nord is divided into four arrondissements (Dinon, Guingamp, Lannion, and Saint-Brieuc), 48 cantons, and 390 communes. The capital is Saint-Brieuc. Pop. (1946) 526,955.

COTGRAVE, kô't'grāv, Randle, English lexicographer: b. Cheshire; d. 1634?. He entered St. John's College, Cambridge, in 1587. Later he became secretary to William Cecil, 1st Baron Burghley. When, in 1611, he published

his French-English dictionary he dedicated it to Burghley. The dictionary, Cotgrave's sole reason for being remembered, was the first of its kind. It was remarkably accurate and reliable for its time, and has been several times reissued. A storehouse of 16th-17th century English and French forms, it has been of great value to linguistic researchers. Cotgrave's life remains otherwise obscure. It is known that he was still alive when the second edition of his dictionary was published, in 1632.

COTHURNUS. See BUSKIN.

COTILLION or **COTILLON**, both kô-tîl'yün, a ballroom dance originating in an English country-dance called the round for eight and transformed by the French in Louis XIV's reign. Cotillon means "petticoat" and apparently was adopted as the name for the dance from the words of a song popular at the time. In its French transformation originally requiring the dancing of a number of figures in somewhat classical style, the cotillion became, as it developed, a brisk, spirited dance, resembling the quadrille, which superseded it. It was popular in 19th century England and America. Danced to waltzes, polkas, and mazurkas, it permitted for an unlimited number of couples following a leading couple in an elaborate series of steps and figures, and successively changing partners. In time the cotillion came to be the dance closing a grand ball. The distribution of a variety of small gifts to the assemblage was one of its features.

COTIN, kô'tân', Charles, French abbé and poet: b. Paris, 1604; d. there, 1682. Attached to the court as a councilor and almoner, he frequented the fashionable salons, including the Hôtel de Rambouillet. In 1655 he was elected to the Académie Française. His poems and other literary works appeared as *Recueil d'Enigmes* (1646), *Oeuvres Mêlées* (1659), and *Oeuvres Galantes* (1663-1665). The poems were marked both for their mediocrity and their preciousness. Derided in the satires of Nicolas Boileau-Despréaux, Cotin replied in *La Critique Désintéressée* (1666). He acquired another enemy in Molière, who introduced him on the stage in *Les Femmes Savantes* and exposed him to ridicule under the name Trissotin (originally written as Tricotin). He was a successful preacher, and he had extensive knowledge in Oriental and classical studies.

COTINGIDAE, kô-tin'jī-dē, a family of almost 100 species of passerine birds, the cotingas, allied to the American flycatchers, and inhabiting the forests of tropical America. One species, the rose-throated becard, reaches the southwestern United States. The cotingas are of moderate size; they usually frequent tall trees and feed on such creatures as insects and snails and on berries and other small fruits. The plumage is sometimes plain rufous, green, or gray, the females being nearly always dull, although many of the males are very brilliant and some species are extraordinary among forest birds in being pure white. The cotingas include some celebrated South American species, such as the bellbird (q.v.), umbrella bird (q.v.), and cock of the rock. Many of them are ornamented with wattles and long plumes, which they display

in elaborate courtship postures and dances. The voice of the bellbird and some of the other cotingas is powerful and occasionally musical.

DEAN AMADON.

COTMAN, kōt'mēn, John Sell, English landscape painter and etcher: b. Norwich, England, May 16, 1782; d. London, July 24, 1842. Although his work was not considered of great importance in his own day, he subsequently became recognized as one of the leading figures of the Norwich school. He was an excellent draftsman, and painted well in both oils and water color. He published several volumes of excellent architectural etchings made in Norfolk and Normandy.

Two of his sons, MILES EDMOND (1810-1858) and JOSEPH JOHN EDMOND, were landscape painters of merit, and his nephew, FREDERIC GEORGE COTMAN (1850-1920), achieved distinction as a water-color artist.

COTO, or **COTO BARK**, kō'tō, the reddish-brown, aromatic, and slightly bitter bark from various South American sources, one of which being *Palicourea densiflora*, order Rubiaceae. It contains the substance *Cotoin*, $C_{14}H_{12}O_4$, which has been used in the treatment of intestinal disorders.

COTONEASTER, kō-tō-nē-ās'tēr, a genus of plants of the natural family Rosaceae, closely related to *Crataegus*, with fruit consisting of bony carpels, each containing two similar ovules. In the United States and England it is an ornamental shrub, having bright red fruit which remains throughout the winter. It thrives in any good, well-drained garden soil not too shadily situated.

COTONOU or **KOTONU**, kō-tō-nō', seaport, French West Africa, in Dahomey, 15 miles west-southwest of Porto-Novo. It is an export and manufacturing center for a rich agricultural region. Its harbor is poor but it is on a railroad and has an airport. Pop. (1949) c.22,900.

COTOPAXI, kō-tō-pāk'si, the most remarkable volcanic mountain of the Andes, in Ecuador, 30 miles south of Quito. It is 19,498 feet in height and its upper portion forms a perfect cone, permanently snow-covered on the eastern side, its side kept bare by the moist trade winds of the Atlantic. On the southern slope is a bare cone called *El Picacho* ("the beak") or *Cabeza del Inca* ("the Inca's head").

Many devastating eruptions have occurred, the earliest recorded in 1532, the latest in 1903. In 1698 the eruption destroyed the city of Tacunga, three fourths of its inhabitants, and surrounding settlements; in 1744 its roarings were heard as far as Honda, on the Magdalena River, 600 miles distant. The peak was climbed by Wilhelm Reiss in 1872 and explored by Edward Whymper in 1880.

COTSWOLD. See **SHEEP**—*The Mutton Type*.

COTSWORTH, Moses Bruines, English advocate of calendar reform: b. Willitott, Yorkshire, Dec. 3, 1859; d. Vancouver, British Columbia, Canada, June 4, 1943. In 1922 he organized the International Fixed Calendar League in

an effort to have the 13-month calendar devised by him adopted throughout the world. Placed before the League of Nations in 1931, his proposal was tabled until 1935, at which time international affairs were too pressing for it to receive consideration.

Cotsworth proposed a fixed calendar of 13 months of 28 days each, the 13th month to be called "Sol" and to come between June and July; an odd "Year Day" was to be added to December; and a like addition to be made to June, also without a weekday name, for leap year.

COTTA, kōt'ä, the name of a family of German publishers, which included the theologian, Johann Friedrich Cotta (1701-1779) of the University of Tübingen, as well as the proprietors of the J. G. Cotta'sche Buchhandlung. This publishing house was founded by JOHANN GEORG COTTA (1631-1692), who took over the management of the bookselling firm of Philipp Braun in Tübingen in 1659, and established the business which later bore his name.

JOHANN FRIEDRICH, BARON COTTA VON COTTENDORF (1764-1832), the great-grandson of the latter, was born in Stuttgart where his father, Christoph Friedrich Cotta (1730-1807), had established a printing house at the court. Taking over the leadership of the firm in 1787, Cotta embarked on a publishing career which played an important part in the distribution of German literature and ideas in his time. Among the many periodicals issued by him were the *Allgemeine Zeitung*, planned in 1793 with Schiller and first appearing in 1798 in Tübingen, and the *Horen*, notable for its role in the lives of Schiller and Goethe. Inaugurated in 1795 by Cotta and Schiller, this publication brought Cotta in close contact with Goethe, Herder, Fichte, and other great German writers who contributed to this venture. Although renowned as a bookseller, Cotta also was noteworthy as a liberal statesman and a champion of scientific agriculture, and for installing the first steam printing press in Augsburg.

JOHANN GEORG, BARON COTTA VON COTTENDORF (1796-1863), the son of the preceding, succeeded his father to the publishing business in 1832. He extended the activities of the firm by purchasing publishing houses in Leipzig and Landshut. However, under his son, Karl von Cotta (1835-1888), these connections were eventually relinquished and after his death the firm was sold to Adolf and Paul Kröner of Stuttgart (1889).

COTTAGE GROVE, town, Oregon, in Lane county, 21 miles south of Eugene on the coast fork of the Willamette River. It is served by the Southern Pacific Railroad and U.S. Highway No. 99. A growing trading center of a rich agricultural region, it is a lumbering, stockraising, dairying, and fruitgrowing community. The Bohemia Mountain Mining District and Cottage Grove and Dorena dams are nearby.

Cottage Grove was first settled in 1880 and incorporated in 1900. It is governed by mayor and city council. Pop. (1950) 3,536.

COTTER'S SATURDAY NIGHT, *The*, a poem written by Robert Burns while farming and writing poetry at Mossgiel, his brother's farm near Mauchline, Scotland in 1785. Although of hybrid origin—the plan and title suggested

by Robert Fergusson's *Farmer's Ingle*, the scene and sentiment reminiscent of Gray and Goldsmith, the form a medley of English and Scottish idiom in Spenserian stanza—the poem is original in inspiration and spirit. The poet's brother Gilbert tells us that "the Cotter is an exact copy of my father in his manners, his family devotions, and exhortations." Burns has pictured with genuine affection the home-coming of "the toil-worn Cotter" and his bairns, the welcome to the "neibor lad," "the cheerful supper," the family worship around the ingle. This homely realism and sincerity of feeling have given the poem an enduring place in English literature. Modern readers may find both forced sentimentality and artificial poetry in those stanzas in which Burns wholly abandons his native idiom, and with it his poetic instinct, to praise simple love and piety and denounce villainy and religion's pomp. But no one can fail to feel, in the scene itself and in the final stanzas, that truest love of country that is love of man. It is this humanity that has made Burns not only "the patriot-bard," but the poet of democracy, and *The Cotter's Saturday Night* not only a Scottish interior, but an idyl of the people.

COTTET, kô-tě', Charles, French landscape and genre painter: b. Le Puy, Haute-Loire, France, July 12, 1863; d. Paris, Sept. 25, 1925. He studied under Pierre Puvis de Chavannes and Alfred Philippe Roll. At first an impressionist, he later helped found the Société Nationale des Beaux-Arts. He was known chiefly as a painter of Breton subjects. A cycle of 10 landscapes entitled *The Country of the Sea*, several of which are in the Luxembourg, attracted wide attention. He painted many Venetian, Egyptian, Algerian, and Spanish subjects. There are also a few Icelandic landscapes by him. His paintings include *The Port of Camaret* and others in the Luxembourg; *Going to Church in Brittany* (Vienna); *A Moonlight Night* (Philadelphia); *Breton Women in Mourning* (Cincinnati); he is represented also in Buffalo and Providence. He was an officer of the Legion of Honor.

COTTIER TENURE, kôt'î-ēr, a system of tenure according to which laborers could rent small portions of land directly from the owner, or from a farmer, often giving personal service as part of the rent, and holding by annual tenancy. Later the term "cottiers" was used to denote peasant farmers whose rent was determined by competition. Ireland was the chief home of this system. The same class was called "crofter" in the west of Scotland. The enactment of land laws by Parliament eliminated some of the worst features of this system, and Irish independence helped correct abuses in that country.

COTTIN, kôt-tăn', Marie (called SOPHIE; nee RISTEAU), French novelist: b. Paris, France, March 22, 1770; d. Champlan, April 25, 1807. Her best-known work is *Élisabeth ou les exilés de Sibérie* (1806), which was imitated by Xavier de Maistre in *La jeune Sibérienne*. It was translated into English by G. R. Lockwood (New York 1869). Other novels are *Claire d'Albe*; *Malvina*; *Amélie de Mansfield*; and *Mothilde*.

Consult Kavanaugh, Julia, *French Women of Letters* (Leipzig 1862).

COTTLE, kôt'l, Joseph, English bookseller and author: b. Gloucestershire, England, 1770;

d. Bristol, June 7, 1853. The earliest poems of Robert Southey and Samuel Taylor Coleridge were published by him, and they acknowledged their indebtedness to him in later life. He also published Coleridge's periodical, *The Watchman* and *Lyrical Ballads of Coleridge and Wordsworth*.

His own writings include *Malvern Hills*; *John the Baptist*; *Alfred, an Epic Poem*; and *The Messiah*. Cottle's poems and those of his brother Amos are satirized in Lord Byron's *English Bards and Scotch Reviewers*. A prose work, *Early Recollections*, is in bad taste, though it has some details of value regarding Coleridge's early life.

COTTON, kô-tôn', Aimé Auguste, French physicist: b. Bourg-en-Bresse, Oct. 9, 1869. After studying at the lycées of Bourg and Clermont-Ferrand he matriculated at the École Normale Supérieure (1889) where J. B. Perrin and Paul Langevin were fellow-students. Awarded a scholarship in the physics laboratory in 1893, he advanced regularly in the university hierarchy, was associate professor at Toulouse, and from 1900 to 1915 was professor at the École Normale. After World War I he held the chair of physical research at the Sorbonne, was elected to the Academy of Sciences in 1923 and became its president in 1947. With H. Mouton he discovered double refraction of liquids in a magnetic field, and with Pierre Weiss made an important deduction from the Zeeman effect (q.v.). He is the author of *Le Phénomène de Zeeman* (1900); *Les Ultra-microscopes et les objets ultra-microscopiques* (1906); and *Symétrie des critères et symétrie moléculaire* (1914).

COTTON, Charles, English poet and translator: b. Beresford, Staffordshire, England, April 28, 1630; d. Westminster, London; burial date, Feb. 16, 1687. In 1658 he inherited his father's estate on the Dove River, on the banks of which he built a fishing house in which he frequently entertained his friend Izaak Walton. His writings included *Scarronides, or Virgil Travestie* (1664; 1670), the first and fourth books of Virgil's *Aeneid* in burlesque; and a translation of Montaigne's *Essays* (1685), his best work. He also translated a tragedy of Corneille, *Horace* (1671). A volume of his *Poems on Several Occasions* was published posthumously. He is best remembered for his addition to the fifth edition of Walton's *Compleat Angler* (1676) called "Instructions How to Angle for a Trout and Grayling in a Clear Stream." His poetry won praise from Charles Lamb and William Wordsworth.

COTTON, John, American Puritan clergyman: b. Derby, England, Dec. 4, 1584; d. Boston, Mass., Dec. 23, 1652. The son of Roland Cotton, a well-to-do lawyer, he became a student at Trinity College, Cambridge, and was awarded the A.B. degree in 1603 and A.M. in 1606. Proficiency in Hebrew won him a fellowship at Emmanuel College, which had been founded by a Puritan and was the most Puritanically inclined of all the Cambridge colleges. Ordained deacon and priest in 1610, he received the B.D. degree three years later. Meanwhile, in 1612, he had been chosen vicar of St. Botolph's Church in Boston, Lincolnshire. His gradual abandonment of Church of England forms of worship began about 1615. During his 20-year tenure of the vicarage he gained a reputation as a brilliant

preacher and controversialist, and inclining in his doctrines and practices toward the Puritan form of worship. Cited to appear before the Court of High Commission in 1632, he sought safety in flight, arriving in Boston on Sept. 4, 1633. On October 10, he was ordained teacher of the church there, an office he held until his death. He attained great influence in the Massachusetts Bay Colony. He was a critic of Greek, wrote Latin with elegance, and could speak Hebrew. His sermons were noted for their simplicity and effectiveness. During the course of his celebrated controversy with Roger Williams he published *The Keyes of the Kingdom of Heaven* (1644) and *The Bloudy Tenent, Washed, and Made White in the Bloud of the Lambe* (1647). He maintained that the church is constituted of elders and brethren, and that the elders are entrusted with government insofar as admissions and excommunications are concerned, but that nothing of common concern can be imposed upon the brethren against their consent. He defended the interference of civil power in religious matters for the support of truth, maintaining the duty, for the good of church and people, of putting away those who after repeated admonitions persist in rejecting fundamental points of doctrine or worship. Cotton published more than 50 works, including *An Abstract of the Lawes of New England* (1641); *The Way of Life* (1641); *The Way of the Churches of Christ in New-England* (1645); *Milk for Babes* (1646), his famous children's catechism; *The Way of Congregational Churches Cleared* (1648); *The New Covenant* (1654); and *The Covenant of Grace* (1655).

Consult *The Writings of Roger Williams*, vols. 1-4 (Providence 1866-1870); Walker, Williston, *Ten New England Leaders* (New York 1901); Parkes, H. B., "John Cotton and Roger Williams Debate Toleration, 1644-1652," *New England Quarterly*, 4:735-56 (1931).

COTTON, Sir Robert Bruce, English antiquary: b. Denton, Huntingdonshire, Jan. 22, 1571; d. May 6, 1631. He was educated at Westminster School and Cambridge University, receiving his B.A. degree in 1685. Settling in London, he devoted himself to antiquarian studies and to the collection of ancient manuscripts pertaining to English history. The Antiquarian Society met at his home, and he opened his library to William Camden, John Speed, Sir Walter Raleigh, Ben Jonson, and Francis Bacon. He sat in Parliament under James I, who made him a baronet in 1611, and he was a member of the first and third Parliaments of Charles I's reign. He was opposed to the growth of royal power, and in 1629, falsely accused of having written an obnoxious political tract, was imprisoned for eight months. Although he was pardoned, his library was confiscated. Of his many works, only two—*The Raigne of Henry III* (1627) and *The Dangers wherein the Kingdom now standeth* (1628)—appeared in his lifetime. A collection of 14 of his tracts, *Cottoni Posthuma*, was published by James Howell in 1657. See also COTTONIAN LIBRARY.

COTTON. Cotton in the botanical sense refers to the plant which has long been famous for its fluffy fiber, and for many decades for both its fiber and its seed. Cotton fiber, which is also referred to merely as cotton, consists of unicellular hairs varying in length from a fraction of an inch to two inches or slightly more. The fibers are attached to a seed about the size of a

small pea and have a spiral twist that makes them especially valuable for spinning—by far their most important use. Cottonseed, long considered almost worthless (except for planting purposes) after the lint or fiber had been removed, is now highly valued for its oil, cake, meal, and linters (see separate article on COTTONSEED AND COTTONSEED PRODUCTS).

The history and importance of cotton, its characteristics, production, marketing, manufacture, and economic problems, are discussed under the following headings:

- | | |
|--|--|
| 1. Historical Background and Importance | 5. Production, Supplies, and International Trade |
| 2. The Cotton Plant | 6. Manufacturing and Textile Distribution |
| 3. Production and Ginning Practices and Facilities | 7. Economic Problems |
| 4. Marketing and Prices | |

1. HISTORICAL BACKGROUND AND IMPORTANCE.

The origin of cotton and the country where it was first used have never been definitely determined. It has long been indicated, however, that cotton cloth was being produced in India as early as 1500 B.C., and that about 1500 A.D. India was perhaps the center of the cotton industry. In the 1920's, archaeological evidence was discovered indicating that as early as about 3000 B.C. cotton was being used in India to make fabric and string. From India the culture of cotton and the making of cotton cloth are believed to have spread to Persia (Iran), China, and Japan. In the last two countries vested interests in silk actively opposed the use of cotton.

The writings of Herodotus and Pliny report that cotton fiber was known to the Greeks and Romans. Columbus found it employed by natives of the New World. In the conquest of Mexico and Peru cotton cloth was discovered to be in use, and ancient Peruvian tombs have yielded mummy cloths of cotton. In the early years of the Christian era mummy cloths from Egypt are said to have been made of linen, but there are other indications that the Egyptians used cotton cloth in the same period.

Before the Industrial Revolution most of the yarn cloth produced throughout the world was either handmade or made with very crude equipment. In the second half of the 18th century many new machines for making cloth were invented in England. Since the use of these machines was most efficient when they were established in large units, the factory system of manufacture was developed.

The English inventions of textile machinery were very carefully guarded. No drawings of the machines were permitted, and workers were forbidden to disclose how they operated. In 1789, however, Samuel Slater (q.v.) brought to the United States a working knowledge of the textile machinery of Great Britain, which he had gained as an apprentice under Jedediah Strutt, partner of the inventor Sir Richard Arkwright. He had the machinery reproduced from memory and in 1793 built at Pawtucket, R. I., the first cotton mill in the United States. See also TEXTILE MACHINERY.

Economic Importance.—Cotton is one of the most valuable of all plants. Over the years it has returned to farmers in the United States more cash annually than any other crop. In 1950, for example, cash income from the cotton crop, including both lint and seed, totaled \$2,473,106,000, as compared with \$1,812,116,000 from wheat,

the next most important cash crop. The farm value of the corn crop is considerably larger than that of cotton, but much of this crop is not sold but used for feed on the farms where it is produced.

More United States citizens depend on cotton for an important source of their income than on any other crop. It has been estimated that from 12,000,000 to 14,000,000 persons in the United States depend directly on this crop for at least a part of their livelihood. On some 1,500,000 cotton-producing farms there are 9,000,000 or 10,000,000 persons—approximately one third of the farm population of the United States—who rely on cotton for a considerable part of their income. About 3,000,000 or more persons derive their income from cotton textile and garment manufacturing, and cotton warehousing, ginning, distributing, and marketing employ an estimated 500,000 persons.

In addition to those directly dependent on cotton and the cotton industry, millions of persons throughout the United States are vitally affected by cotton. They include persons engaged in the manufacture, wholesaling, transportation, and retailing of commodities made by other industries and sold to those who produce, merchandise, transport, and manufacture cotton. Also included are bankers, physicians, lawyers, and others performing professional or personal services.

The importance of the cotton plant is due to the many uses of its fiber and its seed. The uses of cotton fiber are so varied that it is by far the most important of all textile fibers. In fact, cotton provides more cloth for mankind than all other fibers combined. During the period 1935-1939, cotton accounted for slightly more than half, by weight, of all fibers used in the world. Jute, the next most important fiber, supplied less than 15 per cent of the total. Despite the increased consumption of synthetic fibers during and after World War II, cotton probably still accounted for at least half the world's fiber consumption in 1952.

Because of the expanding consumption of man-made fibers, cotton's relative importance as an apparel fiber has declined. In 1929 cotton accounted for 84.83 per cent, by weight, of the United States consumption of apparel fibers (cotton, wool, rayon, flax, and silk). By 1939 cotton's share had decreased to 79.68 per cent of the total, and by 1949 to 71.86 per cent. (See also section on *Economic Problems*.)

During World War II cotton was called America's No. 1 crop because it met so many vital war needs. For each of the millions of 478-pound bales of lint cotton produced in the United States, almost 900 pounds of cottonseed were produced. From the fiber were manufactured some 10,000 items of clothing, shelter, and fighting equipment for the army—ranging from socks to fabrics for airplane tires and bulletproof gasoline tanks, from balloon fabrics to parachutes, from mosquito netting to camouflage screens for army installations. Cotton fiber also supplied farmers, war plant workers, and other civilians with such essentials as bags for food products, clothing, and hospital supplies, and furnished war and other industrial plants with fabrics and other parts for the products which they manufactured. Cottonseed supplied high-grade vegetable oil for food; protein feed in the form of meal and cake for livestock; hulls for livestock roughage and

chemical uses; and linters for smokeless powder, plastics, and other essential products.

F., *Cotton in Peace and War* (Nashville 1944); Bureau of Agricultural Economics, *Statistics on Cotton and Related Data* (Washington 1951).

(M.R.C.)

2. THE COTTON PLANT. The cotton of commerce is a product of plants of the genus *Gossypium*, a member of the Malvaceae or mallow family. There are many different species of *Gossypium*, but almost all cotton of commercial importance falls into three separate or closely related species. The most important of these is *Gossypium hirsutum*, which includes those cottons developed in the United States from cotton native to Mexico and Central America and commonly known as upland cottons. A second botanical species, of early South American origin, is *Gossypium barbadense*. Generally of longer staple than upland cottons, it includes Egyptian, American Egyptian, and Sea Island cottons and some of the Peruvian and Brazilian varieties. A third group embraces those short-staple cottons native to India and the Far East which are classified as *Gossypium arboreum* and *Gossypium herbaceum*. All the species are said to be of tropical origin.

Upland cottons (*G. hirsutum*) have unspotted white flowers, bolls of four or five locks, and seeds usually well covered with white, brown, or green fuzz in addition to the lint. This type of cotton constitutes a very large part of the United States crop, as well as substantial proportions of the crops of many other countries in both hemispheres, including Argentina, Brazil, China, Mexico, and the Soviet Union.

The cottons classified as *G. arboreum* and *G. herbaceum* are quite closely related botanically. They include many types (formerly designated as species) of cotton sometimes referred to as Asiatic. Short in staple but strong and rather rough, this cotton constitutes most of that grown in India, Iran, parts of China, and some other Asian countries producing smaller quantities.

Cottons of the species *G. barbadense* have yellow flowers with purple spots, bolls mainly with three locks, and black seed from which the fibers are easily detached. The fibers are generally longer in staple than those of almost any of the upland cottons.

Climatic Requirements.—Cotton is a warm-weather plant. For the most part, it is grown commercially in areas with 200 or more days a year free of frost and with a temperature of 70°F. or more during a considerable part of this period. In many parts of the United States cotton belt, the normal monthly mean temperature from May through September is from 70° to over 80°F. Cotton does best in areas where there is plenty of sunshine without prolonged periods of cloudy weather. This is especially true where the boll weevil is present, since it is particularly hard to control this important insect pest when there is much dull, cloudy weather (see section on *Production and Ginning Practices and Facilities*).

Because it requires so long a growing season, cotton is produced almost entirely between lati-

tudes 40°N. and 30°S. In the United States the cotton belt is mainly south of latitude 37°N. In the Soviet Union, however, cotton has been produced as far north as latitude 41°-42°N., or about the same latitude as Chicago, Ill.

Except for areas where the land is irrigated, the cotton plant requires a fair amount of rainfall. It can be grown on unirrigated lands with about 20 inches (or even less) of annual rainfall, or 7 or 8 inches distributed over the growing season. In areas with heavy rainfall throughout the year, cotton does not do so well. In the United States annual precipitation—including rain, hail, sleet, and snow—generally ranges from 40 to 60 inches in the eastern and central parts of the rain-grown sections of the cotton belt to as low as 20 inches in parts of Texas and Oklahoma. In the eastern and central states of the cotton belt, precipitation during the autumn or harvesting period is considerably lighter than in other seasons. Except for their eastern sections, Texas and Oklahoma have a greater average precipitation during the harvesting season than in winter, but it is still less than in most other cotton-producing states.

In tropical regions the growing season of the cotton plant is controlled by moisture or other conditions rather than by frost, as it is in the temperate zone. Here cotton may grow for years, the plant becoming so large that it is referred to as tree cotton. In Peru commercial production of cotton is confined almost entirely to irrigated valleys where much of the cotton is allowed to produce three or four crops from one planting, the plants being cut back to the ground after each crop. As a result of variation in the time of cutting or planting and of control of the water supply, cotton is harvested in Peru on a sizeable scale almost all the year round.

Largely because of wide variation in climatic conditions, harvesting times in several other countries also differ greatly from those in the United States—a significant factor in cotton marketing. When the United States crop is moving to market in greatest volume, from September to December, an important part of the Indian crop is being planted. In southern Brazil, where large quantities of cotton similar to that grown in the United States are produced, harvesting occurs between March and July. In Argentina the crop is only slightly earlier. In the major producing countries of China, the Soviet Union, and Egypt, as well as in a number of countries producing smaller quantities, including Mexico and Turkey, harvesting dates do not differ materially from those of the United States.

Soil Requirements.—When climatic conditions are favorable, cotton may be produced on almost any type and character of soil. It is grown on light, sandy soils, on loams, on heavy clay, and on bottom lands. Yields on the different types of soil, however, vary substantially. On light, sandy soil, unless it is well fertilized, the yield is small. On loams the yield is better, while on bottom lands the yield is normally very good when moisture conditions are favorable.

The most productive soils in the United States outside the irrigated areas are the black, brown, or red well-drained bottom land soils along the rivers and smaller streams of the cotton belt. On somewhat similar soils in the dry but irrigated areas of the southwestern part of the United States, yields per acre average much higher than in other areas of the belt. This is

due not only to the soil, but also to controlled moisture conditions and to smaller damage from insects and diseases, which are checked to a greater extent as a result of climatic conditions. The dark-colored clay lands, such as the black prairie areas of Texas and Alabama, the sandy loams of the coastal plains, and the red subsoil Piedmont lands are also important cotton-producing soils.

Soils, together with moisture conditions (which are affected to an important extent by soil types), have a major bearing on the quality of cotton produced. The rich valley of the Nile River, where moisture conditions are generally quite favorable, has long been noted for its production of long-staple cotton. A very large part of the long-staple cotton produced in the United States is grown in the fertile river bottoms and in irrigated areas. Sandy upland soils normally produce short-staple cotton, particularly if there is an inadequate supply of moisture in the soil. A scarcity of soil moisture will affect adversely the length of the cotton fiber and the fiber yield per acre on all types of soil.

(M.R.C.)

3. PRODUCTION AND GINNING PRACTICES AND FACILITIES.

In this section are discussed (1) production and ginning practices and facilities, cotton varieties, and insect pests and cotton diseases in the United States; and (2) production and ginning practices and facilities and cotton varieties in other cotton-producing countries.

THE UNITED STATES

Cultural Practices.—Because of variations in size of farms, topography, soil, climate, economic position of owners or operators, individual preferences and past experiences of farmers, and other factors, methods of cultivating cotton in the United States differ materially from area to area and from farm to farm. There are differences in the farm machinery used, crop rotation, width of rows, spacing of plants in the rows, type and amount of fertilizer used, frequency of hoeing and cultivating, varieties grown, and insect and disease control practices. On some farms, particularly in hilly sections, and on some plantations where tenants and sharecroppers are employed, all cultivating may still be done with one-horse, half-row equipment requiring a great deal of man-labor and horse-work per acre. On other farms almost all operations, including harvesting, may be done with large-scale mechanical equipment. On the high plains of Texas and in some of the coastal plains areas, in the Mississippi Delta, and in the irrigated areas of the Far West, cultivation on a good many farms is performed with four-row equipment requiring comparatively few man-hours, machine-hours, and tractor-hours.

Irrespective of the exact procedures followed, there are several operations common to most farms and most areas of the cotton belt. These include preparation of the seedbed, planting, chopping or hoeing (including thinning), and cultivation and hoeing of the growing plant. On many farms, especially east of the Mississippi, the application of commercial fertilizers is an-

other major operation involved in producing a crop. Also important in the humid areas are the practices followed in combating insect pests and diseases.

After the cotton is harvested, the land may be planted to legumes or some other crop in the late fall or early winter, but usually it remains idle until the following spring. In fact, some cotton may not be harvested until December or even January, although about 90 to 95 per cent of the crop is normally ginned by December 1. Whether or not the land is put to use shortly after the crop is harvested, the cottonstalks, especially if they are of any considerable size, are usually crushed with a stalk cutter or by some other method before the operator is ready to prepare the land for the new crop. In areas where stalks make a very limited growth, no cutting is necessary before the initial breaking or plowing of the land.

Planting normally begins early in March in the extreme southern part of the cotton belt, and about the middle of May in its northern limits. In a given area most of the planting is completed within a period of one month. In all sections of the belt, planting is done in rows, the seed being either drilled in or dropped in hills, which are usually 8 to 20 inches apart. The operation is performed by planters varying from one-row, horse-drawn types to four-row equipment that is usually drawn by a tractor. In drilling, the planter is ordinarily adjusted so that the seed is spread more or less continuously with little or no space between the individual seeds. In this case, the plants are usually chopped—that is, cut out with a hoe—leaving one or more plants per hill. Depending on the weather, soil condition, time required for the plants to reach a height of two to four inches, and availability of labor, chopping is customarily done within three to five weeks after planting. Many farmers plant the cotton in hills in order to reduce the amount of hoeing required, even though hoeing and thinning are practiced. If the season is unfavorable and the seed has grown to an unsatisfactory stand, replanting is often necessary.

After chopping, the cotton is usually cultivated in order to keep down grass and weeds and maintain the proper condition of the soil. It may then be necessary to hoe the cotton once or twice to keep the grass and weeds under control; in this case, the crop is cultivated shortly after being hoed. Where hoeing is unnecessary, the crop is generally cultivated at least once or twice, and sometimes three or four times, after the cotton has been chopped or otherwise thinned. The final cultivation prior to harvesting, often called "laying by the crop," usually occurs some four to six weeks before harvesting begins. This is about July 1 in the extreme southern states of the belt and early in September in its upper limits.

To a limited extent in some level areas, cotton is cross-cultivated, the plants being spaced at uniform intervals equal to the width of the rows. This practice greatly reduces and sometimes eliminates hoeing. Cross-cultivated cotton may either be planted in hills at the desired intervals or drilled in and thinned by plowing out the surplus plants.

Harvesting.—A very large percentage of the United States cotton crop is hand picked, the seed cotton being picked from the open boll. Another method, called hand snapping or pulling, has been used for some years in parts of Texas

and Oklahoma and to a very limited extent elsewhere. This process involves snapping or pulling the entire bolls instead of picking the locks of cotton and leaving the burrs on the plants.

After years of experimentation, mechanical harvesters are being used to an increasing extent. They are of two general types: one which strips off the bolls, leaves, and a certain amount of stems, and one which picks the lint from the open boll. There is considerable optimism among manufacturers of mechanical harvesters and others regarding the increased production and sale of such machines. They expect that, especially on large farms and plantations, such as those in the Mississippi Delta, the high plains and coastal plains of Oklahoma and Texas, and irrigated areas, most cotton harvesting will eventually be performed by some type of machine requiring very little man-labor. Since chopping and harvesting normally constitute a very large percentage of the labor required to produce cotton, the use of a successful mechanical harvester reduces the cost of cotton production. In the early stages of development, however, the lowering of the grade of cotton, and consequently its value, has been a problem.

Use of a mechanical harvester is often accompanied by a great reduction, and sometimes complete elimination, of hand chopping and hoeing. This is accomplished through cross-cultivation, mechanical choppers, and flame cultivators. There are several types of mechanical choppers in use on either a commercial or an experimental basis which, combined with a successful harvester, greatly reduce the man-labor required in producing cotton. Furthermore, the use of successful machines for the two operations is usually accompanied by greater mechanization of other cotton production operations.

An indication of the possible reduction in harvesting costs through the use of mechanical harvesters was given in a report released by the Texas Agricultural Experiment Station and the United States Department of Agriculture in 1951, based on tests conducted in the high plains cotton area of Texas in 1949. These tests showed that usual hand harvesting charges would have to be reduced about 50 per cent in order to make them competitive with mechanical stripper costs when computed on the basis of an operation involving 150 acres of cotton. These estimates included allowances for differences in the quality and value of the cotton and differences in ginning costs. The stripper type of harvester, however, is not nearly so well adapted to many parts of the cotton belt as it is to the area in which these tests were conducted.

Another study, made by the University of California and the Department of Agriculture, gave the results of the use of 63 mechanical pickers by farmers in California in 1949. It showed that the average total harvesting cost plus the value of the cotton lost in the field (as compared with hand picking) and the loss in grade equaled \$26.17 per bale. This compared with hand-picking costs of \$45.00 per bale.

Studies made in the Mississippi Delta have not shown the mechanical picker to be nearly so much more economical than hand picking, due to operation for far fewer days, smaller numbers of bales harvested per machine, and greater field waste.

Ginning and Packaging.—In addition to separation of the fiber from the seed, cotton ginning

Table 1—DESCRIPTION OF UNITED STATES COTTON BALES

Kind of bale	Approximate dimensions (in inches)	Gross weight (approximate)		Ties per bale	
		Pounds per bale	Pounds per cubic foot	Usual number	Usual weight in pounds
Square, flat, gin, or uncompressed	56x28x45-48	500	12-14	6	
Standard or railway-compressed	56x30x22	500	22-30	8	
High-density	57x22x22	500	32-35	9	
Round	35 long; 22 in diameter	250	30-33	0	

includes cleaning and other preliminary processes involved in preparing seed cotton. Harvested cotton usually contains dirt, hulls, leaf fragments, and other materials which must be removed if the ginned lint is to have a high market value. Even with the most elaborate gin machinery, however, it is impossible to produce from roughly harvested seed cotton lint equal in quality to lint from carefully picked cotton. Moreover, many gins in the United States are still not equipped with improved cleaners and extractors. This factor, together with the differences in market value between low-grade and high-grade cotton, has retarded the use of mechanical harvesters.

Almost all the cotton produced in the United States is ginned on saw gins, the use of roller gins being confined to the small quantity of American Egyptian and Sea Island cotton produced. The modern gin used in the United States is highly efficient and is almost automatic, the whole operation involving a minimum of man-labor. From the time the cotton leaves the farmer's wagon or truck, from which it is sucked by air, until it is ginned and packaged in the form of a bale, it is scarcely touched by hands.

After the seed cotton has passed through the cleaning machines, it is fed through a lint flue into a condenser, which separates the lint from the air. The lint is usually delivered from the condenser by mechanical means into a press box where (in the case of the so-called square or flat bale) it is pressed down slightly by a mechanical trampler. The press box is located over the ram of the press, which rises from below and presses the cotton into bales. The bales are then covered with approximately six yards of bagging, which is usually made of jute, though sometimes of cotton, and are tied with metal bands called ties. The bagging used to cover the square or flat bale weighs 1.75 to 2 pounds per linear yard. After a bale has been sampled, one or two patches, weighing 3 or 4 pounds each, are frequently added. Tare (which includes bagging, patches, and ties) may under Southern mill rules total as much as 22 pounds per square bale and 24 pounds per compressed bale; under New England rules, as much as 24 pounds per 500-pound bale.

Over the years, about 98 per cent of each crop has been packaged in square bales and about 2 per cent in round bales. The square or flat bale is actually rectangular, measuring approximately 56 by 28 by 45 to 48 inches. In general, the gross weight of the square bales produced in the United States ranges from 480 to 530 pounds and averages somewhat more than 500 pounds. Additional compression of the square gin bales produces standard or railway-compressed bales and high-density bales. The dimensions, weight, and ties used for the various types of United States cotton bales are shown in Table 1.

The packaging of United States cotton has

never been wholly satisfactory. In fact, United States cotton has been characterized as one of the most unsatisfactorily packaged commodities entering the channels of world trade. Although the methods of preparing most other United States commodities for market have undergone continual improvement, cotton is still baled in about the same way as it was before the Civil War. The principal defects of the United States bale are (1) its ragged and unattractive appearance, (2) the inadequate protection afforded by the bagging materials, (3) the lack of even approximate uniformity in weight of bales and weight of tare, and (4) the excess weight of the covering materials (especially in the case of compressed bales containing one or two patches). This situation places United States cotton at a disadvantage in world markets (where it competes with the neater packages of other cotton-producing countries), increases marketing costs, and complicates trading practices.

Closely related to the packaging of cotton is the question of identification of individual bales. For many years methods of marking have been inadequate to preserve the identity of the bales after they have left the gins and until they reach the place of consumption. This factor sometimes contributes to careless or irregular practices on the part of growers, ginners, and others handling cotton, and thus handicaps the efficient functioning of the marketing system.

The Department of Agriculture has conducted experiments, sponsored demonstrations, and subsidized the use of improved bale coverings in an effort to improve the packaging of United States cotton. It is generally believed, however, that, under the existing system of gross-weight trading practices in the United States, important progress in the improvement of bale covers cannot be expected unless the government makes more desirable types of bagging available at below-market prices.

Cotton Varieties.—By 1936 more than 1,200 cotton varieties and strains had been listed by name as growing in the United States. Many of these so-called varieties, however, were merely synonyms or new names applied to the same stock by different growers. In the census report of 1880, 58 varieties were listed, but by 1925 only 25 of those listed in 1907 were in existence and only 9 were cultivated extensively. Despite the extent to which varieties, at least by name, come and go, there are a few lines which seem to be continuous. The history of the leading varieties of the early 1950's covers a considerable period—a period which would doubtless be much longer if earlier records had been kept.

In the early 1930's a committee of plant breeders and agronomists of the Association of Agricultural Workers (affiliated with the American Society of Agronomy) began the selection of certain typical varieties of the cotton belt for use

as standards in future breeding. The committee chose 31 typical varieties, many of which were represented by several strains. The list was published in the *Journal of the American Society of Agronomy*, January 1936, as follows:

Acala-5	Kasch
Acala-8	Half and Half
New Boykin	Lone Star
Cleveland-5	Mebane
Cleveland-884	Missdel
Piedmont Cleveland	Station Miller
Wannamaker Cleveland	Mexican Big Boll
Cook 307-6	Oklahoma Triumph-44
Delfos	Pima
Delta & Pine Land-8	Rowden
Delta & Pine Land-10	Arkansas Rowden-40
Deltatype Webber	Toole
Dixie Triumph	Stoneville
Dixie-14	Trice
Express-121	Wilds
Lightning Express	

No comparable list was prepared after World War II, but information on the most important varieties in use in 1952 indicated that at least one third of the 31 varieties had been discarded.

Since the early 1930's much has been done to encourage United States farmers to use improved and better-adapted varieties of cotton. The most important development of this nature has been the adoption and use of single varieties in numerous communities throughout the cotton belt. Active cooperation between the Department of Agriculture and affiliated state and other agencies to encourage the establishment of one-variety communities began in December 1930. By 1932 there were approximately 75 one-variety community units in operation from North Carolina to Texas, harvesting more than 2,000 acres of cotton that year. In addition, about 400,000 acres in the Southwest and an undetermined acreage in many other areas not specifically affiliated with the Department of Agriculture's program were devoted to the planting of one kind of cotton. In 1942 there were 2,563 one-variety communities, with a membership of 291,860 participating farmers and a planted area of 6,613,533 acres. While the participating farmers comprised a comparatively small percentage of the cotton producers of the United States, their acreage in cotton amounted to 28 per cent of the nation's total and represented a marked increase during the preceding decade. By 1950 the number of active one-variety community units had declined, largely as a result of consolidations, to 2,066, but the number of producers involved totaled 340,000 and the planted area had increased to 7,162,000 acres.

Because of larger yields per acre and a better average quality of cotton, the use of the improved varieties has materially increased the cash income received by the grower-members of the one-variety communities. The large areas standardized on superior varieties of upland cotton provide relatively large, even-running lots of cotton mostly of medium and long staple, and thereby contribute to more efficient marketing. When only one variety is produced in a given area, the mixing of seed at the gin, which generally occurs in areas where several varieties are grown, is avoided.

In 1944 a very large part of the acreage in one-variety communities was devoted to five variety types: Stoneville, Delta & Pine Land, Coker-100, Acala, and Mebane. While many other variety types were being grown either in one-variety communities or elsewhere in the cotton belt in 1952, larger acreages were probably

devoted to these types than to all others combined.

Insect Pests.—From the beginning of cotton culture on the North American continent, growers have had to contend with insect pests. In the mid-19th century and earlier, losses from insect pests were caused largely by the cotton worm, bollworm, and cotton aphid. These insects are still important, but they have been overshadowed by the boll weevil, cotton flea hopper, and pink bollworm. In most years the reductions in cotton yields per acre as a result of the boll weevil are considerably larger than those from all other cotton insect pests combined. The Bureau of Agricultural Economics estimated that during the period 1945-1949 the reduction from full yield due to the boll weevil was 10.7 per cent, as compared with an estimated reduction of 1.5 per cent due to all other insect pests.

Because of variations in climatic and other conditions, cotton insect problems differ materially from one area to another. In fact, at times the problems in two adjoining counties or on two adjoining farms may be strikingly different and require different measures of control.

All cotton pests can be controlled to some extent by cultural practices. Such factors as varieties, time of planting, spacing, methods of cultivation, crop rotation, and quantity and type of fertilizers used may each directly or indirectly affect the damage done by certain insect pests and their control. In addition, such natural factors as winter and summer temperatures, rainfall, and the number of clear days have important effects on the amount of damage done by insect pests. Furthermore, the numbers of most, if not all, cotton insects are reduced to some extent by predaceous and parasitic insects, spiders, and birds. An important means of controlling insect pests is a quarantine to limit their spread through shipments of cotton, cottonseed, or other vegetable matter. Quarantines have been effective in limiting the spread of the pink bollworm and the *Thurberia weevil*. Perhaps the principal man-made control measure, particularly from the standpoint of reducing losses in any individual year, however, is the use of insecticides. Recommendations concerning insecticides and other methods of controlling 10 important injurious cotton insects, together with other information on these insects, are summarized in Table 2.

Cotton Diseases.—Cotton is attacked by many fungus, bacterial, and physiological diseases, causing annual losses in the United States crop aggregating millions of dollars. The major diseases affecting cotton grown in the United States, in the approximate order of their importance, are root rot, fusarium wilt, bacterial blight, root knot, rust, anthracnose, and verticillium wilt.

Root Rot.—Root rot, caused by the fungus *Phymatotrichum omnivorum*, is the most important cotton disease in the Southwestern states. The greatest damage occurs in Texas, especially in the heavy black-wax soils. By attacking and destroying the root system, the fungus causes sudden wilting and death of the plants. Its growth in the soil is entirely subterranean except when it is producing fruiting bodies. Since the fungus persists for many years in the soil and all varieties of commercial cotton seem to be equally susceptible to the disease, control measures are difficult. It has been demonstrated, however, that damage from the disease can be greatly reduced by crop rotations, good tillage practices, and the maintenance of a high state of fertility.

Table 2—CONDENSED INFORMATION ON 10 IMPORTANT COTTON INSECTS IN THE UNITED STATES

Common name of insect	Scientific name of insect	Probable native home	Distribution in United States	Nature of injury	Crops other than cotton attacked	Control measures recommended to the late 1940's ¹
Boll weevil	<i>Anthonomus grandis</i> Boheman	Mexico and Central America	Texas, Oklahoma, and all cotton states east of them	Causes shedding by feeding on squares and bolls. Grubs feed on seed and lint in green bolls.	None	Dust at 5-day intervals with calcium arsenate, when from 10 to 25 per cent of the squares are punctured, using 5 to 7 pounds per acre. Destroy stalks early in fall. Practice good culture.
Bollworm	<i>Heliothis erinigera</i> Hübner	Tropical and subtropical America	General	Destroys squares and bolls by eating into them.	Corn, tomatoes, beans, etc.	Dust with cryolite, lead arsenate, or calcium arsenate at the rate of 8 to 10 pounds per acre. Plow in fall and winter to destroy pupae in soil.
Cotton worm	<i>Alabama argyria</i> Lecles Hübner	Mexico, Central America, and South America	May appear at irregular intervals, anywhere in cotton belt through migration of the moths from countries south of the United States.	Defoliates plants.	None	Dust or spray with calcium arsenate or other arsenical poison.
Cotton flea hopper	<i>Psalidium teridius</i> Reuter	United States	General	Makes feeding punctures that cause small squares to shed.	None	Destroy goatweed, horsemint, and other weeds in winter. Dust with 12 to 18 pounds of finely ground dusting sulphur, or with 12 to 15 pounds of a mixture of 2 parts of sulphur and 1 part of calcium arsenate, per acre. If boll weevils are present, use the mixture of sulphur and calcium arsenate.
Tarnished plant bug	<i>Lygus pratensis</i> Linnaeus	Europe	General	Makes feeding punctures that cause squares to shed.	Many	Dust at the rate of 12 to 15 pounds per acre with a mixture of 2 parts of sulphur and 1 part of calcium arsenate, or a mixture of 12 parts of sulphur to 1 part of paris green.
Rapid plant bug	<i>Adelphocoris rapidae</i> Say	United States	General	Makes feeding punctures that cause squares and small bolls to shed.	Many	Same as for tarnished plant bug.
Common red spider	<i>Tetranychus telarius</i> Linnaeus	Unknown	General	Sucks plant juices, causes shedding of leaves.	Many	Keep down weeds near cotton fields. Dust with finely ground sulphur, 10 pounds per acre.
Cotton aphid	<i>Aphis gossypii</i> Clover	Northern Hemisphere	General	Sucks plant juices, stunts plants, causes leaves to curl and fall. Gives off honeydew that injures fiber in open bolls.	Melons, squash, cucumbers, okra, etc.	Dust with 2.5 per cent of nicotine prepared by mixing 6¼ pounds (5 pints) of nicotine sulphate with 100 pounds of hydrated lime or with calcium arsenate if boll weevils are also to be controlled.
Pink bollworm	<i>Pectinophora gossypiella</i> Saunders	India	Limited areas in Arizona, New Mexico, Texas, Florida, and Oklahoma	Reduces quality and quantity of seed and lint by feeding of worm.	None	Quarantines protect uninfested areas. Sterilize seed by heating. Destroy gin trash. Pick cotton early and destroy stalks. Pasture fields after picking. Plow deeply and irrigate if practicable.
Cotton leaf perforator	<i>Bucculatrix thurberella</i> Busck	Mexico or southwestern United States	Abundant only on southern borders of California and Arizona	Skeletonizes leaves.	None	Dust with powdered lead arsenate, 5 to 7 pounds per acre. Destroy old plants. Plant cotton annually on well-prepared land.

¹ Since the late 1940's, there have been so many effective insecticides under investigation that federal, state, and private entomologists have met each year and prepared revised recommendations for the control of cotton insects during the coming year. These recommendations may be obtained from the United States Department of Agriculture.

These measures are more effective when properly combined. The more effective rotations include grain crops and winter or summer legumes, and regularly involve fall plowing. Nitrogen, supplied by barnyard manure or by turning under legumes, is especially beneficial, although heavy applications of inorganic nitrogen are usually helpful.

Fusarium Wilt.—This disease, caused by the fungus *Fusarium vasinfectum*, is found in many types of soil from Virginia to New Mexico. Wilt-infected plants appear dwarfed fairly early in the season, the leaves become yellow between the veins, and sections of the stems and roots are black, giving rise to the common name "black rot." The fungus enters the roots of the plant from the soil, and its growth produces in the tissues toxins which finally accumulate in sufficient quantity to cause wilting and, eventually, death of the plant. In combating fusarium wilt, growers should use wilt-resistant varieties of cotton in combination with crop rotation, fertilize the plants liberally with high-grade balanced fertilizers, and maintain adequate vegetable matter in the soil by adding manure or by plowing under cover crops.

Bacterial Blight.—Also known as black arm and angular leaf spot, this blight is caused by the organism *Xanthomonas malvacearum* and occurs generally throughout the South and also in the Southwestern cotton districts. The principal injurious effects are stunting or death of seedlings, defoliation of plants, shedding of buds, and rotting of bolls. Damage is often especially severe after windstorms and during cold, wet weather, for the disease is spread chiefly by wind-blown rain. Experiments have shown that the disease is largely seedborne and may be controlled effectively by seed treatment. The use of resistant varieties is also recommended.

Root Knot.—This disease is caused by minute eelworms or nematodes (*Heterodera marioni*) which bore into the roots and produce galls or abnormal swellings. It affects cotton and many other plants in almost every state in the cotton belt but, like wilt, is most severe in sandy soils of low water-holding capacity. Root knot causes swellings, nodules, and discoloration of the roots and stunts the growth of the plants by cutting off the supply of food and water. It is disseminated by drainage water, cultivating implements, infected plant roots, or any agent carrying soil particles. In cotton districts where the disease is unusually prevalent, rotation with such non-susceptible crops as winter grains or resistant summer legumes for two or three years in succession is the only effective control measure so far developed. On heavily infested soil the planting of very susceptible varieties of cotton should be avoided.

Rust.—"Potash hunger" or rust is a physiological disorder of the cotton plant prevalent in soils of low fertility, especially those deficient in vegetable matter and available potash. Plants affected by rust fail to attain normal growth and lack a healthy green color. Later the entire leaf becomes somewhat blackened, curled, and ragged and then sheds, leaving the stalk bare. Since most of the leaves are shed prematurely, the bolls do not develop properly and the lint is of inferior quality. Rust may be satisfactorily controlled by liberal applications of potash or potash-containing fertilizers, preferably in conjunction with the growing and plowing under of

green-manure crops, or by adding barnyard manure.

Anthraxnose.—This disease, caused by the fungus *Glomerella gossypii*, does much damage to cotton in the Southeastern states. Where cotton grows rank, boll rot, often called pink boll rot, may become common. The greatest loss from anthracnose, however, occurs in the seedling stage, when the disease is spoken of as "damping off" or "seedling blight." The loss of stands, often necessitating replanting, is likely to occur in cold, wet springs. Since the disease is disseminated largely through infected seed, it may be controlled by using seed with a minimum of infection and by treating the seed with fungicidal dusts.

Verticillium Wilt.—The symptoms of plants infected with this disease, caused by the fungus *Verticillium albo-atrum*, and of those infected with fusarium wilt are very similar. Verticillium wilt occurs commonly in the neutral to alkaline soils from Mississippi to California, whereas fusarium wilt predominates in the more acid soils of the Southeast. Commercial varieties differ greatly in their susceptibility to verticillium wilt, and very susceptible varieties should not be planted in heavily infested soils.

OTHER COTTON-PRODUCING COUNTRIES

Cultural Practices and Harvesting.—Because of wide variations in soil and climate, background of producers, ability of producers to obtain improved farm machinery, and income and general economic status of growers, cotton cultural practices outside the United States differ to an even greater extent than those within the United States. In parts of China, India, Pakistan, Egypt, the Anglo-Egyptian Sudan, Nigeria, Uganda, Kenya, Tanganyika, the Belgian Congo, Angola, Northern Rhodesia, Southern Rhodesia, Mozambique, Brazil, Peru, and some other cotton-producing countries and territories, cotton is cultivated with very primitive implements. In China, as in some parts of other countries, the seed is sown broadcast and is given very little cultivation, with the result that the plants grow up thickly, develop poorly, and yield only small quantities of poor-quality cotton. In certain districts of Brazil, Argentina, Peru, Mexico, the Soviet Union, Egypt, India, and Pakistan, and to a more limited extent in other countries, cultural practices and farm implements used compare favorably with those employed by some cotton producers in the United States.

In several countries mechanical harvesters have been used at least on an experimental scale, but a very large part of the cotton is hand picked. With few exceptions, hand snapping, sledging, and mechanical picking have not been employed even to the limited extent that these methods have been used in the United States.

Ginning and Packaging.—In India and Pakistan a small amount of cotton is still ginned on the charkha, a primitive machine which is worked by hand and has an output of about five pounds of lint per day, but the bulk of the ginning is done on modern power-driven roller gins. Saw gins are used to some extent in the Punjab and other areas where American upland cotton is grown. In parts of China ginning is also done with primitive machines, although there are few, if any, countries which do not have at least some modern power-driven gins. Cotton of Egyptian and Sea Island types (*G. barbadense*)—as well

as American Egyptian cotton in the United States—is ginned largely on power-operated roller gins. Such gins give much better results with these types of cotton than do the saw gins used most commonly throughout the world on upland cottons (*G. hirsutum*). A large part of the cotton produced in Brazil, Argentina, Mexico, and other countries is ginned on saw gins similar to those used in the United States, where, in fact, many of the gins in these countries were manufactured.

In Egypt the baling system is entirely different from that in most other countries, bales from interior ginneries being remade at the compresses in Alexandria. The Egyptian bale weighs about 750 pounds net. It has a density of about 35 pounds per cubic foot and a tare equivalent to about 2 per cent of the total weight. In India and Pakistan bales usually weigh about 400 pounds, although some designed for export weigh 500 pounds, and the density is about the same as that of Egyptian bales. In most British colonies bales weigh about 400 pounds, but in some of the colonies and in other areas producing small quantities cotton is sometimes packaged in bales weighing only 200 to 300 pounds.

Cotton Varieties.—Improvements in cotton varieties in the modern sense may not be much older in other cotton-producing countries than they are in the United States. Many centuries ago, however, some crude form of seed sorting or selecting may have accelerated the adoption of wild forms of cotton to domestication in areas where the cotton plant was native.

India and Pakistan.—In the Indian subcontinent, which is perhaps the oldest cotton-growing area in the world, the native cotton, so far as is known, has always been very short in staple and much of the work in breeding and improvement has been concentrated on the development of better staple. Most of this work, which also includes efforts to obtain higher ginning output, better yields, and greater disease resistance, has been done in states and provinces where short-staple cottons are chiefly grown. Considerable progress in improving cotton varieties has been made through various crosses and the introduction of American upland stock.

Read P. Dunn, Jr., in *Cotton in Pakistan and the Indian Union* (see *Bibliography*), reported on the proportions of the various cotton varieties in the 1947-1948 crop, as shown in Table 3. From this it is seen that American upland varieties then accounted for about 9 per cent of the cotton crop of India and Pakistan; *Arboreum* types, which are indigenous to India, for nearly 57 per cent; and the *Herbaceum* group, originally introduced from Africa, for 34 per cent.

China.—In China, which long ranked as the second largest producing country, much improvement was made before World War II in the varieties grown. In 1915 the University of Nanking began experiments in cotton growing and demonstrated the practicability of growing American upland cotton in several parts of the country. Several standard sets of cotton seed, representing widely different types of American upland varieties, were obtained from the United States Department of Agriculture in 1919, and tests were conducted in 26 centers, mostly mission stations. About this time it was reported that Acala and Trice were two American upland varieties which were quite well adapted to certain areas, while in other areas native varieties are said to have given better results. From then

Table 3—COTTON VARIETIES IN INDIA AND PAKISTAN

Botanical class and variety	Estimated percentage of 1947-1948 crop
Bengals, comillas	7.3
Oomras	12.1
Malvi, Garoni, Mathia	8.5
Karunganni, Northern, Cocanada, Uppam, Tinnevely, Mungari	5.2
Jarila, Verum	23.6
Total, <i>Arboreum</i> (Asiatic)	56.7
Dholleras, Wagad	9.8
Broach, Vijay	11.3
Surti	4.9
Jayawant	2.6
Western Farm	5.6
Total, <i>Herbaceum</i> (Asiatic)	34.2

LSS, 4F	1.3
Perso-American, Mall, etc.	.1
Total, <i>Hirsutum</i> (American upland)	9.1

until the Japanese invaded China in 1937, the percentage of American upland varieties increased greatly. Relatively little is known about the cotton situation in China during and since World War II.

Egypt.—Since 1905, when Egyptian growers began using modern plant-breeding methods, several important varieties of cotton have been developed and produced exclusively in Egypt. In its official reports and estimates, the Egyptian Ministry of Agriculture groups the various varieties into three categories: long staple, which is approximately $1\frac{1}{8}$ inches and longer; medium staple, $\frac{1}{4}$ to $1\frac{1}{32}$ inches; and short staple, about $1\frac{1}{8}$ to $1\frac{1}{32}$ inches. These terms differ from similar terms used in the United States, since the Egyptian varieties referred to as short staple produce staples, many of which are $1\frac{1}{8}$ inches and longer, which are generally called long staples in the United States. As of 1950-1951, the principal varieties of Egyptian cotton were as follows:

Long staple	Medium staple	Short staple
Karnak	Giza-30	Ashmūni
Menoufi (Minūfi)	Giza-23	Zagora

Soviet Union.—In the last quarter of the 19th century, Russian cotton growers began to replace short Old World cottons with American upland varieties. After the revolution of 1917, new varieties developed by Russian plant breeders were introduced on a commercial scale and soon became widely used. Cotton breeding and improvement received considerable impetus in the 1930's. About 1935 the variety called Navrotsky, developed by E. L. Navrotsky from the American upland variety of Russell, was estimated to account for about 75 per cent of Soviet cotton production. Strains of King, Mebane Triumph, and others had also been adapted and were in use by that date. Relatively small acreages of cotton were planted to varieties of Egyptian origin. Little authentic information has been available about cotton varieties in the Soviet Union since 1939.

Brazil.—The Russell variety of Truitt origin, which was developed in the United States in 1895, was apparently introduced into Brazil shortly thereafter, and it became the basic stock for much of the upland cotton of southern Brazil. Other upland varieties imported by Brazil include

Sunbeam, Upright, Express Cleveland, Durango, and Webber. In northeastern Brazil these varieties became hybridized and mixed among themselves, and some were crossed with native tree cottons. Since the early 1930's the Brazilian federal government and the various state governments have been active in the improvement of Brazilian cotton, and government control of seed distribution has been instituted. As a result, a very large percentage of the cotton grown in Brazil is of American upland origin.

Peru.—The cotton industry in Peru was made possible largely by introducing and breeding new varieties. The most important contribution to plant breeding by the Peruvian cotton industry was the development in 1918 of Tanguis, a wilt-resistant variety, from possible hybrids with previously imported stocks. Pima cotton, developed for the irrigated valleys of Arizona and California, was found to be adaptable to Peru as well. Of the 1942 Peruvian crop, it was estimated that 82 per cent consisted of Tanguis, with Pima ranking second. Peruvian Full-Rough, Peruvian Semi-Rough, American upland, and Egyptian each made up 1 per cent or less of the crop. In 1950, Tanguis and Pima still accounted for nearly all the Peruvian crop.

Argentina.—The cotton crop of Presidente Perón Province (formerly Chaco Territory), which in many years has accounted for 90 per cent or more of the total Argentine crop, consists of American upland varieties. Several of the leading varieties of United States cotton have been introduced and distributed to growers under government control. As a result of the work of local plant breeders under the National Cotton Board, both staple and yield have shown improvement. Because of its high quality and staple length, cotton grown in the Province of Santiago del Estero is used extensively by Argentine tire manufacturers. All or almost all of the Argentine crop is presumably of the upland type.

Mexico.—There is little information about cotton breeding in Mexico. Doubtless whatever improvement has been made is due largely to the selection of native varieties and the importation of improved varieties from the United States. Mexican commercial cottons are of the upland type. On the whole, the average staple length is apparently better than the average of the United States crop.

(M.R.C.)

4. MARKETING AND PRICES. In the United States the marketing of cotton generally begins after it has been ginned and baled. After the baled cotton has left the gin, it is sold by the producer, generally in a local market, to one of several types of buyers who may be located there. In most instances, this sale is only the first of many transactions involved in moving the cotton from the producer to the manufacturer. In areas adjacent to mills, the producer may sell his cotton directly to the mill buyer, but the great bulk of the United States crop passes through a succession of markets, which fall into four general types: (1) local, country, or primary markets; (2) central or concentration markets; (3) mill or spinners' markets; and (4) export markets.

A single market locality may have more than one marketing function and thus belong in two or more of these categories. Thus Houston, Texas, is important both as a central market and as an export market, and it may also serve as a local market for cotton grown nearby. A market like Gastonia, N. C., performs the functions of a local market, a central market, and a mill market.

The greater part of the United States cotton crop moves from the local market either to a compress or concentration point or to the ports, where it is compressed to standard or high density for shipment to United States mills, other central markets, or export markets. The cotton warehouse and the compress provide the owner with storage, which, with insurance, protects the cotton from weather, fire, and theft. The primary function of the compress, however, is to press the bale into a smaller, more compact package and thus make it possible to place a greater number of bales in a given space, such as a railway car, ship, or warehouse. Because of this saving in space, freight and storage rates are lower for a compressed bale than for an uncompressed bale, and if the cotton is to move very far it is generally compressed.

The flow of cotton from farm to mill involves a number of services connected with concentration, merchandising, and distribution. Estimates made in 1944 placed the spread between prices received by growers and those paid by manufacturers for cotton delivered to the mill at approximately \$10 per bale. The spread between the average price of Middling $1\frac{1}{16}$ -inch cotton in seven Texas and Oklahoma markets and the price landed at 201 mill points for the 1950-1951 marketing season was \$11.95 per bale. This spread, which represents that for the cotton belt as a whole and covers costs and profits connected with the various services, varies greatly in different producing areas and in different years. In those areas where the cotton is sold by the grower directly to the mills and where much larger quantities pass through the hands of a single buyer, the marketing spread is relatively low. In areas farthest from mill centers, and when specialty cottons are involved, the marketing spread is much larger than the average figure. In years when prices are high, the spread is much greater than when prices are low.

In addition to storage and compression, services involved in moving cotton from the farmer to the manufacturer include receiving and related services (issuance of warehouse receipts, sampling, weighing, marking or tagging, storage up to 30 days, and the like), insurance, transportation, financing, classing and assembly, risk bearing, overhead, and profits for those performing

these services. Of these, storage and insurance, financing, transportation, classing and assembling, and overhead are by far the most important and are estimated to account for 80 per cent or more of the total spread.

The owner or depositor of each bale of cotton placed in storage receives a negotiable warehouse receipt, identifying the individual bale and giving its weight. This receipt is readily accepted in marketing channels, and by its negotiation the ownership of the cotton passes from one buyer and seller to another. The importance of maintaining the identity of the individual bale is due to the variation in bale weights and, what is perhaps even more important, to the wide variation in the quality of cotton. One of the important services performed by cotton merchants in channeling cotton from the farmer to the manufacturer deals with quality.

Commercial Quality Classification.—As shown in the section on *The Cotton Plant*, the different species of cotton normally produce fibers varying greatly in staple length, which is one of the main factors determining the quality of cotton. Furthermore, because of differences in varieties, soils, rainfall, temperature, tillage methods, and harvesting and ginning practices, the quality of cotton of a given species may vary greatly. In fact, there are often considerable variations on a single farm where only one variety is grown. Cotton quality is important because it has a major bearing on the type and quality of the goods produced. In the main, the longer the staple length, the stronger is the yarn of a given size. Likewise, the higher the grade, the higher is the quality of the yarn and fabric and the smaller is the spinning waste. For these reasons, the prices paid for different types and qualities of cotton vary widely.

In general, cotton quality may be defined as the physical properties, characteristics, or attributes of cotton which affect its usefulness. The principal physical elements influencing the quality of cotton, thus defined, include (1) length, uniformity, fineness, strength, and maturity of the fibers; (2) color, leaf, and other foreign matter; and (3) ginning preparation of the cotton. Commercial quality classification or classing of cotton has been defined as the art and operation of systematically recognizing and identifying similarity in quality according to accepted scales of measurement by the use of consistent terms of description and by a consistent method. Although mechanical devices are available for determining many of the elements of cotton quality, they are not in general commercial use in buying and selling cotton, particularly in local markets. Thus far commercial classification of cotton has been made very largely by sight and touch.

In the marketing and distribution of United States cotton, quality is usually divided into three categories: grade, staple length, and character. Under authority contained in the Cotton Futures Act (1916) and the Cotton Standards Act (1923), official government standards have been established for the first two categories.

Grade.—Elements determining the grade of cotton include (1) color, (2) amount of foreign matter, and (3) ginning preparation. Color is influenced by the weathering or exposure to which the open cotton has been subjected, and by damage from insects and fungi both before and after the boll is opened. The color of the cotton has an important bearing on dyeing prop-

erties and, in turn, on the color and uniformity of the finished product.

Foreign matter includes dried and broken plant foliage of various kinds, seed coat fragments, motes, sand, and dust. The amount of such matter is determined largely by harvesting and weather conditions. These elements affect the appearance of the finished yarn and fabrics and the cost of processing the fiber.

Preparation is the term used to describe the degree of smoothness with which the lint has been ginned and the relative neppiness or neppiness of the ginned lint. In general, smoothly prepared cotton contains less waste and produces a smoother and more uniform yarn than roughly prepared cotton. Moreover, where preparation is poor as a result of neppiness, the finished yarn and fabrics may contain small visible dots or specks which have not been removed in the manufacturing process.

The official grade standards for American (United States-grown) cotton embrace 33 grades for upland, 5 full grades and 4 half grades for American Egyptian, and 6 full grades and 5 half grades for Sea Island. Most of the grades for upland cotton were promulgated by the secretary of agriculture on Aug. 29, 1935, effective on Aug. 20, 1936. Since these standards have been adopted by many of the leading cotton associations and exchanges of other countries, they are referred to as Universal Standards for American-Upland Cotton. These 33 grades of upland cotton are divided into 6 major color combinations: Extra White, White, Spotted, Tinged, Yellow Stained, and Gray. Within each color combination there are 3 to 9 different grades. The 9 White grades represent a very large part of the American upland crop. The terms Middling Fair, Strict Good Middling, Good Middling, Strict Middling, Middling, Strict Low Middling, Low Middling, Strict Good Ordinary, and Good Ordinary provide a scale from high to low for variation in color attributes within any major group, for variation in foreign matter, and for variation in ginning preparation.

Staple Length.—The staple length of cotton has been defined officially as "... the normal length by measurement, without regard to quality or value, of a typical portion of its fibers under a relative humidity of the atmosphere of 65 per cent and a temperature of 70 degrees Fahrenheit." As practiced by the cotton trade, commercial classification of staple length of United States cotton is determined by a process known as pulling the staple. This consists of repeated operations whereby small samples of cotton are drawn out and arrayed by the cotton classer, skillfully using the thumb and forefinger of each hand. By these procedures well-trained classers can determine the approximate staple length of the bulk of the fibers with a considerable degree of accuracy, when compared with either the pull of other classers or the length of staple as determined by mechanical means.

An order of the secretary of agriculture of Oct. 25, 1918, promulgated the standards for staple. As amended, this order provides for the designation of various lengths in terms of inches and fractions of an inch from less than $\frac{3}{4}$ inch upward, in gradations generally of $\frac{1}{32}$ inch to $1\frac{1}{4}$ inches, disregarding any fraction less than $\frac{1}{32}$. The order authorizes the issuance of practical forms of standards for some 20 individual lengths of upland cotton. Staple types for vari-

ous lengths of American Egyptian and Sea Island cottons are also available. In view of the absence of official standards for character, specialists in cotton standardization carefully select the bales to be used in preparing staple types so that they may be considered representative of cotton with normal character. When these staple types are properly pulled under standard conditions, the classer's pull will represent the length indicated on the standards package.

Character.—Character may be defined as those elements of cotton quality which are not part of grade or staple length. There are no character standards, although a number of the factors recognized as part of character are susceptible of measurement. Some of the more important of these elements are (1) strength, uniformity, fineness, and wall thickness of the fiber; (2) elasticity, pliability, and frictional properties; (3) fiber porosity; and (4) fiber durability. While measurements of several of these elements may be made, for the most part such measurements cannot be made sufficiently rapidly to be used generally in buying and selling transactions. Through experience, however, classers become familiar with certain cotton characteristics which will or will not give the desired spinning results.

Despite the development of a high degree of skill among classers, the classing of cotton for character is at best inexact. It is generally agreed that the manufacturing results obtained from cotton often do not confirm the classer's impression of the character of a given bale of cotton. Consequently, as improved laboratory techniques have become available, the use of such measurements in helping to determine the cottons best suited for manufacturing various types of yarns and fabrics has become quite extensive.

Spot Markets and Marketing Practices.—

Local Markets.—A local, primary, or country market is one in which the farmer sells his cotton. Most such markets have cotton gins, and sometimes there is little more than a gin at the market. In a local market the farmer usually sells to one of several types of buyers: (1) ginners; (2) local independent cotton merchants, including individuals or firms engaged primarily in other businesses; (3) representatives of farmer cooperative associations; (4) traveling or resident representatives of large cotton merchants whose headquarters are located in other markets; (5) traveling or resident buyers for cotton mills; and (6) commission men or factors. The number of buyers in a single market varies from 1 to 20 or more.

These markets represent the first step in the movement of cotton from the grower to the ultimate consumer. They are found in almost every village and town and in many cities of the cotton-producing area of the United States. The annual volume of cotton sold in a single market varies from a few hundred bales at country gins and at crossroads stores to many thousand bales in larger towns and cities.

In local markets cotton is sold by the farmer to buyers who may or may not be qualified to determine quality. This is true despite the fact that differences in the quality received in a given market on a given day may be sufficient to account for variations in the value of the cotton, as quoted in central markets, ranging up to several cents a pound. Most farmers know very little about the exact quality of their cotton. The general level of knowledge has increased,

however, and the system of buying commonly referred to as "hog round," where there is little or no variation in price because of differences in quality, has declined. This system is considered to be a handicap to the efforts of government agencies to improve the quality of cotton being grown. Very often varieties producing a lower quality give higher yields per acre than those producing a higher quality, and returns received from this cotton may therefore equal or exceed those from cotton of better quality. Studies made by the Department of Agriculture indicate, however, that even in markets of this type average prices received by all growers are generally influenced by the average quality of the cotton sold in the particular market.

The Department of Agriculture attempts not only to determine the marketing practices existing in the various local markets throughout the cotton belt and the effect of these practices on prices and quality improvement, but also to encourage the sale of cotton on the basis of each individual bale's grade and staple. For many years the department has provided various market news services designed to give growers more information on central market prices for various qualities of cotton. Since 1938 free government classification of cotton has been furnished for an increasing proportion of the cotton crop so that growers may know the quality of their cotton. This service, together with information on central market quotations, offers growers a means of determining whether or not local buyers are paying a fair value for the cotton being sold.

Most local markets have a public square, a cotton yard, a warehouse, or a railroad platform where the cotton is received, weighed, and sampled, and where receipts are issued. In some markets sales may be based on inspection of the cotton while it is in the yard or on a railroad platform; in others sales may be based on samples, receipts being obtained at the yard or warehouse. Markets of this type furnish a ready and convenient place where growers may sell at almost any time. They also provide a point for assembling sufficient quantities to facilitate handling.

United States farmers usually sell their cotton soon after it has been ginned. In limited areas, particularly in sections of the northern part of the cotton belt, a proportion of the crop is sold as seed cotton. On the average, 90 to 95 per cent of the United States crop is ginned during the first four months of the season. Sample studies indicate that about seven tenths of it is sold by growers during this four-month period, and that in 1936-1937 a little more than half the cotton was sold on the same day that it was ginned, more than seven tenths within 2 days, and about seven eighths within 10 days after it had been ginned. In general, the situation probably has not changed materially since these studies were made, except in years when prices are about the same as, or below, government loan rates. Then substantial proportions of the crop may go under government loan and smaller proportions are sold as soon as the cotton has been ginned.

Since a large part of the crop is grown by farmers who produce only a few bales and take only one or two bales to the gin at a time, most sales are made in small lots. The sale is usually for cash, and delivery is made immediately. Soon after the cotton has been purchased, the local buyers usually resell it to shippers for

immediate delivery. As a general rule, farmers and small buyers do not hedge their cotton, but sell promptly and so transfer to larger dealers the risks from price changes. To a very limited extent, however, farmers in some parts of the cotton belt sell at least part of their cotton for forward delivery at a price to be fixed at a later date.

Central and Export Markets.—Central or concentration markets are those in cities and larger towns where cotton from the local markets is concentrated for distribution to consuming centers either in the United States or in other countries. Central markets which are important in the export business may also be classed as export markets. Among the personnel of central and export markets are general cotton merchants, spot brokers, factors, growers' cooperative associations, and mill buyers. Cotton merchants include those who buy mainly in local markets and sell either to domestic spinners or to foreign importers or spinners. Spot brokers sell cotton on commission, chiefly for dealers in interior markets but to some extent also for local holders in central markets, based mainly on samples displayed on tables in salesrooms. Some brokers also buy on commission for foreign importers and spinners. The factor receives cotton on consignment from the owner (to whom he may or may not have advanced funds) and sells it in accordance with the owner's instructions. Growers' cooperative associations merchandise cotton for growers in a way similar to that followed by merchants who buy in the interior.

Facilities in central markets generally include a cotton exchange, which is the center of activity in the market, as well as offices and sample rooms, compresses, warehouses, and freight terminals. At ports there are also steamship docks. The exchanges enforce rules to ensure fair practices in trading and compile statistics on receipts, stocks, shipments, and prices. In addition, there are banks which supply funds for financing the buying and holding of cotton.

These markets are located at interior points and ports favorably situated for assembling and distributing cotton. Those in the interior include such markets as Dallas, Little Rock, Memphis, Montgomery, and Atlanta, and those at ports include Houston, New Orleans, Mobile, and Savannah. A large part of the United States crop is usually concentrated in and distributed from central markets, although considerable cotton moves directly from local markets and smaller interior concentration points to domestic mills.

Mill or Spinners' Markets.—These markets are places where cotton is purchased by and sold to buyers representing cotton spinners. They are generally located near mill centers, but also include all central markets. Some of the important mill markets in New England include Boston, New Bedford, Fall River, and Providence. In North Carolina such markets include Greensboro, Gastonia, and Charlotte; in South Carolina, Spartanburg and Greenville; in Georgia, Atlanta and Augusta; in Alabama, Huntsville.

Important spinners' markets for United States cotton in other countries before World War II included Liverpool and Manchester, England; Rouen, Lille, Spinal, and Mulhouse, France; Ghent, Belgium; Chemnitz, Munich, and Rhine, Germany; Oporto, Portugal; Rotterdam, Netherlands; Milan, Italy; Barcelona, Spain; Osaka, Japan; and Shanghai, China. Some of these

markets, such as Liverpool, Barcelona, and Osaka, were import markets as well as mill markets. In addition, Le Havre, France, and Bremen, Germany, were important importing and distributing centers for United States cotton. Since World War II government agencies have controlled much of the importation and distribution of cotton in most of these countries, thus reducing the importance of these markets.

Spinners' markets carry out the important function of making readily available to mills the quantities and qualities of cotton needed by manufacturers. In general, cotton is offered to spinners in lots of 100 or more bales, even running in grade and staple length. The quality may be indicated by description in terms of government standards, by samples submitted or displayed, or by private type.

Among the personnel of United States spinners' markets are mill buyers and their representatives, cotton shippers, merchants, brokers, representatives of growers' cooperative associations, and possibly other dealers. Mills located in the cotton-growing states often buy directly from growers or from ginners and other local buyers. In some seasons mills in these states are reported to obtain about 25 per cent of their requirements of raw cotton in this manner, nearly twice this proportion from shippers and their brokers, and the remainder from cotton merchants and growers' cooperatives. Mills outside the cotton-growing states are reported to obtain the largest proportion of their raw cotton requirements from shippers and their brokers, the next largest proportions from cotton merchants and from growers' cooperative associations or their brokers, and none from growers or ginners.

The raw cotton needed by mills for the manufacture of cloth and yarns already sold at fixed prices is usually purchased at fixed prices, but most of that required is generally purchased on call. When purchases are made on call, the basic price is usually fixed at a specified number of points on or off the price of a designated futures contract, the buyer usually being given the option of deciding when the price shall be fixed. Prices of raw cotton are usually set when the prices of the manufactured products are fixed. By purchasing in this manner, mills obtain at least partial protection against losses from changes in price.

Cooperative Marketing.—Attempts of United States cotton farmers to improve their economic condition through cooperative marketing date back to the early 1870's. Thereafter many cotton associations were organized. Several covered the entire cotton-growing South; others were local in character and limited in influence. The early organizations encountered many difficulties, either because their objectives were unattainable or because their plans and operating procedures were poorly conceived and executed. Whether they were successful or unsuccessful, however, they all contributed something to the background of experience which led to the modern system of cooperative marketing of farmers' cotton.

The emphasis of cotton cooperative associations is laid primarily on marketing members' cotton in the most efficient way, obtaining for members the highest possible price based on quality, and rendering improved marketing services at a minimum cost. Such marketing services include classing, assembling, transportation, ware-

Table 1—STATE AND REGIONAL COOPERATIVE COTTON MARKETING ASSOCIATIONS, 1951

Association	Headquarters	Year of incorporation
Oklahoma Cotton Growers Association	Oklahoma City, Okla.	1921
Staple Cotton Cooperative Association	Greenwood, Miss.	1921
North Carolina Cotton Growers Cooperative Association	Raleigh, N. C.	1922
Southwestern Irrigated Cotton Growers Association	El Paso, Texas	1926
California Cotton Cooperative Association, Ltd.	Bakersfield, Calif.	1927
Mississippi Federated Cooperatives (A.A.L.)	Jackson, Miss.	1929
Mid-South Cotton Growers Association	Memphis, Tenn.	1930
South Texas Cotton Cooperative Association	Corpus Christi, Texas	1932
Cotton Producers Association	Atlanta, Ga.	1933
Texas Cotton Growers Association	Dallas, Texas	1935

housing, financing, insurance, hedging, selling, and shipping. Savings effected in performing these services are returned to growers in the form of patronage dividends based on the number of bales delivered. Associations also take an active part in programs for improving cotton quality and marketing conditions and facilities.

As of 1951, there were 10 large-scale state and regional cooperative marketing associations operating in the United States. Their names, addresses, and dates of incorporation are shown in Table 1. The total quantity of cotton handled by these and other large-scale cooperative cotton marketing associations in the years 1921-1922 to 1949-1950, together with the proportion which this cotton represented of total United States ginnings for each year, is given in Table 2.

Table 2—COTTON HANDLED BY LARGE-SCALE COOPERATIVE COTTON MARKETING ASSOCIATIONS, 1921-1922 TO 1949-1950

Marketing season	Number of associations operating	Cotton handled (in running bales) ¹	Per cent of total ginnings handled cooperatively ²
1921-1922	8	418,363	5.2
1922-1923	10	723,791	7.4
1923-1924	14	903,562	8.9
1924-1925	15	1,096,507	8.0
1925-1926	15	1,472,586	9.1
1926-1927	15	1,208,663	6.8
1927-1928	16	823,105	6.4
1928-1929	16	1,164,330	8.1

¹ Not including merchandise cotton purchased by the American Cotton Cooperative Association from 1930-1931 to 1942-1943.

² Total ginnings as reported by the U.S. Bureau of the Census.

In addition to large-scale state and regional associations, there are numerous local associations, and these generally comprise the membership of the state or regional associations. Most of the large associations are affiliated in turn with the American Cotton Cooperative Association, incorporated on Jan. 13, 1930, which super-

seded the American Cotton Growers' Exchange, organized in 1921 by the Texas, Oklahoma, and Arizona associations as a nonstock, unincorporated association.

When the American Cotton Cooperative Association was organized, its principal functions were the selling and financing of cotton received from member associations. Later it was decided that the national organization should perform other services incidental to the handling and merchandising of cotton. These included operation of interior classing services jointly with state and regional associations, and control of transportation, warehousing, insurance, hedging, accounting, billing, and invoicing. The functions of state and regional associations were confined largely to execution of general operating policies, membership contact work, bookkeeping incidental to members' accounts, and joint operation of interior classing and assembling. Subsequently, the functions of the American Cotton Cooperative Association were curtailed considerably, and more of them were performed by state and regional associations. Some of the associations are also affiliated with the Memphis Sales Service, a central agency which serves a number of local groups as well as these central associations.

Futures Markets.—A cotton futures market is a place where futures contracts are bought and sold. Such contracts provide for delivery or receipt of stated quantities of spot cotton during a specified future period at a fixed price for the basis grade and staple length. They are rigidly standardized with respect to the size of the contract unit; time, place, and manner of delivery; grades and staple lengths deliverable; margins required; classification, weighing, warehousing, and inspection of cotton; and other considerations. Transactions in futures contracts are used primarily for speculative and hedging purposes, and relatively little spot cotton is delivered against them. Transactions in spot markets, on the other hand, are made generally in connection with the actual merchandising of spot cotton. In the United States the unit of futures contracts is either 50,000 pounds, gross weight, of cotton in 100 square bales, or 25,000 pounds, gross weight, in 50 bales.

Before World War II exchanges for buying and selling futures contracts for United States cotton were located at New York, New Orleans, and Chicago in the United States; and at Liverpool, England; Le Havre, France; Bremen, Germany; and Osaka, Japan. Futures markets for other than United States cotton were located at Liverpool; Alexandria, Egypt; and Bombay, India. Most of these markets were closed during the war and have not reopened. As of 1951, the only active futures contract markets were New York, New Orleans, Alexandria, and Bombay. In the United States cotton futures ex-

changes are corporations operated on a nonprofit basis under regulations in accordance with the provisions of the Cotton Futures Act and the Commodity Exchange Act (1936).

Deliveries of cotton in settlement of futures contracts must be made from approved storage places at a designated delivery point or points during a specified month. Delivery on New York futures contracts may be made at New York, Norfolk, Charleston, Savannah, Mobile, New Orleans, Houston, and Galveston; on New Orleans futures contracts, at New Orleans, Houston, and Galveston. Government regulations of futures trading in the United States include specific provisions for additions to or deductions from the contract price for cotton of deliverable grades and staple lengths other than the basis quality—Middling 15/16 inch (before August 1939, Middling $\frac{7}{8}$ inch)—tendered in settlement of the contract. The particular designated point at which delivery is made, the day of the month on which the cotton is tendered, and the number and combination of tenderable grades and staple lengths to be delivered are at the seller's option, but due notice of intention to deliver generally must be given five business days prior to the date of delivery.

Trading personnel in cotton futures exchanges in the United States is confined to members, but a large proportion of the contracts executed are for nonmembers. Membership in the exchanges is generally limited. Thus the number of memberships in the New York Cotton Exchange is limited to 450, with a few members at times holding more than one membership. Members include representatives of most of the major domestic and export shipping firms handling United States cotton. Traders include speculators, who buy and sell mainly to profit from changes in price, and hedgers (principally cotton merchants and manufacturers), who buy and sell futures contracts as a means of transferring to speculators or to other hedgers at least some of the risks from changes in spot cotton prices.

Futures exchanges supply a continuous and ready market where changes in supply and demand are promptly reflected in price changes. Market news, assembled through the facilities of the exchanges and the Department of Agriculture, and price quotations of the exchanges, which are available to millions of persons in the United States and other countries, contribute materially to the marketing of spot cotton from the farmer to the manufacturer. The volume of trading in futures and the breadth of the market are usually such that a substantial volume of contracts may be bought or sold without greatly affecting the price level. This and futures trading in general tend to reduce seasonal changes in cotton prices and changes from one season to the next.

Prices of Spot Cotton and Futures Contracts.—*Spot Prices in Local Markets.*—The general level of cotton prices and the changes (both short- and long-time) in local markets in the United States are determined largely by the same forces of supply and demand that determine prices in the central markets and prices of future contracts. Consequently, there is a rather close correlation between the prices received by farmers in local markets and those quoted in central and futures markets. This is clearly indicated in Table 3, which gives annual average prices from 1920 to 1949. The relationship would doubtless be even closer if the prices shown were entirely

comparable. As it is, however, the estimated prices received by farmers presumably represent an average of all qualities of cotton, which may differ somewhat from year to year, whereas the prices in the central markets and the futures quotations represent a specific quality. Furthermore, the prices received by farmers, which represent weighted seasonal averages, are heavily weighted with the prices existing during the fall months, whereas the market prices are simple averages of the 12 months, August-July.

Largely as a result of differences in quality and of differences in the cost of moving cotton to consumption centers, cotton prices vary considerably from one local market to another. Studies made by the Department of Agriculture show that average prices paid to farmers in local markets tend to be relatively high in those markets where the average quality of the cotton sold is high and relatively low where the reverse is true. Moreover, average prices tend to be lower in markets where transportation costs to consumption centers are highest. One of the studies showed that in 1936-1937 growers in 5 selected local markets in Oklahoma, representing a surplus-producing area far removed from consumption centers, received prices averaging about 2.60 cents per pound lower than the average in 11 selected local markets in North Carolina, a consuming center for cotton. About 1.40 cents of the difference was estimated to be due to differences in grade and staple length of the cotton sold, and 1.20 cents to differences in transportation costs and other factors. With costs and prices much higher than in the mid-1930's, non-

quality differences in price were much greater in the early 1950's than as indicated in this study. In 1950-1951, Middling $1\frac{5}{16}$ -inch cotton in seven important markets in Texas and Oklahoma averaged 2.39 cents less than the same quality of cotton landed at mills.

In the Mississippi Delta, and in other localities where the average staple length of the cotton produced is longer than in other parts of the cotton belt, average prices paid to growers generally are substantially higher than in most other local markets. In many markets, however, it has been found that there is often comparatively little or no differentiation made in prices paid for individual bales of different quality. As a result, individual farmers may find it advantageous to sell poor-quality cotton in the market on the reputation of the community, but this practice, by lowering the average quality sold in the market, reduces the average price level in the market at the expense of those producing higher-quality cotton. As we have indicated, however, this situation has been improved.

Spot Prices in Central and Export Markets.—As in local markets, cotton prices in central markets differ somewhat from one market to another. Since prices quoted in the various United States central markets are for cotton of a particular grade and staple, however, these differences are due largely to differences in transportation costs to consumption centers and to a smaller extent to differences in terms and conditions of sale and in the character of the cotton sold. In addition to quotations on the basis grade and staple (Middling $1\frac{5}{16}$ inch), quotations for many other qualities of American upland cotton are available for some of the important central markets of the cotton belt. These quotations have been used for many years as a guide to value by merchants and others in making transactions, by bankers and others extending credit, and by insurance adjusters in settling claims. Since shortly after the passage of the Cotton Futures Act in 1916, official quotations for various qualities in central markets have been used in calculating prices for cotton of tenderable grades above and below Middling delivered in settlement of futures contract obligations.

The Cotton Futures Act, as amended directs the secretary of agriculture to require that differences between prices or values of Middling cotton and those of cotton of other grades in certain specified central markets be based solely upon the grades of the official cotton standards of the United States, and that they be the actual commercial differences established by the sale of spot cotton in such markets. To carry out these regulations, each market maintains a quotations committee whose organization and personnel are subject to the approval of the secretary of agriculture. The committee is directed to ascertain impartially and carefully, and to publish on each business day, the price or value of Middling $1\frac{5}{16}$ -inch cotton and the differences between its price or value and that of cotton of other grades and staple lengths represented by the official cotton standards of the United States. Quotations are made daily at the close of the futures market showing the price of Middling $1\frac{5}{16}$ inch and the premiums and discounts for the other grades.

Spot Prices in Mill Markets.—Because of differences in places of delivery and in terms and conditions of sale, cotton prices in mill markets

are usually higher than those prevailing for the same grade and staple length of cotton sold in central markets and in farmers' local markets. Cotton is usually offered for sale in spinners' markets in lots of 100 or more bales, even running in grade and staple length, whereas in central and local markets much of the cotton is sold in small lots, not even running in grade and staple length.

Prices of Futures Contracts.—For the most part, futures prices are determined by the same general supply and demand conditions which determine the prices of spot cotton. Short-time changes in supply and demand, however, are reflected somewhat more promptly in futures prices than in spot prices. In fact, futures prices are disseminated in spot markets and are used by buyers and sellers in arriving at prices for spot cotton. Over short periods, therefore, spot cotton prices tend to follow the lead of the prices for futures contracts. This should not, however, be interpreted to mean that the prices of spot cotton are determined by the prices of futures contracts. Prices of spot cotton and futures contracts are each influenced by the other, and both are determined largely by present and anticipated demand and supply conditions. While changes in prices of spot cotton are generally not much different from those for near-month futures contracts, they sometimes vary quite widely from their normally expected relationship. Prices for futures contracts for more distant delivery months at times vary considerably from those for near-active months and from prices for the basis quality of spot cotton at delivery points. With plenty of spot cotton immediately available in the market, the prices of futures contracts are normally expected to exceed prices of the basis quality of spot cotton at delivery points by amounts approximately equal to the cost of carrying spot cotton to the date of maturity of the futures contracts. Prices of New York futures contracts for delivery in different months, however, have varied irregularly and at times widely from the normally expected relationship. Considerable variation in the relationship between different futures markets also occurs from time to time. These variations, as well as those between delivery months, tend to be kept to a minimum by traders who buy in the market or contract month in which prices are considered relatively low, and simultaneously sell in the market or contract month in which prices are considered relatively high. When the relationships have been restored to a more nearly normal basis, the trader reverses his position, thereby profiting from the changes in the price relationships.

Price Relationships Between United States and Other Cottons.—*Relationships in a Given Market.*—For many decades Liverpool was not only one of the world's principal cotton markets, but also the only one in which prices were quoted frequently and regularly for cottons from all principal and some minor exporting countries. It provided prices for the several growths that were comparable with respect to time, place, and type of currency. In addition, it was sufficiently active so that most of its quotations were based on actual transactions. Consequently, until the end of March 1941, when the Liverpool market was closed for an indefinite period, its prices were often used in comparing the prices of different growths of cotton. A review of some of the price relationships which have existed in this and other

markets is important to a proper understanding of some of the major aspects of marketing cotton.

Average price relationships between various types of cotton for intermediate and longer periods are largely a reflection of the relative qualities and spinning utilities of the various growths. One of the leading quality factors affecting the comparative spinning utility of different cottons is staple length (together, possibly, with other elements of quality associated with staple length). The significance of this factor (and of any associated factors) in relation to comparative cotton prices is indicated in Table 4, which shows 20-

Table 4—AVERAGE PRICES AND PRICE RATIOS AT LIVERPOOL, 1920-1939

Type of cotton	Actual prices (in cents per pound)	Price as percentages of United States cotton	Approximate staple length (in inches)
Egyptian Sakellaridis, Fully Good Fair	28.97	168	1 3/8
Egyptian Uppers, Fully Good Fair	21.29	123	1 1/8
Peruvian Tanguis, Good	21.06	122	1 1/8

American, Middling "Fair Staple"	17.26	100	7/8-15/16
Indian Oomra, No. 1 Fine	13.48	78	3/4-13/16

year (1920-1939) average prices and price ratios at Liverpool for several different growths of cotton, together with the approximate average staple length of these cottons. Except for the disrupting factors of World War II and the early postwar period, the inclusion of later years would probably produce approximately the same relationships.

If price data were available for exactly the same cottons in other markets, a long-time average ratio of one to the other probably would not differ greatly from those which existed in Liverpool. Thus in Osaka, where prices of United States and Indian cottons are available for the years 1920-1938, the average price of the so-called Indian Acola group was equivalent to about 79 per cent of the average price of American Middling $\frac{7}{8}$ inch. The ratio of Indian cotton to United States cotton in the Liverpool market for the same years averaged 78 per cent. While it is not known exactly how the quality of the Acola group compared with that of Oomra during this period, these price ratios suggest that the two cottons were very similar in quality. In this connection, it is significant to note the relationship between the average New Orleans prices of Middling American upland cotton of staple lengths ranging from $1\frac{3}{16}$ to $1\frac{1}{4}$ inches for the 17-year period 1923-1939, as shown in Table 5.

For the most part, there is a fairly close and direct relationship between the length of staple, the count of the yarn produced therefrom, the fineness of the fabric into which it is woven, and the price of the resulting products. These factors, together with the relationship of staple length to the amount of spinning waste and to the cost of processing, account largely for the premiums paid for the longer staples.

Questions asked of the Department of Agriculture indicate that some persons with considerable knowledge of cotton prices do not understand how over a period of years important trends

have occurred in the relative quantities of some of the different growths produced and consumed without being associated with a trend in the price ratios. An explanation of this should contribute to a more thorough understanding of price relationships between growths as well as of those between different qualities of United States cotton. The trend in consumption without a trend in price ratios is due to the fact that, as the price of cotton of one growth increases or decreases in relation to the prices of other growths, consumption of the relatively cheap cotton tends to increase in relation to that of the more expensive cottons. On the other hand, such shifts in consumption cause a greater relative consumption of the cotton which was or had been relatively cheap. This in turn results in shifts in the comparative prices of these growths. By such price changes and the accompanying reactions of spinners in the form of shifts to the relatively cheaper cotton, changes in the relative amounts of the various growths consumed become adjusted to changes in the supply. Hence, over intermediate or longer periods, the relative quantities of the different cottons consumed depend on the amounts available. The average price differentials or relationships over such periods, however, depend largely on differences in the physical properties of the cottons, including length, strength, uniformity, and other elements which collectively determine the spinning utility. This is true not only of cottons of different growths, insofar as they differ in quality, but also of cottons of different quality (or spinning utility) in the United States crop or that of any other country.

Although average comparative prices of various growths or qualities over a period of years largely reflect relative spinning utilities of the cottons, relative prices for short periods may be affected by a number of factors. These include (1) changes or anticipated changes in relative quantities of these cottons available; (2) changes in relative local or world demand for the different growths; (3) changes in the rate of exchange between the currency of the importing country and that of other countries, particularly one or more cotton-exporting countries; (4) changes in the relative transportation cost between the importing country and one or more of the exporting countries; (5) export subsidies; and (6) import duties.

Relationships Between Markets.—Comparative price levels in the various cotton-exporting and importing countries are important in the marketing of United States cotton. A review of central market prices in seven leading export countries (see Table 6) shows that in four of these coun-

¹ Average of 10 months. ² Average of 9 months. ³ Average of 5 months. ⁴ Average of 8 months. ⁵ Average of 11 months. ⁶ Average of 6 months. ⁷ Not available. ⁸ Support prices. Compiled by the Bureau of Agricultural Economics, Department of Agriculture, from official or reliable trade sources and special reports received through the Office of Foreign Agricultural Relations.

first year for which reasonably satisfactory acreage estimates are available, to 1924 the total acreage outside the United States ranged between 29,300,000 acres and a little more than 41,000,000 acres. In 1926 the total acreage of 40,000,000 acres was 4,600,000 acres less than the record United States acreage of that year, but thereafter the acreage in the other cotton-producing countries increased in relation to that of the United States, and in 1932-1933 was approximately 6,700,000 acres greater than that of the United States. Acreage in these countries continued to increase, while that of the United States declined, and in 1937 attained a peak of almost 59,000,000 acres. As a result of World War II, the estimated total acreage outside the United States in 1945—almost 37,500,000 acres—was the smallest in 22 years. By 1951, however, the total had risen to over 53,000,000 acres.

India and Pakistan.—In India cotton acreage and production rose rather sharply from 1900 until the depression of the early 1930's. That depression, like others, brought about some recession, but the low points in acreage and production were materially above the low point of the depression of 1920-1921 and those of earlier years. Despite a substantial recovery in acreage after 1932, however, the area planted to cotton in India never recovered to within 1,000,000 acres of the peak attained in the late 1920's.

Indian cotton acreage rose from about 20,000,000 acres in 1904 and 1905 to slightly more than 26,700,000 acres in 1928, and then declined to 22,150,000 acres by 1932. After the recovery in cotton prices and the inauguration of the cotton adjustment program in the United States, Indian acreage rose to 25,500,000 acres, but during World War II declined again, and in 1945 totaled only 13,751,000 acres. It increased slightly thereafter, and in 1949-1950 the subcontinent had a total cotton acreage of 14,655,000 acres, of which 11,793,000 acres were included in the Republic of India and 2,862,000 acres in Pakistan.

In the late 1890's, Indian cotton production averaged about 2,000,000 bales annually. It increased rather sharply thereafter, and for the five years before World War I averaged about 3,500,000 bales annually. The expansion in acreage which accompanied the small United States crops and high prices of the mid-1920's resulted in a peak production of more than 5,000,000 bales annually for a brief period. From then until 1944 production ranged between 3,500,000 and 6,000,000 bales annually, but in the years 1947-1949 the combined annual production of India and Pakistan was only 2,800,000 to 3,400,000 bales.

Yields per acre averaged about 74 pounds in India in the decade before World War I. Since 1918 yields have averaged somewhat higher, and in the decade ending 1943-1944 the average was 94 pounds per acre. In the five years ending 1950-1951 the average was about 98 pounds per acre. The unusually low average yields of India are due largely to the fact that much of the cotton is grown on badly depleted soils which have been under cultivation for hundreds of years, as well as to unfavorable weather conditions existing in some parts of the cotton-producing areas, to heavy damage from insects and diseases, and to the use of unimproved seed and primitive methods of cultivation.

Egypt.—Following the completion in 1902 of the Aswân Dam on the Nile River, which increased the summer water supply and brought

large new areas under irrigation, Egyptian cotton acreage increased appreciably. After the dam had been heightened in 1912, acreage rose again and in 1914-1915 reached 1,800,000 acres, as compared with 1,300,000 acres in 1903-1904. In the years immediately preceding World War I, Egyptian cotton won wide and favorable recognition in world spinning centers, where its longer staple commanded a premium over most other cottons.

After the outbreak of World War I, there were several periods of wide fluctuation in acreage and production in Egypt. Early in the war, in fear of a food shortage, the Egyptian government issued a decree restricting cotton acreage; thus the 1915-1916 acreage and production were 32 and 26 per cent, respectively, below those of the preceding year. The restrictions were removed late in 1915, and in 1916-1917 acreage expanded 40 per cent over the previous crop year. New restrictions were partly responsible for a decline in the 1918-1919 acreage. In the inter-war period acreage was restricted from time to time by the government, primarily in an endeavor to maintain or increase the price or the premium of Egyptian cotton over cotton from other countries. Such restrictions contributed to reductions in acreage in 1921, 1927, 1928, and 1932. With the sharp decline in cotton prices accompanying the depression of the early 1930's, voluntary reduction and government restrictions reduced the acreage from the all-time high of 2,162,000 acres in 1930-1931 to 1,135,000 acres in 1932-1933, the lowest level in more than 35 years. With the subsequent advance in cotton prices and the restriction of production in the United States, the acreage restriction law was relaxed and Egyptian acreage increased sharply, rising above 2,050,000 acres by 1937. During World War II government restrictions and scarcity of fertilizers were largely responsible for acreages of less than 750,000 acres in 1942 and 1943. Before the war had ended, however, acreage began to increase again and by 1948-1949 totaled 1,496,000 acres. By 1951 it totaled 2,054,000 acres.

Yields per acre in Egypt declined from an average of more than 500 pounds in the period 1895-1896 to 1899-1900 to an average of less than 350 pounds during World War I and the immediate postwar years. Thereafter average yields rose, and after 1939-1940 again were around 500 pounds. The rather marked decline during the 20 or 25 years after 1895 may be attributed to such factors as (1) the marked acreage expansion, which probably brought somewhat less productive lands under cotton; (2) the rise, because of inadequate drainage, of the subsoil water level in Lower Egypt after the completion of the Aswân Dam; (3) the extension of canal irrigation to the basin lands, thus eliminating the annual fallow or rest period and making it possible to utilize the land 12 months a year; (4) the damage of the pink bollworm during the years after its appearance in 1913; and, possibly, (5) the changes in the proportion of the different varieties produced. The substantial increase in yields since about 1920 has been due in part to a shift from longer-staple, lower-yielding varieties to shorter-staple, higher-yielding varieties; crop rotations and improved cultural practices; and improvements in the drainage system.

Brazil.—Cotton is grown in two widely separated regions in Brazil: the southern states and the northeastern states. Soil and climatic conditions differ greatly in the two regions, and the

cotton grown is largely of distinctly different types and qualities. Southern Brazil produces cotton of the American upland type, while production in the northeastern states consists largely of Brazilian tree cotton.

The total Brazilian cotton area increased from about 780,000 acres in 1911–1912 to 6,740,000 acres in 1940–1941. A large part of this increase took place during the 1930's, for the peak acreage in the 1920's was well under 2,000,000 acres. In the early part of World War II total cotton acreage declined from peak levels, but through 1943–1944 remained at or above 5,000,000 acres. It then recovered to near the peak, but dropped again to 4,500,000 acres in 1947–1948, 4,100,000 acres in 1948–1949, and 4,700,000 acres in 1950–1951.

In 1921–1922, the first year for which separate estimates are available, the cotton acreage in southern Brazil totaled 334,000 acres, or only about one fourth of that for the country as a whole. By 1923–1924 it had risen to 464,000 acres, but declined sharply in the late 1920's, and in 1929–1930 totaled only 155,000 acres, or less than one tenth that of all Brazil. During the 1930's, however, the southern acreage increased very rapidly, and by 1940–1941 it was estimated to total 4,585,000 acres, or nearly 70 per cent of the entire Brazilian acreage. Incomplete estimates indicate that the percentage for the 1950–1951 season was also fairly close to 70.

In the northeastern states, where cotton has been the traditional crop for many years, total acreage has not fluctuated so widely as in the south. Short-term fluctuations in the northeast appear to be caused to a considerable degree by variations in rainfall, since much of the region suffers periodically from severe droughts. In general, cotton in this area is not subject to as much competition from alternative crops as that grown in the coffee-producing southern states and thus has not been as sensitive to price factors.

Brazilian cotton production, like acreage, increased greatly from the period just before World War I to the beginning of World War II. From 1902–1903 until 1918–1919, total production ranged from just under 300,000 bales to a little less than 500,000 bales, with the trend slightly upward. In the following decade, despite substantial acreage increases, there was little net increase in production, for yields per acre declined materially. In the 1930's, however, production increased substantially, and the 1940–1941 crop totaled a record 2,505,000 bales. Production declined to 1,844,000 bales and 2,172,000 bales in the two succeeding years, but in 1943–1944 rose above the level of 1940–1941 to 2,700,000 bales. From that year through 1950–1951, however, the crop ranged between 1,260,000 bales and 1,635,000 bales.

Production in the southern states increased from 81,000 bales in 1930–1931 to a crop estimated at 1,857,000 bales in 1940–1941. The latter figure was equivalent to 74 per cent of the total Brazilian crop. In 1950–1951 production in this part of Brazil amounted to 1,068,000 bales, or 69 per cent of the total crop.

In the period 1911–1931, the average annual yield per acre of cotton in Brazil declined quite materially. In the decade ending 1920–1921 yields averaged 227 pounds per acre, whereas in the five years ending 1932–1933 they averaged only about 142 pounds. At least part of this decline was due to a drought in northeastern Brazil

which began at the end of 1930 and lasted to the beginning of 1934, but other factors were also apparently important. Since the early 1930's yields have increased somewhat, the average for the three years 1940–1941 through 1942–1943 equalling 183 pounds per acre. For the three years ended 1950–1951 the yields were considerably lower than in the early 1940's.

Soviet Union.—In the last quarter of the 19th century, Russia developed a domestic source of raw cotton supply in newly won Turkestan (Central Asia) and, to a smaller extent, in Transcaucasia. The introduction of American upland types, which largely replaced the indigenous varieties, and the construction of railroads connecting the cotton regions with European Russia contributed greatly to the expansion in the period. A number of measures intended to encourage cotton cultivation, such as the imposition and gradual stiffening of customs duties on raw cotton, some agronomic assistance, and tax privileges for cotton growers, were adopted in the years before World War I. The difficulty of shipping United States cotton to Russia during the war temporarily stimulated the further expansion of Russian cotton acreage, and in 1915 the total cotton area exceeded 2,000,000 acres. Of this acreage, Central Asia accounted for 88 per cent and Transcaucasia for the remaining 12 per cent. The production of lint, which reached its prerevolutionary peak in that year, was estimated at 1,532,000 bales of 478 pounds.

Acreage and production declined sharply with the general economic dislocation which the revolution of 1917 and the ensuing civil war brought in their train. The shrinkage of the market for cotton and the shortage of breadstuffs due to the disruption of communications with central Russia led to increased self-sufficiency in the cotton regions and a shift from cotton to cereals. By 1922 the area in cotton had dropped to an estimated 170,000 acres, and production to 55,000 bales. Thereafter, with the general economic recovery during the period of the New Economic Policy (NEP), Russian cotton acreage showed a marked upward trend. By 1928 it exceeded the prerevolutionary peak and totaled 2,400,000 acres. Expansion continued, and in 1931 the area in cotton exceeded 5,000,000 acres—a figure which was almost equalled or exceeded in each succeeding year until the Soviet Union became involved in World War II. By 1930 production had recovered to the 1915 level despite much lower yields per acre. From 1931, when production totaled about 1,845,000 bales, to 1939, when production reached an all-time peak of 4,000,000 bales, the upward trend was due entirely to increased yields. Indications are that from 1940 through 1949 the Russian crop ranged between 1,500,000 and 3,000,000 bales.

Yields per acre, which declined during the years of war and revolution, showed a marked upward trend from 1921, when they averaged less than 100 pounds, to 1927, when the average was only 12 pounds below the 1909–1913 average of 276 pounds. With the expansion of cotton acreage after 1927, most of which was on non-irrigated land, yields declined to 162 pounds by 1932, but then turned sharply upward to reach an estimated 368 pounds in 1939–1940. This increase appears to have been due largely to an extensive plan for growing only the variety best suited to each area and for handling the seed stock in the best way each year, to the use of greater quanti-

period 1927–1928 to 1931–1932 into three groups according to approximate staple length. Because there were differences in descriptions and in methods of determining staple length, however, and since the reports from many of the countries were incomplete, it is not certain to what extent the figures for staple length were comparable with those for the United States, which were based on official government standards and were determined by classing an adequate sample from each year's crop. On the basis of the distribution established by the bureau, however, it was found that during this five-year period about 48 per cent of the production in countries outside the United States was less than 7/8 inch in staple, 34 per cent from 7/8 inch to 1 3/32 inches, and about 17 per cent 1 1/8 inches or longer. The estimated distribution for the United States during this period was approximately as follows: 13 per cent less than 7/8 inch in staple; 82 per cent from 7/8 inch to 1 3/32 inches; 5 per cent 1 1/8 inches or longer. Of the cotton less than 7/8 inch in staple produced in the countries outside the United States, India and China together accounted for about 95 per cent. With the Soviet Union, they also produced a very large proportion of the total production of the cotton from 7/8 inch to 1 3/32 inches in staple. The Egyptian crop, almost all of which was 1 1/8 inches or longer in staple, and that of northern Brazil constituted a large proportion of the long-staple cotton production. In addition, Peru, the Anglo-Egyptian Sudan, and Uganda produced sizable amounts of long-staple cotton.

Because of the scarcity of data, it is difficult to determine how the exact proportions of the different staple lengths produced from 1927–1928 to 1931–1932 compare with earlier years. It is known, however, that since that period the proportions of both short-staple and long-staple cottons have decreased, while the lengths most nearly comparable with the bulk of the United States crop have increased, and that this trend seems to be continuing.

India.—If the data released by the Indian Central Cotton Committee are comparable from year to year, there has been considerable improvement in the quality of the Indian crop with regard to length of staple since 1915. The committee's reports indicate that for the years 1915–1916 to 1917–1918 the quantity of cotton produced in India with a staple length mainly 7/8 inch and longer constituted slightly less than 23.6 per cent of the total. In the early 1930's, however, the proportion in these lengths averaged more than 28 per cent of the total crop, and it was still higher in subsequent years. Thus a larger proportion of the Indian crop has become more directly competitive with the bulk of the United States crop. It should be noted, however, that, according to the Indian Central Cotton Committee, the quantity of Indian cotton with a staple 7/8 inch and longer available for consumption is reduced by poor ginning and by mixing longer with shorter staples. In 1948 the committee reclassified the varieties according to staple length, placing some varieties in a lower classification, and so reduced the comparability of later estimates with those of earlier years. It is generally agreed, however, that further increases in the production of the longer staples took place in the late 1930's and the 1940's.

China.—Little information is available on the quantity of the various staple lengths of cotton

produced in China, but before the Japanese invasion in 1937 there was a significant shift from native varieties, which in the main produce short-staple cotton, to American upland varieties.

Egypt.—The proportion of the cotton acreage in Egypt producing varieties with a staple length around 1 1/8 inches, which are similar in staple length to about 5 per cent of the longer American upland cotton produced in the United States, increased materially in the 1920's and 1930's. This increase was at the expense of Sakellaridis cotton, which averages about 1 3/8 inches in staple. From about 1921 to 1923 the acreage in varieties with an extralong staple was approximately 75 per cent of the total, the remainder producing varieties with staples mainly about 1 1/8 inches long. By the early 1930's the proportion of varieties with an extralong staple had declined to less than 45 per cent of the total. This trend continued in the 1940's and the early 1950's. As a result, a larger proportion of the Egyptian crop became more directly competitive with United States cotton.

Brazil.—In Brazil the trend in the quality of cotton produced has been somewhat similar to that which occurred in Egypt. Before World War II all but about 15 to 20 per cent of the Brazilian crop was produced in the northeastern states, where a large proportion of the crop was and still is tree cotton, which is about 1 1/8 inches and longer in staple. In 1942–1943, however, more than 80 per cent of the Brazilian crop was produced in the southern states, where most of the cotton is derived from American upland varieties which produce a staple length more nearly comparable with that of the bulk of the United States crop. In the late 1940's and early 1950's the proportion of the total Brazilian crop produced in the south declined to about 70 per cent. The ginning of this cotton, formerly not very satisfactory, has improved, partly as the result of legislation.

CARRY-OVER OF COTTON

As used with respect to cotton, the term "carry-over" refers to the quantity of ginned cotton on hand as of the beginning (or the end) of the cotton-marketing season. For many years the cotton-marketing season for the United States, as well as for some other countries, has been the 12 months from August 1 to July 31. The beginning-of-season carry-over of United States cotton represents the stocks on hand as of August 1, the date on which stocks of this cotton are usually at approximately their low point for the year and before ginnings from the new crop become appreciable. Stocks of cotton in many other countries do not reach a low point as of August 1, and ginnings from a given crop often become appreciable at considerably later dates. To obtain maximum comparability, however, the most generally used carry-over estimates of cotton produced outside the United States are also made as of August 1. One of the principal uses of carry-over statistics is in combination with production data to indicate the total supply of cotton available from season to season. When so used, the production estimates should be, and generally are, adjusted to represent within-season ginnings, so that any cotton from a given crop which has been ginned before August 1 and is included in the carry-over may be excluded.

United States Cotton.—During the period 1920–1945 the world carry-over of United States

cotton ranged from a low point of 2,700,000 bales in 1924 to an all-time high of 14,137,000 bales in 1939. In the same period the proportion of the world carry-over of United States cotton in stock in the United States ranged from 45 per cent in 1925 to 95 per cent in 1944. After 1939 the world carry-over of United States cotton gradually declined, and on Aug. 1, 1948 it was estimated at 4,600,000 bales. In 1949 and 1950 the carry-over increased somewhat, but in 1951 it decreased to about the 1948 level or lower. This decline occurred largely as a result of the marked increase in cotton consumption and the reduction in cotton acreage in the United States.

During World War II, with the halting of exports to important European and Asian markets and the resulting depletion of stocks in these areas, the carry-over of United States cotton outside the United States declined sharply and on Aug. 1, 1944, was estimated at only about 600,000 bales, the lowest level since World War I and only half that of 1939. Since 1944 the carry-over of United States cotton in other countries has been from two and one-half to five and one-half times as large as in that year.

Since 1930 varying proportions of the United States carry-over of United States cotton have represented stocks owned by the government or on which the government has advanced loans. The August 1 government stocks in both categories have ranged from a low point of 41,000 bales in 1948 to a high point of over 11,000,000 bales in 1939. The remaining stocks on hand in

the United States as of August 1—often referred to as free stocks because of their availability for use by mills or by cotton merchants, whereas much of the cotton owned or under loan by the government has not been accessible to the cotton trade at existing prices—include stocks held by mills and merchants and small quantities in the hands of farmers.

Cotton Produced in Other Countries.—The world carry-over of cotton produced outside the United States showed a marked upward trend from 1920, the first year for which comparable estimates are available, to 1945. The carry-over of this cotton as of Aug. 1, 1920, totaled 5,400,000 bales, as compared with 7,460,000 bales on Aug. 1, 1939, and 15,600,000 bales on Aug. 1, 1945. The increase in the carry-over of cotton produced outside the United States between World Wars I and II was approximately in line with the increase in the production and consumption of this cotton during these years. The sharp increase during World War II, however, resulted largely

from the reduced imports and consumption of cotton in the Axis-controlled areas of Europe and the Far East, which more than offset increased consumption in a number of other countries. From 1945 to 1949 increased consumption reduced the carry-over of cotton produced outside the United States to the 1939 level, and it remained at about this level in 1951.

During the entire period for which estimates are available, only about 70,000 to 180,000 bales of this cotton have been carried over in the United States. Most of the United States carry-over represents cotton held in manufacturers' warehouses for use in the production of goods for which cotton grown outside the United States, because of certain quality characteristics, is better adapted than cotton available from the United States crop.

All Cotton.—The world carry-over of all cotton on Aug. 1, 1945, was estimated at about 28,750,000 bales, the largest on record and larger than the average annual mill consumption during the 1930's. This figure represented an increase of 12,000,000 bales over the 1934-1938 average and was about four and one-third times as large as the world carry-over on Aug. 1, 1923 (the small-

est for any year since 1920). As a result of three very small United States crops and a sharp recovery in world consumption, however, the carry-over was reduced by 1951 to about 11,000,000 bales, the smallest in 20 years.

INTERNATIONAL TRADE IN RAW COTTON

Although world mill consumption increased in the period between World Wars I and II, international trade in cotton failed to follow this trend. This was particularly true during the 1930's, when the volume of cotton entering international trade channels contracted considerably. In each of the seven years 1932-1938, world mill consumption exceeded the average for the decade 1923-1932, whereas in only two of these years did world cotton exports exceed 1923-1932 average exports and then only by narrow margins. As shown in Table 2, exports in 1938-1939, the last full season before World War II, fell to 11,663,000 bales, the lowest with one exception (1934) since 1923, when the United States crop was unusually small. World consumption in 1938-1939, on the other hand, totaled 28,507,000 bales, the second largest on record and about 5,300,000 bales larger than the average for the decade 1921-1930.

Import statistics (see Table 3), which are somewhat more comprehensive than export fig-

83c COTTON — PRODUCTION, SUPPLIES, AND INTERNATIONAL TRADE (5)

ures, confirm the contraction in international trade shown by export data. Net imports of cotton by all countries for which statistics are readily available totaled 11,364,000 bales in 1938. This was 1,837,000 bales (14 per cent) less than the average for the decade ending 1930.

In addition to the decline in the total volume of cotton entering international trade channels, there was a radical shift in the composition of this trade during the interwar period. Of the average annual world exports of 12,748,000 bales during 1921-1930, the United States supplied 7,268,000 bales or 57 per cent, while India and Egypt furnished a large proportion of the remainder. In 1938-1939, United States exports fell to the lowest level in more than 50 years, totaling

only 3,327,000 bales, and represented only 29 per cent of the relatively small volume of cotton entering international trade channels that year. Exports of non-United States growths totaled 8,336,000 bales, the highest figure on record and 2,856,000 bales more than the average for the decade ending 1930. Since the combined exports from India and Egypt were only slightly larger in 1938 than in 1921-1930, most of this increase occurred in the exports of other countries. A considerable part was accounted for by the 1,500,000-bale increase in shipments from Brazil.

A large part of the reduction in cotton exports and imports during the latter part of the interwar period was due to reduced imports by Germany, France, Italy, the Soviet Union, and

China. In 1938 there was also a rather marked drop in imports by the United Kingdom, while Chinese imports, due to unusual circumstances, rose above the 1921-1930 level.

During World War II international trade in cotton was extremely small. A large percentage of the world's spindles, most of which had previously operated on imported cotton, were under Axis control. In addition, shipping facilities were scarce, and textile production in the United Kingdom was reduced, partly because of inadequate supplies of labor. An indication of the extent to which the war reduced international trade in raw cotton and of the extent of the subsequent recovery through 1949-1950 is shown in Table 4, which compares gross exports (net exports not being readily available) for the principal exporting countries of the world.

6. MANUFACTURING AND TEXTILE DISTRIBUTION. In this section are discussed (1) the world-wide distribution of cotton spindles and looms; (2) mill consumption of cotton in the United States and other countries; (3) cotton textiles in the United States; and (4) international trade in cotton textiles.

DISTRIBUTION OF SPINDLES AND LOOMS

A very large part of all the cotton consumed in the world is used by spinning mills. In these mills the cotton is converted into yarn through a series of operations described in the article on **TEXTILE MACHINERY**. Most of this yarn is used for knitting or weaving, although relatively small quantities are used as thread, twine, or cordage. Since so much of the cotton consumed is first spun and then woven into fabric, the largest cotton-consuming countries are generally those possessing the greatest numbers of spindles and

looms. Because of the wide variation in hours of machinery operation and in the quantity of cotton required per hour of operation when producing fine or coarse yarns, however, a given country's percentage of world mill consumption of raw cotton may from time to time differ materially from the percentage of the world's spindles located in that country. The type of spindles and their efficiency also greatly influence the amount of cotton used per hour of operation. For similar reasons, as well as because of variations in the proportions of cotton yarn used in mixtures with yarns of other fibers and in the proportions of cotton yarn used for knitting, the number of looms located within various countries may not give a very good indication of the relative quantity of cotton used in the production of woven fabrics within these countries. Nevertheless, it is desirable to have estimates of the number of spindles and looms of the various countries. In some instances, for example, estimates of cotton spindles and looms are available for countries for which there are no estimates of the exact quantity of cotton consumed.

Source: *Shinner's Cotton Trade Directory of the World, 1944*, p. 61 (New York 1944); International Federation of Master Cotton Spinners and Manufacturers Association, report of June 1950.

As shown in Table 1, in 1940 (except as otherwise noted) and 1950 the nine countries possessing the largest numbers of cotton spindles were Great Britain, the United States, Germany,

Japan, India, the Soviet Union, France, China, and Italy. Except for China, these countries also possessed the largest numbers of looms, at least as of 1940. In China the number of looms reported was less than half as large as in Italy, whereas the number of spindles was slightly greater than in Italy. Altogether, there were more than 40 countries for which estimates of the number of spindles and looms on hand in 1940 or in the late 1930's were available. Estimates of the number of spindles on hand in or near 1950 are available for most of these and many other countries, but comparable data on the number of looms are available for far fewer countries. According to these estimates, the number of spindles increased in more than half the countries listed in Table 1 and declined in most of the others. A very large percentage of the countries showing increases were cotton-growing countries.

COTTON MILL CONSUMPTION

During the period 1914-1939, there was a substantial upward trend in the total world mill consumption¹ of cotton, as well as a slight upward trend in per capita mill consumption. For the years 1934-1938 world consumption averaged almost 28,000,000 bales annually. A peak was reached during the crop year 1936-1937, when world mill consumption of all cottons totaled 30,638,000 bales, a record which stood until 1950-1951. During World War II, with limited consumption in the important Axis and Axis-controlled importing countries, world cotton consumption was much lower than in the years immediately prior to 1939. Even with record high consumption in the United States, India, Brazil, and a few other countries, world consumption from 1942-1943 through 1945-1946 averaged about the same as in the depression years of 1930-1932. World consumption recovered fairly rapidly after the war and in 1950-1951 reached a new record of approximately 31,700,000 bales.

For many years United States cotton represented substantially more than half the cotton consumed by all the mills in the world. In the 1920's, despite the fact that during the early part of the decade the United States crop was materially restricted because of heavy boll weevil damage, nearly 60 per cent of the total consumption by all mills consisted of United States cotton. In the 1930's, although average world mill consumption was approximately 3,600,000 bales greater than in the preceding decade, average annual consumption of United States cotton declined nearly 1,000,000 bales and represented less than half the total. Most of the change in average annual consumption during the two decades occurred outside the United States, for consumption of all cotton and of United States cotton in the United States averaged almost the same during each of these decades. In the 1940's and in 1950-1951, world consumption of United States cotton averaged about half that of all cotton,

largely because of the high level of consumption in the United States.

Mill Consumption in the United States.—For the years 1934-1938 mill consumption of cotton in the United States averaged just under 6,500,000 bales annually, or somewhat more than the average for the years immediately before and after World War I. In view of the increase in population, however, per capita consumption of cotton showed little upward trend (except for the war period) and possibly a slight downward trend since immediately before World War I. Peak consumption before World War II was attained in the 1936-1937 crop year, when United States mills consumed 7,950,000 bales of raw cotton, 98 per cent of which was cotton produced in the United States. During the war mill consumption rose very sharply, reaching an all-time high of 11,170,000 bales in the 1941-1942 season. In the six succeeding seasons it ranged between this figure and 9,163,000 bales, and then in 1948-1949 declined to 7,795,000 bales. Mill consumption rose somewhat in 1949-1950 to 8,851,000 bales and then, following the outbreak of the Korean war, jumped to approximately 10,500,000 bales in 1950-1951, but declined about 1,000,000 bales in 1951-1952.

United States mills use relatively little cotton produced in other countries. Since 1920 consumption of cotton grown outside the United States has represented only 2 to 6 per cent of total United States consumption. This imported cotton consists of fibers which either possess certain characteristics not found in United States cotton or are not produced in sufficient quantities in the United States to meet mill requirements.

Before the Civil War a very large proportion of the United States cotton mills were located in New England. Since then there has been a steady increase in the proportion of the mills located in the cotton-growing states, particularly in North Carolina, South Carolina, Georgia, and Alabama. Immediately before World War I the mills in the cotton-growing states accounted for about half of the total United States consumption, but by 1939 the proportion of cotton consumed by these mills had increased to 85 per cent and during World War II it averaged even higher. Because of the production of coarser goods in the cotton-growing states and of the greater number of hours for which spindles are operated per week, the quantity of cotton consumed in the cotton-growing states represents a larger proportion of the total United States mill consumption than is indicated by the proportion of spindles located in these states. In January 1914, mills in the cotton-growing states accounted for 40 per cent of all active spindles, and in 1939 for 74 per cent. The trend toward these states continued during and after World War II.

Mill Consumption in Other Countries.—Total mill consumption of cotton outside the United States showed a substantial upward trend from just before World War I until the outbreak of World War II. Peak consumption was reached in 1936-1937, when 22,688,000 bales were manufactured. This was about 6,300,000 bales more than the average annual consumption during the 1920's and represented a somewhat greater increase over the annual consumption immediately before World War I. During World War II, largely because of the limited quantities of raw cotton available to mills in the Axis-controlled areas, mill consumption outside the United States

¹ In the United States and in most other cotton-consuming countries, there is ordinarily no cotton consumed except that which is spun into yarn or otherwise used in other mills, such as mattress-manufacturing establishments. In most countries, therefore, mill consumption and total consumption are synonymous. In China, India, and a few other countries, however, substantial quantities of cotton are used for home spinning and weaving on hand looms and by individuals for padding garments. The great bulk of this cotton does not enter commercial channels and so is not included in estimates of the commercial crop of these countries or, in turn, in estimates of total commercial production or consumption.

declined to less than 13,000,000 bales. Consumption rose in the late war years and in the postwar period, and by 1950–1951 it had reached 21,200,000 bales.

Despite the rather marked increase in the total mill consumption of cotton in other countries between 1920 and 1939, exports and consumption outside the United States of United States cotton showed a significant downward trend. During the years 1920–1929, these countries consumed an average of slightly more than 7,250,000 bales of United States cotton annually. The average for the following decade declined by approximately 1,000,000 bales, and the average for the last five years before World War II was nearly 2,000,000 bales lower than that for 1920–1929. As a result of the war, exports and consumption outside the United States of United States cotton from 1941 to 1944 totaled only 1,000,000 to 1,500,000 bales annually. From 1945 to 1950 consumption rose from about 2,000,000 bales to about 5,500,000 bales.

The opposite trends in the use of cotton grown in the United States and that produced in other countries by mills outside the United States from 1914 to 1939 resulted in a very sharp downward trend in the proportion of total consumption outside the United States represented by United States cotton. In 1914, United States cotton comprised 50 per cent of all cotton consumed by other countries, as compared with an average of 44 per cent in 1920–1929, 31 per cent in 1930–1939, and only 25 per cent in 1934–1938. A considerable part of this decline was caused by the increased consumption of cotton in cotton-producing countries, including India, Brazil, the Soviet Union, China, and a number of countries producing and consuming smaller quantities. The expansion of consumption in these countries did not only reduce imports of United States cotton into some of these countries, such as the Soviet Union and India. It also tended to reduce cotton imports into the United Kingdom and other European countries which had formerly exported substantial quantities of cotton goods to India and some of the other cotton-producing countries, but no longer did so as the latter became more

nearly self-sufficient or even became exporters of cotton goods. In the 1940's, United States cotton averaged about 16 per cent of the total consumption in other countries and in some of the war years accounted for only 10 per cent.

A comparison of the raw cotton consumed by the principal consuming and manufacturing countries in the period 1934–1938 and the crop year 1949–1950 is shown in Table 2. In general, these countries are those possessing the greatest numbers of spindles and looms. Their importance as cotton-manufacturing countries, however, may differ considerably from their ranking in numbers of spindles and looms, as shown in Table 1.

COTTON TEXTILES IN THE UNITED STATES

Production.—The United States cotton textile industry is generally considered to include only those mills spinning, weaving, braiding, and finishing cotton yarns and fabrics and to exclude the knitting industry, which uses substantial quantities of cotton yarns produced by the cotton textile industry. According to the function performed, almost all the mills of the cotton textile industry fall into one of the following classes: (1) spinning, including twisting and winding; (2) spinning and broad fabric weaving; (3) broad fabric weaving; (4) narrow fabric weaving and braiding; (5) spinning, weaving, and finishing; and (6) finishing.

Spinning mills perform all operations incident to the preparation and processing of raw fiber and yarn. The yarns which they produce are sold to knitters and small weaving mills and to establishments producing thread, insulating wire, twine, cordage, and mops. The spinning and broad fabric mills, which comprise the most important of the classifications, include mills spinning yarn and weaving it into various kinds of fabrics, both gray and colored, which are sold to converters, cutters, and industrial users. The broad fabric weaving mills for the most part comprise small weaving establishments which purchase their yarns and manufacture such items as damasks, draperies, tapestries, upholstery, towels, and specialty fabrics. The narrow fabric and braiding mills are usually fairly small establishments which find it more economical to purchase the wide variety of yarns needed for the tapes, webbing, laces, woven labels, and other products which they manufacture. The spinning, weaving, and finishing mills, second in importance in the industry, include almost all the largest establishments. They handle the complete process of manufacturing cotton from the yarn to the finished fabric. These mills may also finish fabrics woven by other mills, and in some instances may manufacture articles from the finished goods. Finishing mills comprise those establishments which have no spindles and looms, but which bleach, dye, and braid fabrics on commission for the account of converters or for their own account.

By far the largest part of the output of the cotton textile industry consists of broad woven goods. Excluding tire fabrics, production of these goods is classified into nine major fabric groups. The percentage which each group represented of the total yardage produced in 1950 is as follows:

Duck	2	Fine goods	12
Narrow sheeting and allied fabrics	20	Wide fabrics	7
Print cloth yarn fabrics	37	Towels and toweling	5
Napped fabrics	4	Specialties and other fabrics	4
Colored yarn goods and allied fabrics	9

the difference between the returns to the grower for raising cotton and the cost of these goods to the consumer. In the case of cotton goods employed for industrial uses, the price of raw cotton often represents a considerably larger proportion of the total cost of the goods than it does for apparel and household goods sold at retail. Nevertheless, raw cotton still represents a comparatively small proportion of the total consumer's dollar spent directly or indirectly for cotton products. Estimates made by the Bureau of Agricultural Economics indicate that the farmer's share of the retail value of annual purchases of 42 cotton articles was 14 per cent in 1950, as compared with 11.8 to 12.8 per cent in each of the nine preceding years. Even a marked decline in the cost of producing raw cotton and in raw cotton prices, therefore, has a more limited effect on the ultimate consumption of raw cotton than if price margins between raw cotton and the goods sold at retail were not so great.

PRICES & MARGINS FOR COTTON PRODUCTS

Market Outlets in Other Countries.—In the 1920's and 1930's marked increases in the production of synthetic fibers in other countries were an important factor in restricting export outlets for United States cotton. By 1941 the estimated total production of rayon outside the United States amounted to 2,213,000,000 pounds (equivalent to more than 5,200,000 bales of cotton). This was more than 530 per cent larger than the 1931 production and compared with a total production of only 33,000,000 pounds in 1921. A large part of the increase in rayon production in the late 1930's occurred in the Axis countries and was the result of the efforts of these countries to become less dependent on imported products. After the outbreak of World War II, synthetic fiber production was stimulated further in these countries because of their almost complete inaccessibility to cotton and wool. As the war progressed, however, output was restricted appreciably, and by 1945 rayon production outside the United States had declined to less than 28 per cent of the 1941 level. It rose again in the postwar period and by 1951 had reached 2,666,000,000 pounds, equivalent to 6,273,000 bales of cotton.

Of still greater importance in limiting export outlets for United States cotton and in depressing prices received by United States cotton growers in the 1930's was the increased competition from cotton grown in other countries. The expanded production of this cotton has been discussed in the section on *Production, Supplies, and In-*

WORLD PRODUCTION OF IMPORTANT FIBERS

OFFICE OF FOREIGN AGRICULTURE

International Trade. Despite an upward trend in the total consumption of cotton outside the United States, the increase in production was even greater, and the world carry-over of cotton grown outside the United States rose substantially. As a result, annual exports of United States cotton declined from a range of 6,760,000 to 8,708,000 running bales in the early 1930's to a 50-year low of 3,327,000 bales in 1938-1939, the last full season prior to World War II. During the war the production of cotton outside the United States was greatly reduced as a result of military operations and government action to increase food production. The reduction in cotton consumption through 1944-1945, was considerably greater than that of production, however, and as of Aug. 1, 1945, the world carry-over of cotton produced outside the United States was from two and one-half to three times as large as in the early 1930's. Production and consumption of cotton outside the United States rose again in the postwar period, and by 1950-1951 production had reached 16,400,000 bales, but the carry-over of this cotton had dropped to about one half that of 1945.

Closely related to the expanding production and consumption of cotton produced outside the United States and the restricted export outlets for United States cotton is the increased mill consumption of locally grown cotton in countries formerly importing large quantities of cotton textiles. The bulk of these cotton textiles were imported from European countries and Japan, which used considerable quantities of raw cotton imported from the United States. Since 1938 the consumption of cotton and the production of cotton textiles in such cotton-producing and cotton-exporting countries as India, Egypt, Brazil, Turkey, Argentina, and Peru have increased materially, and the first three of these countries were net exporters in 1949 and 1950 of textiles made largely, if not entirely, of locally grown cotton. This switch in cotton textile production and in the source of raw cotton tends to stimulate consumption as well as production of cotton grown

in other countries. In any event, it weakens the competitive position of United States cotton in relation to that produced elsewhere.

While import duties on raw cotton are relatively minor, high duties on goods imported into the United States and other international trade barriers have restricted exports of United States cotton. In the period following World War I an increasing proportion of the limited funds available to other countries for the procurement of United States products was devoted to the purchase of automobiles and other industrial products. After World War II the United States government financed a very large proportion of United States exports of cotton and most other important products.

RESEARCH, SERVICE, AND CONTROL PROGRAMS

Federal and State Programs.—For many years federal and state agencies have attempted in various ways to assist United States cotton producers, distributors, and consumers. Among the earlier of these efforts, which are still in operation, are the work of state experiment stations and extension services and of the United States Department of Agriculture in (1) the development of better varieties; (2) the development of improved methods of farm operation; (3) the development of better methods of controlling insects and diseases; and (4) efforts to induce farmers to use better varieties and operating practices. The federal government has also aided farmers in organizing marketing associations; has issued outlook reports on cotton and other commodities; has established rules and regulations for cotton futures markets, warehouses, and, to some extent, spot markets; has issued market information; has established cotton quality standards and provided government quality classification to hundreds of thousands of cotton producers; and has provided marketing credit and in other ways attempted to strengthen the position of the cotton farmer in marketing cotton and other products. In addition, federal and state agencies have conducted extensive researches, and the federal government has provided payments designed to develop new and extended uses for cotton and other products grown by cotton farmers and has allocated funds to make increased quantities of food and clothing available to low-income farmers and nonfarmers. Various forms of federal aid have also been extended to farmers to assist them in becoming farm owners and in securing long-term and other credit at reasonable rates.

In anticipation of uncertain world conditions after World War II, the 79th Congress passed the Research and Marketing Act of 1946 to accelerate agricultural research and marketing service work. In the fiscal years 1948 through 1951, \$9,000,000 to \$19,000,000 was provided under the act to supplement other funds used for these activities. The act authorized the Department of Agriculture to make contracts with private and other research agencies under certain conditions. As a result, the department for the first time contracted for a considerable amount of research in cotton.

Other major activities of the federal government are the programs involving commodity loans, agricultural adjustment, and soil conservation.

Commodity Loan Programs.—The first gov-

ernment loan on United States cotton designed primarily to support or control the market price was made under the Agricultural Marketing Act of 1929, when the Federal Farm Board made loans on cotton through cooperative organizations on the basis of 16 cents a pound. The board made loans through cooperatives on the 1930 and 1931 crops at 90 per cent of the current market price. Under the Agricultural Adjustment Act in each year beginning with 1933 (except 1936), the Commodity Credit Corporation, an agency within the Department of Agriculture, has made loans designed to support cotton prices and to assist producers to market their cotton in a more orderly manner. The corporation's loan rates on Middling $1\frac{1}{16}$ -inch cotton, gross weight, have ranged from 8.60 cents per pound in 1938 to 31.71 cents in 1951–1952. As provided by law, the basic loan rates have been made on the basis of a specified percentage of the parity price, which is that price which would give a pound or a bale of cotton the same purchasing power as it had in the 60 months from August 1909 to July 1914. The loans have been nonrecourse loans, and as such often not only have helped to support the market price, but also have provided farmers with a guarantee against price declines. Under the loan programs, the corporation had made loans on 36,900,000 bales of cotton through July 31, 1949, but producers had redeemed, or the corporation had acquired title to and had sold, all but 3,800,000 bales. From August 1949 through February 1952 loans were made on an additional 4,100,000 bales, with repayments having been made on all but 400,000 bales.

Agricultural Adjustment and Soil Conservation Programs.—These programs have had as their main objectives (1) the adjustment of United States cotton production and other crops more nearly in line with consumption in order to increase prices and returns to growers and (2) the conservation and improvement of the soil in order to obtain higher yields per acre and lower unit production costs. Through these programs and other developments, the total acreage planted to cotton in the United States was reduced from 40,248,000 acres in 1933 to 24,683,000 acres in 1939 and to 19,990,000 acres in 1944. It rose somewhat thereafter, however, and by 1951 totaled 28,544,000 acres. Along with the reduction in acreage, the improvements in varieties planted, and the use of better cultural practices, yields per acre rose quite sharply (see section on *Production, Supplies, and International Trade*).

Under the adjustment and soil conservation programs, the federal government has made various types of payments to cooperating cotton producers and others. Total payments directly or indirectly applicable to cotton ranged between \$68,000,000 and \$266,000,000 annually from 1933 to 1943. During this period, total gross returns to farmers from the disposition of their cotton, excluding government payments, ranged between \$606,000,000 and \$1,426,000,000. Including government payments applicable to cotton, total gross returns to farmers from cotton and cottonseed ranged between \$749,000,000 and \$1,506,000,000, with government payments representing 5 to 19 per cent of the total. Since 1943 no such payments have been made directly to cotton, but many cotton growers have participated in the conservation program and have received government payments for soil-building practices.

Nongovernmental Programs.—Many private

agencies and individuals have made important efforts to improve the cotton situation and conditions among Southern farmers. These groups are so extensive that no attempt will be made to enumerate them here. Their activities relate to almost every phase of cotton production, marketing, and processing, and to some extent to the merchandising and distribution of cotton textiles as well. Outstanding among the various groups is the National Cotton Council of America, an organization representing producers, ginner, warehousemen, merchants, crushers, and spinners. Since its organization in 1938, it has spent hundreds of thousands of dollars annually in research, in the collection and dissemination of information, and in promotional activities designed to make the production, distribution, and manufacture of cotton and cottonseed more efficient and to expand the consumption of cotton and cottonseed products.

Research Coordinator, Agricultural Research
Administration, United States Department of
Agriculture.

COTTON BELT, the name applied to the principal cotton-growing region of the United States, extending from southern Virginia to northern Florida and westward to eastern Texas. After the Civil War the cultivation of cotton spread to the high plains of Texas and later to California, Arizona, and New Mexico.

COTTON FAMINE, the name given to the destitution produced in the English cotton-manufacturing districts, especially in Lancashire, by the American Civil War. With the blockade of the Southern ports, the cotton supply failed and English millowners were forced to close their factories, reducing nearly 2,000,000 persons to great distress. A relief fund was established, and loans were granted to the guardians of the poor for relief works. With the receipt of increased supplies of cotton from India, Brazil, and other areas, conditions gradually improved, and by July 1865 they had returned to normal.

COTTON FIBER. See MINERAL WOOL.

COTTON GIN, a machine which separates the cotton fiber from the seed, patented on March 14, 1794, by its inventor, Eli Whitney (q.v.). The invention is attributable in part to Mrs. Nathanael Greene, widow of the Revolutionary general, on whose plantation near Savannah, Ga., Whitney was residing at the time. Interested by a number of ingenious household contrivances he had produced, Mrs. Greene introduced him to certain gentlemen who had discussed the desirability of finding some mechanical means of separating cotton from the seed. Removal of the seeds by hand was so difficult that it required a day for one person to clean a pound of cotton. Whitney went to work at once and produced his machine within 10 days. The gin devised by Whitney consisted of a revolving spiked roller which pulled cotton through iron grids, the latter holding back the seeds, while a revolving brush removed the fiber from the spikes on the roller. The first cotton gins, operated by hand, cleaned about 50 pounds of cotton a day. In 1796 circular saws were substituted for the spikes on the roller, but in all essentials the saw gins which have been used in the cotton industry ever since correspond to Whitney's invention.

COTTON GRASS, the name applied to any sedge of the genus *Eriophorum*. About 10 species are distributed in bogs and other moist places in the Northern Hemisphere. The fruit is clothed at the base with a cottonlike substance which has been employed in making paper.

COTTON GUM, a large tree (*Nyssa aquatica*) found from Florida to southern Virginia and westward to Texas, Missouri, and Illinois. It may reach a height of 100 feet and a circumference of 3 to 4 feet. The wood is soft, though hard to split, and light brown in color. The tree is also called tupelo or tupelo gum.

COTTON MULE, a small mule of the southern United States. See MULE.

COTTON SEED. See COTTONSEED AND COTTONSEED PRODUCTS.

COTTON STATE, a nickname for Alabama.

COTTON WHIGS. See WHIGS.

COTTON WOOL, a name for raw cotton. The term is used to denote cotton used in an open, or untwisted, or unspun form for particular purposes such as stuffing automobile seats, interlining clothes, and lining boxes. In its more refined state, after treating with disinfectants, it is extensively used for surgical dressings. It is also important in the manufacture of gun cotton. Generally cotton wool is made of linters, or the short fiber removed from cotton seeds, or from other short fibers removed in the process of carding and combing lint cotton in the process of manufacture.

COTTONIAN LIBRARY, a valuable collection of ancient manuscripts, books, and coins, begun by Sir Robert Bruce Cotton (q.v.) and augmented by his son and grandson. His grandson, Sir John Cotton, desirous of making the library

a public one, an act of Parliament was passed in 1700 for this purpose; in 1707 another act authorized the purchase of Cotton House and library on behalf of the queen and her successors; and in 1730 it was deposited in a house in Westminster. The next year a fire broke out there, wherein 114 volumes of manuscripts were burned, lost or entirely defaced, and 98 rendered imperfect. A great number of the injured volumes were effectively restored, so that the library consists of nearly 900 volumes. Nearly 200 are state papers of the greatest value covering the diplomatic relations of Europe from the reign of Edward III to James I. It was then removed to a new building in Westminster, and in 1757 finally removed to the British Museum. In addition to manuscripts, it contains many valuable coins and antiquities.

COTTONMOUTH. See MOCCASIN SNAKE.

COTTONSEED AND COTTONSEED PRODUCTS. More than 2,000 years ago the Hindus mastered the use of the cotton fiber, demonstrating its remarkable adaptability for spinning into fabrics. The Hindus and the Chinese also recognized the value of cottonseed and developed crude methods for expressing its oil. They used this oil for their lamps and for medicinal purposes; the remainder of the crushed seed they fed to their cattle. But it remained for machinists and chemists in the United States to demonstrate the full potentialities of cottonseed, that it would furnish valuable food for man, feed for animals, and hundreds of other products of a wide range of usage.

Early Experiments.—A Dr. Otto of Bethlehem, Pa., is credited with the discovery of the first cottonseed oil produced in America. Samples of oil which he had obtained from cottonseed and several other vegetable oilseeds were exhibited in 1768 before the American Philosophical Association, accompanied by the statement that a bushel and a half of cottonseed would yield nine pints of oil. In 1783 the London Society for the Encouragement of Arts, Manufactures and Commerce offered a prize to any planter of the British West Indies who would express a ton of oil from cottonseed and produce five hundredweights of cake suitable for cattle feed. There is no record that anyone qualified for this prize.

Numerous experimental attempts were made to utilize American cottonseed, but the records of these are obscure. In 1799 a patent for "a process of extracting oil from cottonseed" was granted to C. Whiting of Massachusetts. In 1814 a machine for hulling cottonseed was patented by John Lineback of Salem, N. C. Details of both patents were destroyed by fire and it is not known whether either process was used. As early as 1802 it is reported that Capt. Benjamin Waring of Columbia, S. C., operated an oil mill, where he crushed flaxseed, sesame seed, and some cottonseed. Another record refers to Waring's mill in 1826, but says nothing about cottonseed. This would indicate that the processing of cottonseed had not then developed into a commercial enterprise.

In 1829, Francis Follet of Petersburg, Va., obtained a patent on "a machine for hulling and husking cottonseed and separating the hulls from the kernels." Follet in partnership with Jabez Smith, also of Petersburg, erected in that city a

mill which operated for a time and created considerable interest. Seed were crushed between a pair of revolving stones. Hulls and kernels were separated by a current of air from a fan. Power was supplied by two horses. It was claimed that the mill could hull and clean 20-25 bushels of seed an hour, yielding about 55 per cent of kernels (by weight). A bushel of kernels, it was stated, would produce more than 2 gallons of oil and 35 pounds of cake.

Follet and Smith reported in 1833 that they had erected three mills and that others, employing their machines, were rapidly progressing. They sold their patent rights for most of the Southern states to A. Plummer and Company, who were instrumental in the establishment of mills at Raleigh, N. C., Natchez, Miss., Florence, Ga., and Mobile, Ala. The largest of these, at Natchez, was capable, it was stated, of producing 1,000-2,000 gallons of oil daily. It is doubtful, however, that so large a quantity ever was produced. In 1836 a New Orleans journal reported the arrival of the steamer *Lamplighter* from Arkansas with 20 barrels of cottonseed oil and 20 tons of cottonseed cake, which possibly were products of the Natchez mill. Few details are available regarding these early mills including "a Cotton Seed Oil Factory and Insurance Company" incorporated by the Louisiana legislature in 1835 to be established in New Orleans. The Natchez mill is reported to have operated for about 10 years, but it and all the others failed.

The principal obstacle to all these early attempts to utilize cottonseed was the hull of the seed which, in American Upland varieties, is tough and covered with short fibers or fuzz known as linters. Early equipment ground up the hulls with the result that they absorbed a significant quantity of the oil. A low yield of oil and cake or meal of poor quality made the processing operation uneconomical. In addition to mechanical difficulties the problem of transportation was formidable. Seed had to be brought to mills over roads which were little more than trails. Transportation facilities for the shipment of products from mills were meager and markets were practically nonexistent, since the public generally was unfamiliar with cottonseed products and their uses.

Despite these difficulties there were a few men in the South who were not discouraged by the failure of the early mills. Among them were Dr. Edward J. Coxe and William Wilber of New Orleans. These men kept the subject alive by repeated statements in the press and periodicals that 100 pounds of seed would produce 2 gallons (15 lbs.) of oil, 48 pounds of seed cake and 6 pounds of soap stock. They pointed out that planters were discarding the seed from a 3,000,000-bale crop, which could be made to yield them millions of dollars. In 1854, Wilber constructed a mill at New Orleans. He and Frederick Good made a number of improvements in mill machinery. They produced oil, refined it, made soap, and placed cake on the market. About the same time two other mills were built at New Orleans, two at Memphis, Tenn., and one each at St. Louis, New York City, and Providence, R. I. Significantly, each of these mills was located at a point where seed could be brought to them by water. Cottonseed, being light and bulky, have always depended upon economical transportation. In the 1940's the greater part of the cottonseed that was crushed moved less than

100 miles to the mills, although the average distance increased after World War II.

Commercial Expansion.—In 1857, William R. Fee of Cincinnati invented a huller, which employed the principle of the modern machine. All previous efforts along this line had involved machines which ground up the hulls, resulting in inefficient separation of hulls and kernels and a high loss of oil. Fee's machine cut the hulls, thus making possible efficient separation, higher yields of oil and a better quality of cake. Fee also developed a hydraulic press, the type now most widely used. Several other patents issued in 1869 were important. One was for a huller developed by F. A. Wells of Memphis; two for linter machines were issued to W. F. Pratt of Bridgewater, Mass., and to G. W. Grader of Memphis. As a result of these inventions the industry, for the first time, was supplied with reasonably efficient equipment for two of the essential processes in cottonseed crushing: delinting and hulling.

The Civil War naturally retarded expansion of the industry. Of the seven mills reported by the census of 1860, only three survived the conflict. The almost complete destruction of the South's capital delayed development immediately after the war. The number of mills rose to 26 in 1870 and to 45 in 1880, but the next decade saw a very rapid expansion to 119 mills in 1890.

When the early experimenters sought methods of producing oil from cottonseed, they envisioned the oil as an illuminant which someday would replace whale oil, then widely used for that purpose. During the siege of one southern city during the Civil War, a merchant advertised that his supply of candles was exhausted but that he had received a supply of lamps equipped to burn cottonseed oil. However, the discovery of petroleum, about the time that the cottonseed industry was starting, eliminated whatever possibilities may have existed in the field of illumination. Throughout the early years there had been repeated assertions that cottonseed oil would make an excellent food, comparable to olive oil, and it was in this direction that markets developed.

Public acceptance of cottonseed oil as a food in the United States was slow. During the decade 1870-1880, when the industry was establishing itself, most of the oil produced was exported. Interestingly enough, Italy was the principal export market, taking about 40 per cent of the exports until 1880. France also was an important buyer. There is little doubt that a large proportion of these exports to Mediterranean countries was mixed with olive oil and sold under that name. The trade journals of the period frequently commented to the effect that large quantities of cottonseed oil, which left the South under its true name, returned to the United States, especially to New York City, as olive oil. The situation led Italian olive growers to demand protection. After 1881, when Italy more than doubled its import duty on cottonseed oil, United States exports to Italy practically ceased.

This decline in exports became general as a result of important developments in the domestic market. Most of the domestically consumed cottonseed oil had gone into soap. The quantity usable in that way was limited and the men interested in its production were convinced that cottonseed oil possessed many of the qualities of a high-grade edible oil. They naturally wanted

to develop this market, which would bring greater returns than would sale of the oil for soap. During the 1870's there was introduced into the United States from France a new product: oleomargarine (or margarine, as it is now known). At first margarine was manufactured only from animal fats. Beginning about 1880, however, cottonseed oil was used in margarine, first in small amounts, but later in increasing quantities. Thus appeared a new domestic market for cottonseed oil.

In the early days the effect of margarine on cottonseed oil was more indirect than direct. It was the practice of the meat packers at that time to sell their lard to refiners, who hardened it by the addition of other fats, particularly tallow and stearin, and sold it under their own name. Two of the principal ingredients of margarine in those days were neutral lard and oleo oil. The latter is produced from the best grades of edible tallow and yields, as a byproduct, oleo stearin. The demand of the margarine manufacturers for neutral lard left the lard refiners with a somewhat inferior product. Likewise their demand for oleo oil sharply reduced the quantity of high-grade tallow, which the refiners used to harden lard. There was available, however, a large supply of hard oleo stearin. From this situation arose the practice of mixing lard, oleo stearin, and cottonseed oil. This practice aroused the antagonism of the hog producers and dairymen who sought to legislate the new competitive products out of existence. No doubt there was at the time just cause for complaint. The mixture of cottonseed oil and lard was sold as refined lard. Manufacturers apparently did not try to keep the matter a secret, for it was widely discussed in the trade journals. However, consumers were probably unaware that they were not buying pure lard. There is also little evidence of fraudulent intent on the part of margarine manufacturers, but, after the product had left their hands, it was no doubt frequently sold as butter. This situation was not peculiar to products made of cottonseed oil. The period was one of widespread adulteration of food and other commodities. The advocates of reform of this situation fell into two groups: those who wanted general legislation to protect the consumer and those who desired specific legislation dealing with individual commodities, from which they might obtain competitive advantages. Because of its political strength the dairy industry had considerable early success in their campaign against margarine. In several states the production and sale of the product was prohibited and a federal margarine law was passed in 1886. This statute imposed annual license taxes of \$600 on manufacturers, \$480 on wholesalers, and \$48 on retailers and a product tax of 2 cents per pound. In 1902 the tax was raised to 10 cents per pound on yellow margarine and reduced to 0.25 cent per pound on white margarine. Wholesalers and retailers of the latter product were taxed \$200 and \$6 respectively. The original federal margarine law preceded by 20 years the first federal Food and Drug Act. While there were no doubt good reasons for the regulatory provisions of the law, an examination of the congressional hearings and debates reveals that the suppression of competition was a strong motive behind the tax features.

Attempts were made to pass similar legislation affecting mixtures of lard with other fats

COTTONSEED AND COTTONSEED PRODUCTS

and oils, but they were not successful. The lard refiners were learning a lesson from the fate which had befallen the margarine industry, for, as early as 1888, the two largest firms in the business announced that in the future their products would be labeled "lard compound."

One phase of the drive against lard mixtures and margarine was the attempt to show that such products were impure and even dangerous to health. This effort reacted to the benefit of cottonseed oil, for it was subjected to innumerable critical tests. The verdict was uniformly favorable to cottonseed oil. The chemists testified not only that it was not harmful, but also that it was a pure and wholesome food. While the federal taxes imposed upon margarine in 1886 seriously retarded the growth of that industry as a market, cottonseed oil made marked progress in the field of cooking fats. The lard refiners' production of an acceptable shortening made from cottonseed oil, lard, and other fats led to the emergence of a wholly new industry, later to be known as the shortening industry. The term "refined lard" was gradually discarded and at least 20 trademarked brands of cooking fat were placed on the market during the 1880's. In the next decade 45 new brands were introduced. Most of these contained cottonseed oil.

Significant improvements were made in the technology of oils and fats from 1885 to 1915. The development, by David Wesson, of the caustic soda process of refining cottonseed oil was one of these improvements. Bleaching with fuller's earth and deodorization with steam under a vacuum greatly increased the value of the oil as a food. Finally the perfection of hydrogenation, by means of which a liquid oil may be transformed into a solid fat, made possible the production of a shortening composed entirely of cottonseed oil. The first such product was placed on the market in 1911 and was widely advertised as an all-vegetable product.

Growth and Maturity.—The expansion of the crude oil mill industry in the South kept pace with improvements in technology; in fact, it exerted a constant pressure upon the chemists and refiners to make such improvements. In 1874 the United States cotton crop was 3,836,000 bales. Seed crushed, however, was only 84,000 tons or 5 per cent of production. By 1900 the cotton crop had increased to 9,535,000 bales and the quantity of seed crushed had risen to 2,479,000 tons or 53 per cent of production. The number of mills, which had reached 119 in 1890, increased to 369 by 1900 and rose to a peak of 882 in 1914.

As early as 1897 there was formed the Inter-State Cotton Seed Crushers Association, with 143 members representing crude mills, refiners, dealers, brokers, and supply firms. In 1898 the association adopted a set of trading rules, which defined certain trade terms and established standards for cottonseed oil and meal. These rules and standards have been improved and expanded over half a century and still serve the industry. The association has maintained a continuous existence, although in 1929 its name was changed to the National Cottonseed Products Association. After 1914 the number of cottonseed crushing mills declined until in 1950 there were about 330 plants in operation. This decline resulted from the decrease in production of cotton in certain areas and from the manner in which the industry developed. As already noted, transportation facil-

ities were very poor when the industry began its growth. Since seed could not be brought readily to centrally located plants, a large number of plants were erected close to the seed. As transportation and marketing facilities improved, each mill was able to extend the area within which it could buy seed. The industry became intensely competitive; poorly located or designed mills and those under poor management went out of business. While the number of mills declined, the percentage of seed production that is crushed rose to nearly 90 per cent. The capacity of the industry is more than sufficient to handle any size of crop which may be produced.

Marketing.—Cottonseed are separated from the cotton fiber at the gin. In most instances, producers sell their seed to the ginner at the time the cotton is ginned. The ginner combines the small lots of seed purchased from producers and sells in multiple-ton lots to the crushing mills.

Movement of seed to the mills is highly seasonal. Over 80 per cent of the crop reaches the mills during the four months ending with December. To handle this rapid movement, most of the mills operate 24 hours a day during the fall and early winter months. Even so, it is necessary for the mills to provide extensive storage facilities to care for the crop.

Mills base the prices they pay for cottonseed upon the total value of the products obtainable from a ton of seed. From this total value a mill will subtract its costs. It will also subtract the amount of profit it hopes to earn in return for risking its capital. What remains is, in theory, the price the mill will offer per ton of seed. Actually, the mill must meet its competitors' prices, even at the expense of some or all of its profit, or it will be unable to buy seed.

Mill Processes.—Most cottonseed are delivered to the mills by truck, but a small quantity comes by rail. Seed are unloaded chiefly by power shovel or pneumatic unloaders. A few mills employ hydraulic truck dumpers. As seed are unloaded, a sample is taken by a licensed sampler and is sent to an official chemist, who analyzes it for moisture, foreign matter, oil and protein content, and free fatty acids in the oil. On the basis of this analysis the chemist determines the grade of the seed and the mill bases its price upon that grade. Upon unloading, seed are carried to the seed house by mechanical conveyor. The seed house is usually a large, rectangular, steel building, notable for the 45° angle of its roof. Some mills employ tanks, either steel or tile, for seed storage. Regardless of the type, facilities for storage of cottonseed are equipped with mechanical cooling systems, which draw outside air through the seed. Most mills seek to bring the temperature of stored cottonseed below 60°F. as rapidly as possible. Such cooling is essential to preserve the quality of seed to be stored for any significant period.

Cleaning.—The first operation in the processing of cottonseed is that of cleaning. Seed are run over revolving and shaker screens and through pneumatic equipment to remove the various types of foreign matter that are present. Magnets are also employed to remove any metal, such as nails, which may be mingled with the seed. After cleaning, seed go to the lint room, where the short fibers are removed. The lint room, in both appearance and operation, is not unlike a cotton gin. The seed are fed into delinting machines, where they fall into a set of

ribs. A series of circular saws on a horizontal revolving shaft projects through the ribs just far enough to catch in the short lint. The saw teeth carry the lint through the ribs, leaving the seed behind. At the back of the saw the lint is removed by a brush revolving with the saw, but at a higher speed. The lint is collected from the brush by a reel or by air suction, passed to a condenser, and baled. It is known in the trade as cotton linters. Seed may be run through the delinting machines once, in which case the linters are known as mill run; or they may be run through twice and the linters are classed as first cut and second cut. The latter practice is used by most modern mills.

Removal of Hull.—In cottonseed processing, the next step after delinting is the removal of the hulls. This is performed usually by a bar huller, consisting of a concave bank of horizontal stationary knives held close to a second series of horizontal knives carried on a rotating cylinder. Seed are fed between the two sets of knives, which cut the tough hulls. From the hullers seed move through beaters, shakers, and separators, which loosen and then separate the hulls from the kernels or meats. The latter are then ready for the extraction of the oil.

Extraction of Oil.—There are three processes for the removal of oil from cottonseed: the hydraulic press; the expeller press; solvent extraction. The oldest and most widely used is the hydraulic press. The meats are passed through a series of heavy steel rolls, which flatten them into flakes. In this form they are fed into steam-jacketed cookers equipped with stirring blades and moisture controls. Cooking time varies with the volume of meats handled. Generally it ranges from 80 to 120 minutes at temperatures of 200°-225°F. A shorter cooking period and higher temperatures are employed in certain types of pressure cookers.

As they leave the cooker, the meats are run through a former, which shapes them into slabs that will fit into the press boxes. These slabs then are wrapped in very strong wool or nylon cloth, known as press cloth, and are then ready for the press. The hydraulic press consists of a series of rectangular steel boxes, one above the other. The entire press rests upon a vertical, hollow, steel cylinder, inside of which operates a plunger or ram. Base and head of the press are connected by four steel posts. When the slabs of meats have been placed in the press boxes, hydraulic pressure is applied to the ram, which presses each box against the one above it and the top box against the head of the press.

Pressure is increased to about 2,000 pounds per square inch (on the cake surface). Oil is forced from the meats and through the press cloth. It flows between the press boxes and into a collecting pan at the bottom of the press. There it is piped to settling tanks, where fine particles of meal settle out. It then is pumped to storage tanks or directly into tank cars for shipment.

Cottonseed meats usually are kept under pressure for 20 to 40 minutes. When the available oil has been expressed, the slabs of cake are removed from the press and run through a cake stripper, which removes the press cloth. In some instances, the edges of the cake are trimmed and reworked for the oil which they contain. The cake is put through a cake breaker, which cracks the slabs into smaller pieces. These may be screened into various sizes, for sale as cracked

cake, or fed into an attrition mill, which grinds them into meal. Meal may be processed further by moisture, heat, and pressure into cubes or pellets. Cubes and pellets have the advantage of being easy to handle and uniform in texture and composition.

While most cottonseed are processed on the hydraulic press, a significant number of mills use the expeller or screw press. In this operation seed move through the same steps previously described, up through the rolls. From the rolls the flaked meats pass to a cooker or conditioner, which is part of the press. There they are brought to a proper temperature and moisture content. The expeller press resembles a large meat grinder, in that it has a screw or worm revolving inside a horizontal steel barrel. Meats flow from the conditioner into one end of the barrel, where pressure created by the revolving screw expels the oil, which then flows through small openings in the underside of the barrel. The cake, in flaked form, is extruded at the other end of the barrel. Very high pressures, up to 10-12 tons per square inch, are created in the press. The expeller is a continuous-process operation and can be worked with much less labor than the hydraulic press system. It, however, requires more power.

The third method of obtaining oil from cottonseed is solvent extraction, which has been used in Europe and in the American soybean industry for a number of years. The process has been most successful, when used on raw materials with a relatively low oil content. Cottonseed meats, containing about 35 per cent oil, have raised some difficult technical problems. These are being overcome, however, and a number of mills have installed solvent systems and others are making such installations.

In solvent extraction, cottonseed are put through the regular milling processes up to the point where they leave the rolls. The flaked meats then are exposed to one of several solvents, which dissolves the oil. Solvent and oil are separated by a series of evaporators and stills, while any solvent remaining in the meal is removed by light pressing and heating. Solvent extraction has the advantage of recovering 30-40 pounds more oil per ton of seed than hydraulic or expeller processing. When the price of oil is high, this is a significant advantage to the processing plant. Solvent extraction also requires considerably less labor than hydraulic processing, although operators must be men with intensive technical training. The sharp rise in wage rates, which occurred in the 1940's, has encouraged the installation of expeller and solvent operations.

Cottonseed Products.—The quantities of products, which the mills recover from a ton of cottonseed, are subject to considerable variation. A study of official grade reports shows that the seed crushed during a single season in Tennessee produced from 145 to 395 pounds of oil per ton. Meal yields on the same seed varied from 693 to 1,036 pounds per ton. Comparable variations occur in other states. Such variations may be attributed to the variety of the cotton planted, to cultural practices, and to climatic conditions prevailing during growing and harvesting seasons. While the variation in the quantity (and the quality) of products obtainable from individual lots of seed is quite wide, national average yields are reasonably stable, as shown in the following table, which records in pounds the aver-

age quantity of cottonseed products produced per ton of seed crushed, 1940-1949 crop years (beginning August 1):

Crop year	Oil	Cake or meal	Hulls	Linters
1940	324	888	504	171
1941	312	874	495	186
1942	311	887	482	190
1943	313	928	469	185
1944	311	919	463	182
1945	312	879	480	182
1946	315	882	471	191
1947	312	930	452	186
1948	320	897	463	183
1949	323	893	469	179

The extent to which mills can vary the quantity of products obtained per ton of seed is strictly limited. The yield of cake or meal may be increased somewhat by permitting more hulls to remain with the meats. This, of course, reduces the yield of hulls. It also reduces the protein content of the meal, which is the basis of its value. If an excessive amount of hulls is left in the meats, the yield of oil will be reduced through absorption. The yield of linters may also be varied moderately, both in total and as between first and second cuts. Some variation in linters output per ton of seed may be noted from one season to another in response to changes in the market price.

Oil.—Oil is the most valuable product of cottonseed, accounting (on the average) for about 55 per cent of the total value of all four products. About 90 per cent of all the cottonseed oil produced in the United States reaches the dinner table in one form or another. Before being used in food, crude cottonseed oil is refined. This involves treatment with a caustic soda solution, which combines with the free fatty acids in the oil and also absorbs foreign matter and some of the coloring. The mixture of caustic soda and other materials, known as foots or soapstock is separated out by gravity or (more commonly) by centrifuges, leaving what is known as refined oil. The soapstock is used in a number of inedible products, including soap, washing powder, paint, composition roofing.

The refined oil is put through a number of further processing steps, depending upon the type of finished product in which it is to be used. For the manufacture of shortening, margarine, and light-colored oils, cottonseed oil is bleached. If the oil is to be packaged as salad oil, it is winterized. This is a chilling process, which causes the stearin fraction of the oil to solidify. This is separated from the liquid fraction, leaving an oil that is clear even at low temperatures. Oil which is to be used in shortening or margarine must be changed from a liquid to a solid. This is accomplished by the process of hydrogenation, in which pure hydrogen gas is pumped into the oil at a temperature of 212°-215°F. The process may be controlled to produce oils of varying melting points and other characteristics. The last step in processing cottonseed oil, prior to the production of finished products, is deodorization. Both winterized oil, prepared for salad oil and cooking oil, and hydrogenated oil, prepared for shortening and margarine, have characteristic odors and flavors. These are vaporized by exposing the oil to superheated steam at high temperatures.

Historically the most important single use of cottonseed oil has been the manufacture of shortening. There are two general types of

shortening, known in the trade as standard and hydrogenated. Actually hydrogenation is employed to produce both types. For standard shortening a portion of the oil to be used is completely hydrogenated. This converts it to a very hard fat, which then is mixed with a quantity of liquid oil to obtain the melting point and the consistency desired in the finished product. In producing hydrogenated shortening all of the oil is subjected to partial hydrogenation, but the process is carried only far enough to bring the oil to the consistency and the melting point desired in the finished product.

Standard shortening is somewhat less expensive to produce than hydrogenated shortening and sells at a lower price. The latter has superior keeping qualities.

Another important product of cottonseed oil is margarine. In some years more cottonseed oil has been used in margarine than in any other single product. In the manufacture of margarine cottonseed oil is hardened, as in the preparation of hydrogenated shortening, but to a different consistency and melting point. It is then blended with pasteurized skim milk. Salt, vitamins A and D and several minor ingredients are added and the mixture is chilled. The result is a wholesome tablespread similar to butter. Sale of this product has been limited for many years by state and federal restrictions and taxes. However, federal taxes were repealed as of July 1, 1950, and a number of states have also repealed their restrictions upon the product. Production has been increasing since 1940 and the removal of these taxes and other restrictions, it is believed in the trade, will result in a further substantial increase.

Besides shortening and margarine large quantities of cottonseed oil reach the market as salad and cooking oil, salad dressing, and mayonnaise. Some oil also is used as a preservative, especially in canning fish.

Cake or Meal.—Cottonseed cake or meal is a protein concentrate used principally in the feeding of livestock. Most of the farm grains and roughages are deficient in the protein necessary for animal maintenance, growth, and development. The protein concentrates, such as cottonseed cake or meal, provide the means for overcoming this deficiency and also conserve the available supplies of grains and roughages. For example, where cottonseed meal is used only to the extent necessary to balance the ration, 100 pounds of meal will save 250-300 pounds of corn or other grains. Cottonseed meal may be fed without limitation to dairy cattle, beef cattle, horses, mules, and sheep. Because of the peculiar requirements of hogs and laying hens, feeding authorities recommend a mixture of animal and vegetable proteins with cottonseed meal limited to about 9 per cent of the ration for hogs and about 6 per cent for laying hens.

Cottonseed meal is used also to a limited extent as a fertilizer. It is rich in nitrogen and, in addition, furnishes phosphoric acid, potash, and small amounts of minor plant food elements. Being an organic, its plant food elements are released in the soil more slowly than those of the inorganic fertilizers. Meal is suited especially for fertilizing wrapper tobacco, truck, orchard and nursery crops, and lawns.

In general, however, it is more advantageous to feed cottonseed meal to livestock and to apply the animal wastes to the soil. In this way 65

to 85 per cent of the plant food elements contained in the meal can be returned to the soil. Since most of the nutrients removed from the soil when cotton is harvested are contained in the kernel of the seed, the combination of cotton production and livestock is one of the most effective systems for maintaining fertility of the soil.

While cottonseed cake or meal is used principally as an animal or plant food, it also has demonstrated its value as a human food. Prepared from a specially processed cake, a cottonseed flour rich in protein and vitamin B and practically free of starch is produced. Cottonseed flour is not generally available in retail stores, but is marketed principally in the form of bread, cake, cookies, and candies.

Hulls.—Cottonseed hulls are also used primarily as a livestock feed. They differ from cake or meal, however, in that they are a roughage rather than a protein concentrate. In feeding value they are comparable to good grass hay. They can be fed with less waste than hay and, throughout much of the cotton belt, are available at lower cost. Hulls make an excellent carrier for cottonseed meal and grain.

Several industrial uses for hulls also have been discovered. During World War II large quantities of hulls were used in the production of furfural. This is a selective solvent used extensively in the manufacture of synthetic rubber. It also is utilized in the refining of lubricating oils, the purifying of rosin, and the production of certain types of plastics. Hulls are used also to a limited extent in the manufacture of some phenol-type plastics. Generally, however, the demand for hulls for feed has dominated the market and has discouraged their widespread industrial use.

Linters.—Linters have a wider variety of uses than any of the other cottonseed products. The highest grades are spun for use in coarse products, such as twine, wicks, carpets, and gauze. A considerably greater quantity of linters is utilized in the bedding, automotive, and furniture industries, where linters serve as a filler for mattresses and comforts and for upholstery.

Since linters are composed principally of cellulose, this has made them an important raw material of the chemical industries. For chemical usage linters are first purified, a process which involves cooking with certain chemicals, bleaching, washing, and drying. The resulting linter pulp is practically pure cellulose, which is used in many products. In wartime most of the linter pulp is taken for production of smokeless powder. A bale of linters will furnish powder for 100,000 rounds of rifle ammunition, 20,440 rounds of machine-gun bullets, 2,700 anti-aircraft shells, or 85 rounds of heavy-tank ammunition.

The most important peacetime use of linter pulp is the manufacture of rayon. This synthetic fiber enters a wide variety of finished products, ranging from clothing and household items to tire cord and industrial fabrics. Linter pulp is also the basis for a number of the plastics used in such products as automotive and airplane instrument panels, lighting fixtures, radio cases, outdoor furniture, combs, pens, cigarette cases, and shoe heels. Photographic and X-ray film are processed from the same material, as are a group of tough, quick-drying cellulose lacquers.

National Cottonseed Products Association, Inc.,
Memphis, Tenn.

COTTONTAIL. See RABBIT.

COTTONWOOD, kōt'n-wōod, species of *Populus* trees belonging to the willow family (Salicaceae). There are two very common species in North America, *P. balsamifera* and *P. canadensis*. Besides these there are some 15 others, which occur under the names of poplar and aspen (qq.v.). *P. balsamifera* (balsam poplar or tacamahac) has an erect, pyramidal growth and is best planted in a group. The underside of the leaves is dull white. *P. canadensis* (balm of Gilead or Ontario poplar) has a spreading growth and is frequently used in street planting.

COTTONY-CUSHION SCALE. See SCALE INSECTS.

COTTRELL, kōt'rĕl, **Frederick Gardner**: American chemist and mineralogist: b. Oakland, Calif., Jan. 10, 1877; d. Berkeley, Calif., Nov. 16, 1948. Educated at the University of California, where he taught from 1902 to 1911, and at the universities of Berlin and Leipzig, he joined the U.S. Bureau of Mines in 1911, becoming its director in 1920. He was with the U.S. Department of Agriculture from 1922 until 1927 as director of the Fixed Nitrogen Research Laboratory, and thereafter served other governmental agencies, including the Tennessee Valley Authority, in important consultative and research activities.

Subsequent to his research in the field of electrostatic separation of suspensions, he invented the Cottrell electrical precipitator around 1910, which is used to recover such materials as potassium salts and arsenic from smelter flue dust waste (see also ARSENIC). He also conducted studies relating to the recovery of helium and to the liquefaction of gases.

COTYLEDONS, kōt-ĭ-lĕ'dŭns, the seed-leaves of the embryo plant, which serve it as organs of nutrition until the young vegetable is established in the soil and develops its true leaves. In flowering plants there are two kinds of embryos—one in which there is only a single cotyledon, and the other in which there are two cotyledons. This difference, being associated with several others of an important character, serves as the basis for the primary division of phanerogamic, or, more accurately, of angiospermous plants into monocotyledons and dicotyledons. The lower class of plants producing spores or cellular embryos having no cotyledons are called acotyledonous. On germination the cotyledons either serve as foliage-leaves or remain underground as fleshy lobes.

COTYLOSAURIA, kōt-ĭ-lō-sō'rĭ-ā, the most ancient of reptiles, from which, as is claimed by the American naturalist, Edward Drinker Cope and his adherents, sprang the saurian and snakelike species of later ages. Their remains are among the characteristic fossils of the Carboniferous and Permian ages. See also REPTILES.

COUCAL, kōō'kāl, or **LARK-HEELED CUCKOO** (*Centropus*), a genus of common bush-birds in Africa, India and through the Malayan Archipelago to Australia. The hind toe is prolonged into a very long spur. The 35 known species constitute the subfamily Cen-

tropoainae of the cuckoo family (Cuculidae). One species is held in religious veneration in Madagascar.

COUCH. See **QUILLER-COUCH**, ARTHUR THOMAS.

COUCH, Darius Nash, American soldier: b. Southeast, Putnam County, N. Y., July 23, 1822; d. Norwalk, Conn., Feb. 12, 1897. He was graduated at West Point 1846, served in the Mexican and Seminole wars, and resigned from the army in 1855 to engage in business. During the Civil War he was commissioned brigadier-general 1861; commanded a division in the battles of Williamsburg, Fair Oaks, and Malvern Hill; and commissioned major general July 1861. At Fredericksburg and Chancellorsville he commanded the Second Army Corps, organized the Pennsylvania militia to resist Lee's invasion 1863, and took part in the battle of Nashville and the North Carolina operations 1864-1865. In 1865 he was unsuccessful as the Democratic candidate for governor of Massachusetts; and was collector of the port of Boston 1866-1867. He moved to Connecticut soon after, and was adjutant general of that state, 1883-1884.

COUCH GRASS, kouch, a variation of quitch-grass, a perennial grass (*Agropyron repens*) and one of the most common and troublesome weeds of agriculture. When it first appears above ground its blade is readily eaten by sheep. In arable land, under any tolerable management, the seeds are never allowed to ripen, and the propagation is effected by the numerous joints of the long trailing rootstock, each joint sending forth a shoot which becomes a new plant. The proper time for extirpating it is in summer, when the land is undergoing a pure fallow, or, where fallow is not used, when the land is being prepared for a root crop. The rootstock may be used as food for various domestic animals.

COUCY, kōō-sē', CHATELAIN DE, French chevalier; hero of a tragic story often celebrated in ancient ballads and songs, sometimes in connection with other names than his. He became Châtelain of Coucy in 1186, took part in the Third Crusade (1189-1191) and was killed by the Saracens about 1203. His work consists of about 26 songs, in the troubadour style. They were published by Fritz Fath as *Die Lieder des Castellan von Coucy* (Heidelberg 1883).

In a fictitious legend, he was in love with Gabrielle de Vergy, lady of Aubert de Fayel, and dying in the Holy Land, he directed his faithful squire to enclose his heart in a casket and carry it to the Lady of Fayel. He was surprised by the lord of the castle, who found out on what mission he came. Burning with rage, and determined on revenge he ordered the heart to be served at table. The unhappy woman, having eaten, was told the nature of this horrible meal, whereupon she refused all sustenance, and died of voluntary starvation. Uhland has made this story the subject of a fine ballad. The story was first told in verse by Jakemon Sakesep at the end of the 13th century. There is a modern version by Crapelet (Paris 1829, 1895).

COUCY-LE-CHATEAU-AUFFRIQUE, kōō-sē' shā-tō-ō-frēk', commune, France, in the

department of Aisne; 18 miles west-southwest of Laon and 10 miles north of Soissons. Medieval gateways and part of the 13th century walls have been retained. During World War I, the Germans blasted the magnificent castle which had been famous for its robber barons of the 12th century. Industries include flour milling and sugar refining. Coucy gave its name to the famous lords of Coucy. Pop. (1946) 757.

COUDER, kōō-dâr', Louis Charles Auguste, French painter: b. Paris, April 1, 1790; d. there, July 21, 1873. He studied in Paris under de Regnault, David, and later in Munich. Among his works are *Caesar on the Ides of March*; *The Battle of Lawfeld*; *The Opening of the States-General, 1789*; and *The Siege of Yorktown*; the last three are at Versailles. In 1820, he decorated the rotunda of the Louvre with frescoes which were unsuccessful. His decorations of several Parisian churches and his later pictures are decided improvements. As a member of the conseil supérieur at the Ecole des Beaux-Arts he wrote some critical works on art.

COUDERSPORT, kou'dēr-z-pōrt, borough, resort, Pennsylvania. Potter County seat; altitude 1,650 feet; on the Allegheny River; 36 miles east-southeast of Bradford; on the Coudersport and Port Allegany Railroad. It is a mountain resort, in a farming area, producing potatoes and dairy products. The town has a tannery, and industries include the manufacture of toys, surgical appliances, tanning compounds, and silk. The surrounding country offers excellent hunting and fishing. Platted in 1807, the borough was incorporated in 1848. Pop. (1950) 3,210.

COUDERT, kōō-dâr', Frederic René, American lawyer: b. New York, Mar. 1, 1832; d. Washington, D.C., Dec. 20, 1903. He was graduated at Columbia College in 1850, and admitted to the New York bar in 1853. In 1877 he was a delegate of the New York Chamber of Commerce to the Antwerp Congress, which was held for the purpose of establishing a universal system of general average. In 1892 he was appointed one of the counsel on the part of the United States before the Bering Sea Tribunal of Arbitration in Paris, and was specially complimented for his argument on the necessity of putting a stop to pelagic sealing. On Jan. 1, 1896, President Cleveland appointed him a member of the Venezuela Boundary Commission. He was an authority on international law and several times declined appointment to the United States Supreme Court. He was legal representative of France in the United States. He received the cross of the Legion of Honor and decorations from Italy and Venezuela. He wrote *Addresses: Historical-Political-Sociological* (1905).

COUE, kwā, Emile. French psychotherapist: b. Troyes, France Feb. 26 1857; d. Nancy, July 2, 1926. He became famous for his formula "Every day in every way, I am growing better and better." He was a chemist from 1882 to 1910 and a student of hypnotism and suggestion, thereafter establishing a free clinic at Nancy. He taught in Europe and the United States. He emphasized the power of the imagination in the healing of disease and claimed that by this means he could teach people self-healing even to the extent of effecting organic changes.

COUES, kouz, **Elliot**, American naturalist: b. Portsmouth, N. H., Sept. 9, 1842; d. Baltimore, Md., Dec. 25, 1899. Coues' family moved in 1853 to Washington, D.C., where he was educated at Gonzaga Seminary and Columbian University, now George Washington University (A.B. 1861; M.D. 1863; Ph.D. 1869). After the outbreak of the Civil War, he enlisted in the United States Army as a medical cadet and in 1864 was appointed assistant surgeon. During the 17 years of his army service, Coues took every opportunity to cultivate his boyhood interest in birds, making collections and discoveries of new species in the locale of his various assignments, Fort Whipple, Ariz. (1864), Fort Macon, N. C. (1867-1870), and Fort Randall, Dakota (1873). He published his famous *Key to North American Birds* in 1872 and from 1873 to 1876 served as naturalist and secretary of the United States Boundary Commission. Subsequently he wrote *Birds of the Northwest* (1874) and *Birds of the Colorado Valley* (1878), and shared in the preparation of *Check List of North American Birds* (1886). In 1880 he became secretary and naturalist of the Geological and Geographic Survey of the Territories, for whose bulletins he wrote many ornithological papers. He was also one of the founders of the American Ornithological Union and assisted in the editing of its publications.

In addition to his important work in ornithology, Coues wrote *Fur Bearing Animals* (1877); taught anatomy at Columbian University (1877-1886); contributed to the *Century Dictionary*; and edited several works on early western travel, the best-known being *History of the Expedition of Lewis and Clark* (1893). For a brief period (1884-1889) he became interested in psychical research and was active in the Theosophical Society, until violent disagreements led to his expulsion in 1889.

COUGAR, kōō'gēr, a large American cat, generally known as Puma (q.v.).

COUGHLIN, kōg'l'n, **Charles Edward**, American Roman Catholic priest: b. Hamilton, Ont., Oct. 25, 1891. Father Coughlin was ordained in 1916 and 10 years later was sent to Royal Oak, Mich., as pastor of the Shrine of the Little Flower, where, in 1930, he began his rise to national prominence by organizing the Radio League of the Little Flower, through which he broadcast sermons heavily laden with political content. Originally a supporter of the New Deal, he took a violently anti-Roosevelt stand before the 1936 presidential election and organized the National Union for Social Justice, which supported its own candidate, Senator William Lemke. Thereafter he continued voicing his anti-Communist and anti-Semitic opinions, considered by many to be demagogic and fascistic, through his radio broadcasts and his own magazine, *Social Justice*. In 1942, the former were prohibited by his ecclesiastical superiors and the latter was barred from the mails under the espionage law.

COUIY. See **TREE PORCUPINE**.

COULANGES, Numa Denis Fustel de. See **FUSTEL DE COULANGES, NUMA DENIS**.

COULANGES, kōō-lānz'h', **MARQUIS Pierre Philippe Emanuel**, French poet and letter writer: b. Paris, Aug. 24, 1633; d. there, Jan. 31, 1716.

A cousin of Madame de Sévigné, Coulanges is best known as one of the correspondents in the famous *Lettres de Madame de Sévigné*. He served first as counselor and then as master of requests in the French parliament, but gave up public service to travel and to live leisurely in the elegant society of his time. He was a frequent visitor of such prominent women as Madame de Louvois, Madame de Maintenon, the duchess of Richelieu, and many others. He wrote a number of spirited and graceful songs published in *Recueil de Chansons* (1698), as well as letters and his memoirs, the latter of which were published in 1820.

His wife, **MARIE ANGELOUQUE DU GUÉ** (1641-1723), wrote about 50 letters, which rival those of Madame de Sévigné in their richness of spirit and knowledge of the world.

COULOMB, kōō-lōn, **Charles Augustin de**, French scientist and inventor: b. Angoulême, France, June 14, 1736; d. Paris, Aug. 23, 1806. The author of important studies in magnetism, electrostatics, and friction, Coulomb is best known for his invention of the torsion balance and his formulation of principles for measuring the force of magnetic and electrical attraction (see **COULOMB'S LAW**). In early life he entered the engineers' corps and served for some time in the West Indies. His treatise, *Théorie des machines simples*, dealing with the subject of friction in machinery, was published in 1779.

Coulomb became a member of the French Academy in 1781 and three years later was appointed superintendent of the waters and fountains of France. During the first part of the Revolution he retired from public activity to devote himself to research, but later took part in the new government's project of a metric system of weights and measures and in 1802 was appointed inspector of public instruction. See also **COULOMB**.

COULOMB, the unit of quantity in measuring electric currents. It is the quantity produced by a current of one ampere in one second. It was named for its discoverer, Charles Coulomb (q.v.) by the International Congress of Electricians in 1884.

COULOMB'S LAW, in physics, the law of interaction between two electric charges or two magnetic poles, demonstrated by Charles Augustin de Coulomb (q.v.). This law, which is similar to Newton's law of gravitation for the interaction between portions of matter, states that the force exerted between two electric or magnetic charges is directly proportional to the product of the charges, and inversely proportional to the square of the distance between them.

COULOMETER, kōō-lōm'ê-tēr (sometimes called a **VOLTAMETER**, vōl-tām'ê-tēr), a term applied to a device designed for measuring, by electrochemical means, the quantity of electricity in coulombs passing through an electrical circuit. Actually it measures the amount of electrolysis produced by the current in the electrolytic cell. The so-called "silver coulometer" has the largest acceptance among scientific laboratories. It was formally adopted by the International Electrical Congress, held in Chicago in 1893, as the most dependable of all the coulometers for the official measure of the efficiency of

an electrical current, the international ampere. For the construction of such a cell, consult Rosa, E. B., and Vinal, G. W., *Bulletin*, Bureau of Standards. vol. 13, p. 479 (Washington, D.C., 1916).

COULOMMIERS, kōō-lō-myā', town, France, in the department of Seine-et-Marne, 14 miles southeast of Meaux. It is situated on the Grand Morin River in an agricultural region yielding fruits, flowers, and dairy products. Coulommiers is famous for the manufacture of its Brie cheeses; other industries include sugar milling and metal processing. The old Church of St. Denis, whose choir and apse date from the 13th century and whose nave dates from the 16th century; the ruins of an early 17th century castle; and the birthplace of the French painter Jean de Boullongne, called le Valentin (1591-1634), are places of interest in the town. Coulommiers was damaged during World War I, but escaped bombing in World War II. Pop. (1946) 6,302.

COULTER, kōl'tēr, **Ellis Merton**, American historian and educator: b. near Hickory, Catawba County, N. C., July 20, 1890. After graduating from the University of North Carolina (1913), he received his master's degree (1915) and doctorate (1917) from the University of Wisconsin, where he also taught history. His career as an educator, begun as a high-school superintendent at Glen Alpine, N. C., was continued in teaching positions at Marietta College, Ohio, and at the University of Georgia, where he was appointed full professor in 1923. His publications on the old South, the American Civil War, and the period of reconstruction have been important contributions to the historical literature of the southern United States. He wrote *The Civil War and Readjustment in Kentucky* (1926); *College Life in the Old South* (1928; rev. ed. 1951); *A Short History of Georgia* (1933; rev. ed. 1947); *John Jacobus Flournoy, Champion of the Common Man in the Antebellum South* (1943); *The South During Reconstruction 1865-1877* (1947); and *Confederate States of America, 1861-1865* (1950).

COULTER, kōl'tēr, **Ernest Kent**, American lawyer and humanitarian: b. Columbus, Ohio, Nov. 14, 1871; d. Santa Barbara, Calif., May 1, 1952. Coulter was educated at Ohio State University (B.A. 1893) and at New York Law School (LL.B. 1904) and thereafter practiced law in New York, where he founded the Big Brother Movement (q.v.), a group of volunteer workers to aid in the rehabilitation of delinquent boys. He was also an organizer of the Children's Court of New York (1902-1912) and general manager of the New York Society for the Prevention of Cruelty to Children (1914-1936). He was the author of *The Children in the Shadow* (1913), which he describes as "the story of three delinquents, the child, the parent, and the community, as it comes from the new but greatest social clinics in the world, the Children's Courts."

COULTER, John Lee, American economist and statistician: b. Mallory, Minn., April 16, 1881. Educated at the University of North Dakota (B.A. 1904; M.A. 1905; LL.D. 1922) and at the University of Wisconsin (Ph.D. 1908), Coulter was an instructor successively from 1907

to 1909 at Iowa State College, the University of Wisconsin, and the University of Minnesota, where he also served for two years as assistant professor of rural economics. From 1921 to 1929 he was president of the North Dakota Agricultural and Mechanical College. Coulter's chief contribution was his service as special agent of the United States Census Bureau (1910-1912) and as chief economist and chairman of the advisory board of the United States Tariff Commission (1929), on which he served as a member until 1934. He was the author of *Economic History of the Red River Valley of the North* (1910); *Cooperation Among Farmers* (1911); and *Postwar Fiscal Problems and Policies* (1945).

COULTER, John Merle, American naturalist: b. Ningpo, China, Nov. 20, 1851; d. Yonkers, N. Y., Dec. 23, 1928. A graduate of Hanover College, Ind. (B.A. 1870; M.A. 1873), Coulter was employed by the United States Geological Survey (1872-1873) as a botanist in the Rocky Mountains and subsequently as professor of natural science at Hanover (1874-1879). At Wabash College, Ind., where he received his doctorate (1884), he was professor of biology from 1879 to 1891. In the latter year, Coulter was named president of Indiana University and also professor of botany there. In 1893 he became president of Lake Forest University and three years later moved to the University of Chicago as professor of botany and head of the botany department. From 1895 until his death he was connected with the Boyce Thompson Institute of Plant Research at Yonkers.

One of the outstanding American botanists of his generation, Coulter served as president of the American Association for the Advancement of Science in 1918 and was a member of the National Research Council from 1923. For many years he edited the *Botanical Gazette*, which he helped to found in 1875. Among his publications were *Manual of Rocky Mountain Botany* (1885); *Manual of Texas Botany* (1891); *Plant Relations* (1899); *Plant Structures* (1899); *Plant Studies* (1902); *A Textbook of Botany* (1906); *Elementary Studies in Botany* (1913); *Evolution of Sex in Plants* (1914); *Fundamentals of Plant Breeding* (1914); and *Plant Genetics* (1918). He also edited the 6th edition (1890) of Gray's *Manual of Botany* and, in collaboration with Charles J. Chamberlain, wrote *Morphology of Gymnosperms* (1901) and *Morphology of Angiosperms* (1903).

His brother, **STANLEY COULTER** (b. Ningpo, China, June 2, 1853; d. Lafayette, Ind., June 26, 1943), was professor of biology and director of the biological laboratory at Purdue University (1887-1926), where he also served as dean of the school of science (1907-1926) and dean of men (1919-1926). His publications include *Forest Trees of Indiana* (1892); *Flora of Indiana* (1899); and *A Key to the Genera of the Native Forest Trees and Shrubs of Indiana* (1907).

Consult Rodgers, A. D., *John Merle Coulter, Missionary in Science* (Princeton 1944); Banta, Richard E., *Indiana Authors and their Books, 1816-1916* (Crawfordsville, Ind., 1949).

COUMARIN (also CUMARIN), kōō'mā-rin, a chemical substance used as a fixative in perfumery (see PERFUMES AND PERFUMERY—*Ingredients and Extraction Processes*). It has the formula $C_9H_6O_2$, and is prepared in the form of crystals, flakes, or powder. The finer grades

are derived from the Tonka bean, but it is also obtained by heating salicylic aldehyde, sodium acetate, and acetic anhydride. It was banned in the United States as a food flavor in 1953.

COUMARONE, kōō-má-rōn (also CUMARONE, or BENZOFURAN), a substance derived from coal tar, which is used in making synthetic resins. It is a colorless liquid, soluble in alcohol or ether but insoluble in water, and has the formula C_8H_6CHO .

COUNCIL (Lat. *concilium*), an assembly met for deliberation, or to give advice. The term as used in an ecclesiastical sense specially applies to certain assemblies of the Roman Catholic Church. These may be classed as ecumenical, provincial or patriarchal councils and synods; but the last is not usually included among councils. An ecumenical or general council is one in which the bishops and others entitled to vote are convoked from the whole world to deliberate on the state of the Church or to meet an emergency, as the rise of a new heresy. The decrees of such a council, having received papal confirmation, are binding. A council might be ecumenical in its convocation, yet if its decrees did not receive the papal confirmation they would not be binding, and the council would not be considered of ecumenical authority. Or a council might not be ecumenical in its convocation, but its decrees being accepted and receiving the papal confirmation, it is then classed as ecumenical. The First Council of Constantinople was originally a council of the East, but ultimately its decrees on faith were accepted in the West and received the confirmation of the Pope. Patriarchal councils represent a whole patriarchate; national councils, a nation; and primate councils, provinces subject to a primate. (See PATRIARCHS). Provincial councils are of a province and are known usually by the name of the metropolitan see. (See METROPOLITAN). Diocesan councils, usually termed synods, are composed of the clergy of the diocese and are presided over by the bishop or vicar-general or a representative of the bishop.

Ecumenical councils are convoked by the Pope, and are under his presidency or that of his legate. In the early ages of Christianity councils were sometimes convoked by emperors, but only by permission or by request of the Pope. The dangers and difficulties of traveling in those times made it necessary to have the protection of the civil powers, and hence the real part which the emperor took in convoking the council was to promise it immunity from those who might wish to influence or retard its deliberations. The patriarch, metropolitan or bishop convokes the council within his jurisdiction. The membership of councils not ecumenical consists of the local clergy, as in a diocese, or the suffragan bishops of a province or patriarchate. Certain rules regulating representation are observed. In the early ages (and even as late as 1598), laymen were sometimes invited to attend provincial councils. They were permitted to present complaints and give advice but it is very doubtful if they ever took any part in the voting. In two instances at least women attended. (See HILDA, SAINT). Ecumenical councils are composed of patriarchs, archbishops and bishops and such

other ecclesiastics as may be invited for specified reasons, as theologians, one at least for each archbishop or bishop. (The Council of Trent gave procurators—priests and deacons—of absent bishops a right to vote. The Vatican council did not even admit to the council hall such procurators). In matters of faith the Holy Scriptures and the traditions of the Church are the guide, while in lighter matters human reason and expediency are consulted. In the former, ecumenical councils are held to be infallible, but in other matters of discipline, etc., the latest council decides questions. Cardinals, even if not bishops or abbots, generals of regular orders, mitred abbots of whole orders, may be members with right to vote. The rule has always prevailed that no royal representative may be present at any council except a general one in which "faith, reformation and peace" are in question.

The presidency of a council does not confer an ex officio right to vote or to take part in the deliberations, such right depending upon the hierarchical rank of the one presiding.

Usually bishops take their places according to the rank of their sees. At the Vatican council they were arranged according to their hierarchical rank,—first the Pope, then the cardinals, patriarchs, primates, archbishops, bishops, abbots and generals of orders. The voting is generally by single vote, but at Constance the vote was by nations. At Basel the members were divided into four deputations which met separately. Decrees passed by three deputations were accepted by all. At Trent much of the matter to be debated was first considered by commissions. (See COUNTER-REFORMATION). The proceedings of the Vatican council, not yet finished, were conducted in a somewhat similar manner.

Church historians usually regard the assembly of the apostles in Jerusalem described in the Acts of the Apostles as the first example of a general council of the Church; yet that assembly is not entered in the list of the 20 general councils. From the times immediately subsequent to the epoch of the apostles, the fathers always on occasion of controversy over questions of faith or of discipline appeal to the tradition of the apostolic doctrine and government as preserved in the churches founded by the several apostles or authentically derived thence, to the churches scattered over the world. Not till peace was assured to the Christian body by Constantine was it deemed prudent to hold a general assembly of the Church's pastors, the bishops; though in various provinces of the empire—in Gaul and Spain, in Mesopotamia, in Africa, synods or councils were held even in the times of persecution. But in the year 325 there assembled at Nicaea in Bithynia, at the call of the emperor, the first or Nicene council. As this council and many which followed were in their membership predominantly Eastern, so in later councils Western bishops predominated; and for some time the decrees of these predominantly Eastern, or predominantly Western, councils were not accepted by both sections; but in time many of them received a tacit acceptance as expressing the teaching of the whole Church Catholic; while the decrees of other Eastern and other Western churches are ignored on one side or the other.

The general or ecumenical councils of the

Church, as reckoned by Roman Catholic historians, are as follows:

	A.D.
1. Council of Nice (<i>Nicaea</i>)	325
2. First Council of Constantinople	381
3. Council of Ephesus	431
4. Council of Chalcedon	451
5. Second Council of Constantinople	553
6. Third Council of Constantinople	680
7. Second Council of Nice	787
8. Fourth Council of Constantinople	869
9. First Council of Lateran	1123
10. Second Council of Lateran	1139
11. Third Council of Lateran	1179
12. Fourth Council of Lateran	1215
13. First Council of Lyons	1245
14. Second Council of Lyons	1274
15. Council of Vienne	1311-1313
16. Council of Constance	1414-1418
17. Council of Basel	1431-1438
Council of Basel continued in Council of Ferrara-Florence	1438-1442
18. Fifth Council of Lateran	1512-1517
19. Council of Trent	1545-1563
20. Council of the Vatican (not finished)	1869

Of these councils the Greek Church acknowledges the first seven. See separate accounts of the different ecumenical councils.

Among religious bodies of the Protestant faith the word council is applied to assemblies lacking the authoritative form of the Roman Catholic councils. In the Baptist and Congregational denominations it is customary to use the term council in relation to gatherings called on matters of local or restricted interest or in connection with ordinations or other church functions. A national council in these denominations is advisory in its nature. The Pan-Presbyterian Alliance is in the nature of a council of churches following the Presbyterian form of organization and holding the Reformed faith. The Evangelical Alliance (q.v.) is broad and inclusive in its constituent elements and in the themes considered. In the systematic nature of their organizations and the authoritative character of their decisions the councils of the Roman Catholic Church are more nearly related to the permanent governing bodies of evangelical sects charged with the regulation of faith, order and discipline—such as the general and diocesan conventions of the Protestant Episcopal Church, the general assemblies and synods of the Presbyterian Church, and the general conferences of the Methodist Church.

In its use as a term relating to civil government, the word council signifies a body of men selected to advise a sovereign or other ruler. The body exercising such functions in Great Britain is known as the privy council (q.v.). In colonial times there existed in America councils modeled on the English privy council and originally intended as the executive bodies of the various provinces, in conferences with the respective governors. Such a body was called the executive council or legislative council, or simply the council. As the legislatures developed into the bicameral form in which we now know them, the upper house kept the name council until long after the Revolution; in South Carolina until 1790; in Delaware until 1792; in Georgia until 1798 and in Vermont until 1836. The territories have retained the name, and it is used in some states for a body like that in the old provinces, the executive council of the governor.

Bibliography.—The earliest authoritative history of the church councils is that of Jean Hardouin, *Conciliorum collectio regia maxima* (Paris 1715), and the best history

is that of C. J. Hefele, *Koncilien Geschichte*, 8 vols. (Freiburg 1855-1890) with appendages by P. Richard and A. Michel. Consult also Labbe, P., *Conciliorum omnium collectio studio*, 23 vols. (Venice 1728-1733); Mansi, G. D., *Sacrorum conciliorum et decretorum nova et amplissima collectio*, 31 vols. (Florence and Venice 1759-1798); Hinschius, P., *System des katholischen Kirchenrechts*, vol. 3 (Berlin 1869); *Acta et decreta sacrorum conciliorum recentiorum*, ed. by the Jesuits of the Abbey of Maria-Laach, Germany (Freiburg 1870-1890); Bliemetzrieder, F., *Das Generalkoncil im grossen abendländischen Schisma* (Paderborn 1904); Eisele, Josef A., *Die Rechtsstellung des Papstes im Verhältnis zu den allgemeinen Konzilien* (Emsdetten, Germany 1938).

COUNCIL BLUFFS, city, Iowa, and seat of Pottawattamie County, on the east bank of the Missouri, opposite Omaha, Nebraska, at an altitude of 984 feet, and served by the Union Pacific, the Chicago and North Western, the Wabash, the Chicago Rock Island and Pacific, the Missouri Pacific, the Illinois Central, the Chicago Great Western, and the Chicago, Milwaukee, St. Paul and Pacific railroads, and on four federal and two state highways.

The city is well laid out on a plain underlying high bluffs, and is connected with Omaha by Bridges over the Missouri. Transport lines connect it with Lake Manawa State Park, a beautiful summer resort three miles south of the city.

Industry.—Council Bluffs is one of the great agricultural implement trade centers of the world and manufactures as well tools, railroad equipment, batteries, truck bodies, machinery, elevators, livestock remedies, playground equipment, radio parts, canvas, feed, and soft drinks. It is a railroad terminus point and has railway repair and maintenance shops.

History.—The name of the city came from a council held 20 miles north of Omaha in 1804 between the Indians and the explorers Meriwether Lewis and William Clark. However, the city's name had once been changed from Hart's Bluff to Kanessville by the Mormons who early came to settle here. In April 1847 the Mormons were expelled from the city to become the pioneers of Utah, and in 1849 Kanessville was an important outfitting point for travelers to the California gold fields. The name was officially changed to Council Bluffs in 1852 and a year later the city was incorporated. In 1863 it became the terminus for the Union Pacific Railroad and there is a Golden Spike Monument here to commemorate the occasion. The city is governed by a city manager and council. Pop. (1950) 45,429.

COUNCIL GROVE, city, Kansas, seat of Morris County, at an altitude of 1,234 feet, situated on the Neosho River, 129 miles northwest of Parson, and served by the Missouri, Kansas and Texas, and the Missouri Pacific railroads. In a rich dairy, poultry, and grain region, it has a dairy and poultry products processing plant, flour mills, grain elevators, and machine shops.

An Indian treaty made here in 1825 permitted the survey of the Santa Fe Trail, to which the place owed its growth until 1866 when the railroad came through. Its Methodist Indian mission (built in 1849 and still standing) was the site of the first white school in Kansas. Another building, the Last Chance Store, built in 1857, still stands as a monument. Pop. (1950) 2,722.

COUNCIL OF WAR, an assembly of officers of high rank called to consult with the commander in chief of an army or admiral of a fleet on matters of supreme importance. The commandment of a garrison will accept or generally solicit the advice of such a council before surrendering to an enemy.

COUNCILL, William Hooper, Negro educator: b. Fayetteville, N. C., July 12, 1848; d. Normal, Ala., 1909. Born a slave on a North Carolina plantation, he received after the Civil War three years of education in a school in Stevenson, Ala. (1865-1867) and held the positions of chief enrolling clerk in the Alabama House of Representatives (1872-1874), and receiver general in the land office of the Northern District, Alabama (1875). He was the organizer and the first president of the Agricultural and Mechanical College (now the Alabama A. and M. College), at Normal, Ala. He was the founder and editor of the Huntsville *Herald* from 1877 to 1884 and became a member of the Supreme Court of Alabama in 1883.

COUNCILMAN, William Thomas, American physician: b. Pikesville, Md., Jan. 1, 1854; d. May 26, 1933. He was educated at the University of Maryland, and at Vienna and Leipzig, was for some time associate professor of pathology in Johns Hopkins University, and became Shattuck professor of pathological anatomy at Harvard University in 1892. He devoted much study to smallpox, and announced his discovery of the probable etiology of smallpox. He published monographs on dysentery, cerebrospinal meningitis, diphtheria, and smallpox.

COUNSEL, the advice given as to a proposed line of conduct, claim, or contention; also a legal practitioner. In a narrower sense, the term is sometimes used to describe a lawyer who specializes in giving advice on the preparation and management of lawsuits, and in appearing in court to conduct trials, argue cases, or present motions. In this usage, "counsel" is more restricted than "attorney at law" (q.v.), since the latter includes anyone who engages in any of the branches of the practice of law, whether or not he appears in court or engages in the preparation of cases. A distinction was formerly made, in common terminology, between "counsel" and "attorney at law," analogous to the British distinction between "barrister" and "solicitor." At the present time, however, there is no practical distinction between the two terms in the United States.

COUNSELOR AT LAW. See ATTORNEY AT LAW.

COUNT, a title of dignity, derived from the Latin *comes*, literally, companion. Historically, in the early Roman Empire, the word *comes* meant simply attendant. Later, as the emperors surrounded themselves with many *comites*, they gained power through official duties. Under Hadrian they formed a permanent council, and the designation *comes* became a formal official title. During the reign of Constantine, 10 out of 35 provincial generals received the title of *comes*. After the fall of the Roman Empire the title was retained by the conquerors; later under Charlemagne it denoted equally military or civil employment.

After the Franks became the ruling nation, the king made appointments with jurisdiction over certain districts which carried the title of *Grafen*. The German title *Graf* corresponds to the title "count" and the office of *grafio* was often designated by the Latin *comes*. In France the count of the palace (*comes palatii*) had, by the 11th century, acquired rank apart from that of the other counts. The title has never been used in England although its Latin equivalent has been the common translation for "earl," and the wife of an earl has always been designated a "countess."

Under the Carolingian kings of France the institution of countship was maintained and strengthened; but the feudal evolution changed the status of counts from representatives of royalty clothed with military, political, judicial and financial responsibilities to hereditary lords who were vassals of the king and no longer functioned as his representatives. In medieval and Renaissance times the importance of the title varied. Some counts, like those of Flanders and Champagne, enjoyed greater prestige and power than most marquises and dukes, while others were little more than country squires. This title, with all other nobiliary and royal titles, was suppressed by Revolutionary France but reappeared under the Empire. In present-day Republican France

many individuals having the hereditary right to call themselves counts and countesses ignore their titles. In general it may be said that in France whatever social prestige attaches to a title depends on the luster of the family tradition, not on the title.

Since medieval times Italy has been able to boast a greater number of counts than any other region of Europe, due to the fact that popes and princes granted the title of *conte* indiscriminately. There being no strict rule of primogeniture or regulating authority for titles, the number of such *conti* has always included many persons having no legitimate right to any title. The papal title is still given as a reward for services to the Roman Catholic Church. In Italy, whatever social value exists in a countship, as in France, depends on the eminence of a family tradition, not on its title. The Spanish title of *conde*, however, carries considerable prestige, because the law of primogeniture is strictly observed and the government exacts a fee on the inheritance of a title. Like other Spanish titles, that of *conde* may be transmitted through the female line. See also TITLES.

COUNT OF MONTE CRISTO, The.

A typical novel of the romantic period in France was *The Count of Monte Cristo*, by Alexandre Dumas, written from 1841 to 1844 with the assistance of two minor collaborators, Auguste Maquet and P. A. Fiorentino. It was begun before and completed after the equally famous *Three Musketeers*, from which it differs in being more melodramatic and intense, less natural and humorous. The protagonist, Edmond Dantès, bears the earmarks of the romantic hero of the Byronic poems, although he is not so sentimental, being endowed with an active passion that sets him wrestling with superhuman difficulties instead of brooding over them in sick despair. Dantès is the victim of unscrupulous enemies, a gloomy giant outraged by society. Unjustly confined within the dungeons of the Château d'If, he learns from a fellow prisoner the arts and sciences, and the secret of a buried treasure. When his companion dies, Dantès, assuming the rôle of the corpse, is flung into the sea and swims to freedom. He recovers the lost treasure, and, as the possessor of immense wealth, proceeds to work out his elaborate schemes for mysteriously rewarding those who have been his benefactors, and wreaking vengeance upon those who are responsible for his misfortunes. He is ruthless in his pursuit of these enemies, insinuating himself unsuspected into their good graces, and leading them on by diverse paths to destruction.

COUNT ROBERT OF PARIS, a novel by Sir Walter Scott (q.v.), first published in 1831, the year before his death. Together with *Castle Dangerous*, it was reissued the following year as the fourth series of *Tales of My Landlord*, the two works constituting the last productions from the author's pen. The story is set in Byzantium, at the court of Emperor Alexius Comnenus, during the time of the First Crusade (1096-1099). The leading characters in the novel are Count Robert; his wife Brenhilda; Hereward the Saxon; and Nicephorus Briennius (properly Bryennius), the emperor's son-in-law, who is engaged in a conspiracy to supplant the monarch. Godfrey of Bouillon and other leading Crusaders also appear.

COUNTER REFORMATION, the movement within the Roman Catholic Church to correct abuses, to raise the moral and spiritual level of both clergy and people, to improve administrative personnel and procedure, and, in view of existing needs, to make and put into effect an authoritative statement of belief and practice. Beginning in the second decade (1527-1537) of the Protestant Reformation, it lasted for more than a century. Both Reformation and Counter Reformation are unsatisfactory terms. The former names a definite break with the Catholic Church and the establishment of the new Lutheran, Calvinist, and Anglican systems, all differing essentially in doctrine, organization, and practice from the Catholic system, and in various ways from one another. The latter names a movement only secondarily directed against the Protestant bodies. Primarily it was a process taking place within the church: an inner purging of ills and a restoration to health and vigorous action.

In antecedents the two movements had certain things in common. For the Catholic reform, the principal events and conditions inducing its need include the following: the weakening of large sections of the clergy in education and character after the devastation wrought by the Black Death; faults and aberrations in some forms of popular devotion; corruption among some of belief and morals attendant on the pagan elements in the Renaissance; defects and abuses within the church's administrative departments; decline of loyalty to the Holy See; the emergence of the powerful secular state; decadence in the field of traditional theology and philosophy; and finally the urgent challenge of the Protestant triumph in much of northern Europe, together with its threat to make still further conquests.

The movement was chiefly under the leadership of a succession of outstanding popes, aided by a diversified group of great saints, such as Charles Borromeo and Ignatius Loyola, and various other religious and civil leaders. This multifaceted work of reform and revival had its beginnings in the brief reign of the Dutch Pope Adrian VI (1522-1523), only to be delayed by the disastrous pontificate of Clement VII (1523-1534). His successor, Paul III (1534-1549), immediately began plans for a general council of the church, but it was not until December 1545 that the first sessions of the 19th ecumenical council were held. For over 18 years, but with long interruptions, the epochal Council of Trent (q.v.) continued its work. Among doctrinal subjects upon which decrees were issued were those of Sacred Scripture, tradition, original sin, the Mass, and the sacraments; among disciplinary matters was legislation on clerical education, ecclesiastical benefices, and requirements for episcopal residence. Not the least of its effects was the issuance of the Roman Catechism, with a consequent improvement in religious instruction.

Seven popes continued the work begun by Paul III: Julius III (1550-1555), Marcellus II (1555), who as Cardinal Marcello Cervini degli Spannochi had taken a leading part at Trent, Paul IV (1555-1559), Pius IV (1559-1565), St. Pius V (1566-1572), Gregory XIII (1572-1585), and Sixtus V (1585-1590). Especially noteworthy were the changes made by Paul IV in the papal court. Under him and St. Pius V almost the last vestiges of what was most harmful in Renaissance thought and conduct were erased from the Roman curia.

The reform of old communities and the estab-

lishment of new orders were an important part of the movement. Among reformed communities the Capuchins, an autonomous Franciscan group, made great contributions by their preaching, charitable work, and missionary activities. In Spain, under the leadership of St. Theresa of Avila and St. John of the Cross, great as organizers and writers as well as mystics, the Carmelites began a remarkable revival. The Theatines were established in 1524 by St. Cajetan of Thiene and Giovanni Pietro Caraffa (the future Paul IV). In 1564 the Oratorians were founded by St. Philip Neri. Most famous and influential of all was the Society of Jesus. Established by St. Ignatius Loyola in 1540, the Jesuits soon became leaders in almost every field. St. Francis Xavier, St. Peter Canisius, St. Aloysius Gonzaga, St. Francis Borgia, St. Robert Bellarmine, James Lainez, Edmund Campion, and Robert Parsons (or Persons) are only a few of the outstanding figures in the society's first century.

The results of this immense surge of prayer and labor on the part of many-sided geniuses in both high and low places, the leadership which they offered, and the response given by great masses of the people appeared in various ways. The advance of the new religions was halted, especially in Poland and Germany; in other places, where the issue was still in doubt, the church at length prevailed. In England the Catholic forces were rallied and a foundation on which to preserve the faith among Catholics and to bring converts into the church was laid. Missionaries were sent into the New World and to the East. Not only was there moral reform, but also to devotion and spirituality were given a new direction and a sounder basis. In this last work two names are pre-eminent: St. Francis de Sales, with his *Introduction to the Devout Life*, and St. Ignatius Loyola, with his *Spiritual Exercises*.

So great a resurgence of life and vigor necessarily had its impact upon the arts. Masterpieces of later Renaissance and mannerist architecture; the glories of the baroque style, which has been likened to a mighty shout in praise of God; and the music of such men as Palestrina and Victoria can be understood only in this reference. Productions in painting and sculpture by El Greco, Tintoretto, Bernini, and countless others reflect the spirit of this era of strenuous faith. Literature too had its part, especially in Spain. Suarez, John of St. Thomas, Dominic Soto, Thomas Stapleton, and Bellarmine appear in philosophy and theology. Like the rise of Protestantism, the Catholic reform was crucial for the history of Europe and the world. As a great constructive effort, its effects have been so deep and pervasive that, despite vast changes which ensuing centuries have effected, they are still felt throughout the church and the world.

COUNTERFEITERS. The (*LES FAUX-MONNAYEURS*), which first appeared in French in 1926, is the only one of André Gide's works he is willing to designate as a novel. Various called his masterpiece, a novelist's novel, and a distinguished failure, it is a complex fiction of over 500 pages embodying 28 characters. At least four principal themes are interwoven in a contrapuntal composition inspired by Bach, and borrowed in Aldous Huxley's *Point Counterpoint*: the counterfeit existence most people lead (more significant to the title than the youthful circulators of false coinage who figure in the plot); the decay of the middle-class family represented by those of the two judges, Profitendieu and Molinier, and the Protestant minister, Vedel; the conflict between the generations; and, finally, the creation of the work of art. By placing at the center of the action the novelist Edouard, who, much like his creator but without his genius, is trying to write the very novel we are reading, Gide throws extraordinary light upon all the themes. For Edouard is closely related to the Moliniers and has lived in the Vedels' boarding school; by age he belongs to the parents' group and by temperament and affection to that of the children. Deeply moved by his nephew, Olivier Molinier, he takes Bernard Profitendieu as his secretary; this is but one of the counterfeit substitutions.

Haunted by the technique of the story within a story, which he finds in *Hamlet*, in Poe's *Fall of the House of Usher*, and in Goethe's *Wilhelm Meister*, Gide here makes his best use of it. Edouard sees two centers to his novel: the event and the effort to make it into art, and this is precisely what Gide, himself, gives us. Hence his consistent use of what he calls indirection: events are related, ideas expressed, and characters described by the characters themselves in their conversations, journals, and letters. The reader, who consequently seems to know more than the author, must collaborate with him to reconstruct the truth. Gide, remaining aloof, is thus able to comment dispassionately upon action and characters as Fielding and Sterne have done. Such a technique, added to the novelist's refusal to take advantage in one chapter of the impetus accumulated in the preceding one, achieves the fascinating variety and confusion of life itself. Like the adolescent heroes who stand at its center, the novel indeed is in a state of becoming before our very eyes, and, despite the climatic episode of a schoolboy's suicide, it ends with the suggestion that it could be continued. Such a novel calls for most attentive reading, but has not Gide said that he writes to be reread?

A suicide and two unsuccessful attempts, a glorification of the bastard, and a sympathetic, natural presentation of uranism are sufficient to alienate moralistic readers. Indeed, even the Devil tiptoes incognito throughout the novel, occasionally appearing visibly to those who believe in him. For, like Dostoyevsky, on whom he gave a series of stimulating lectures while writing this novel, Gide enjoys challenging conventional morality and psychology. Early in his career he recognized that his function was to disturb and that none of his books would leave the reader intact.

JUSTIN O'BRIEN,
Professor of French, Columbia University.

COUNTERFEITING. The making of bogus currency, coins, or other obligations, and

in the broad sense, the fraudulent circulation of such—is one of the oldest of crimes against the sovereign state. The seriousness with which this offense against the people has been regarded throughout the ages is attested by the fact that at times in various lands it has been punishable by death.

History indicates that this crime of counterfeiting has existed almost from the time that a circulating medium of exchange was devised. History itself has been influenced in several instances when counterfeiting was engaged in on a large scale, or when it was instigated as a method of economic or actual warfare.

The still common expression «Not worth a Continental,» to denote worthlessness, dates back to the American Revolution when counterfeiting contributed to the devaluation of Continental currency. In 1789 the French Revolutionary government issued currency known as assignats. By 1796 the enemies of the revolution had circulated billions of francs in counterfeit assignats, and the currency became valueless. It subsequently was repudiated by the government.

In 1812 Napoleon Bonaparte, Emperor of France, is said to have purchased military supplies for his invasion of Russia with counterfeit money produced at a printing plant he established in Paris.

In the United States, the power to provide punishment for counterfeiting is vested in the Congress under Section 8 of the Constitution, and the federal agency charged with the suppression of counterfeiting is the United States Secret Service, a branch of the Treasury Department. (See SECRET SERVICE, UNITED STATES).

Prior to 1860 Congress had passed several laws with respect to counterfeiting, but had provided no funds for the enforcement of those laws because the paper currency in circulation was privately printed by individual banks in some 3,000 different designs, and there was no standard federal paper money. In 1860 an appropriation of \$10,000 was made for the purpose of detecting and bringing to trial persons engaged in the counterfeiting of coins.

An act of 25 Feb. 1862, authorized the issue of \$150,000,000 in United States notes, not bearing interest and payable to the bearer. They were legal tender for all debts except duties on imports and interest on the public debt, and were popularly referred to as «greenbacks.» The act of 3 June 1864, known as the National Bank Act, supplementing an original act of 25 Feb. 1863 (see BANKS AND BANKING—*The National Banking System*), is the basic act for the national banking system, and provided for the organization of national banks and the issuance of circulating notes. These notes were drawn on the various national banks, but were issued under government supervision on the strength of collateral furnished by the banks in the form of United States interest-bearing registered bonds. With the adoption of the federal currency in the form of United States notes and national bank notes, the private bank notes became obsolete and the government necessarily acted to protect the new money against counterfeiting. In 1864 the sum of \$100,000 was made available for the suppression of counterfeit currency and other forms of obligations of the United States.

During the period 1860 to 1865 the solicitor of the Treasury had supervised the operations of persons who furnished information on counterfeiting and had approved payments made to them. However, the new federal currency was counterfeited so extensively that it became necessary to make a definite and centralized effort to suppress these violations and to restore and maintain public confidence in the new money. Accordingly, on 5 July 1865, Hugh McCulloch, then Secretary of the Treasury, created the United States Secret Service, and this agency has since been responsible for the prevention and suppression of counterfeiting in the United States.

These first Secret Service agents, in addition to following traditional investigative methods, developed certain distinctive techniques designed to identify, arrest and convict counterfeiters, and to locate and destroy their plants. The service, one of the oldest federal law enforcement groups, makes full use of all the modern developments in scientific crime detection; and, in addition, beginning in 1937, pioneered a novel approach to prevention of crime through educational methods. The theory of this new method is that the passing of counterfeit money can be made too dangerous to be profitable by teaching handlers of money, including the general public, how to distinguish good money from bad. Special training has been brought to bank employes and other commercial handlers of cash, and an effective system for speedy dissemination to such agencies of warning notices and details of new counterfeits as they appear has been one phase of this program. In addition, under the slogan, «Know Your Money,» instruction in the detection of counterfeits has been carried to the general public through the schools, through motion pictures, radio, lectures, and newspaper and magazine articles.

The volume of counterfeit money circulated in the United States has fluctuated widely through the years. The peak appears to have been reached in the middle 1930's when several large gangs organized extensive operations from plants set up in the eastern part of the nation. Representative value of bogus bills and coins seized in several of these years exceeded \$1,000,000. The destruction by the Secret Service of these gangs, and the conviction and sentencing to long prison terms of scores of the bogus money circulators brought a substantial reduction in such losses to the public. The amount of spurious bills and coins seized has continued drastically downward in recent years, and the total for the fiscal year ended 30 June 1944, was only \$47,060. The Crime Prevention Program of the Secret Service, stringent enforcement efforts and other factors have contributed to this marked decline in the crime of counterfeiting.

It is not difficult to distinguish good money from bad. Genuine bills are printed from engraved steel plates produced by master craftsmen at the Bureau of Engraving and Printing in Washington, D.C. Most counterfeit bills, however, are printed from copper or zinc plates upon which the impressions of the bills have been etched with acid.

The feature most difficult of good reproduction is the portrait which appears on the face of every note. The portraits of the famous Americans on United States paper money

identify the denominations of the bills on which they appear, as follows

\$1	Washington	100	Franklin
2	Jefferson	500	McKinley
5	Lincoln	1,000	Cleveland
10	Hamilton	5,000	Madison
20	Jackson	10,000	Chase
50	Grant		

The distinct and lifelike appearance of the genuine portraits is an effect achieved by artistically engraved dots and lines. The oval background around each portrait is made up of a series of tiny squares formed by the crossing of very fine vertical and horizontal lines. On the genuine bill the portrait and the background are clean and clear. On most counterfeits, the face-shading in the portrait is noticeably defective, and many of the little squares in the background are filled with ink or are flecked with white where the lines are broken. In the genuine portrait the eyes are always lifelike and expressive, but in most counterfeits they are dull, distorted or otherwise executed so that they are obviously inferior to the genuine.

Good money looks good.

Genuine engraved plate makes clear lines.

It is these differences between the genuine and counterfeit portraits which prompt the Secret Service advice to the money-handler to compare any questionable bill with another of the same type known to be genuine.

There are only three basic types of paper money issued by the United States: (1) silver certificates, (2) United States notes and (3) Federal Reserve notes. As a war measure, the Treasury Department in December 1942, released \$660,000,000 in National Currency notes, Series of 1929, but the government no longer prints currency of this type, and the issue is being retired as the notes wear out.

On the face of every genuine bill appears a small circle edged with sharp points like the teeth of a saw, enclosing an angle square under which is a key and over which is a balance scale, all mounted upon a dotted white shield within the circle. This is the Treasury seal, as indicated by the abbreviated Latin words surrounding the design, *Thesaur. Amer. Septent. Sigil.*, meaning *Thesauri Americae Septentrionalis Sigillum*, translated "Seal of the Treasury of North America." The color of the Treasury seal will quickly denote the type of bill on which it appears. On silver certificates the seal and the serial numbers are printed in blue; on United States notes they are in red, and on Federal Reserve notes in green. On the National Currency notes, Series of 1929, previously mentioned, the seal and serial numbers are brown. In addition, the type of note may be identified by the words "Silver Certificate,"

"United States Note," or "Federal Reserve Note," engraved at the top center of the face of a bill.

The counterfeiter usually finds it difficult to print a Treasury seal on which the points are as sharp and clear as they are on the genuine. On most counterfeits the points are dull or broken, and here again a comparison will reveal the counterfeit.

The serial numbers on genuine United States currency are printed in a distinctive type style, obtainable only by the Bureau of Engraving and Printing. The counterfeiter, therefore, must either use numbers unlike the genuine or must try to copy the genuine numerals. In the first instance, a comparison will show the difference in the style, and in the second instance the imitated numbers are generally spaced poorly or are aligned crookedly, and again a comparison will show that they are not authentic.

The border design of every genuine bill includes an intricate pattern of fine white lines in a fish-net motif. This pattern is produced

Bad money looks bad

Etched counterfeit plate makes broken lines.

by a complicated machine known as a geometric lathe, and the lines are called geometric lathe-work. In a genuine bill the lines are clear and unbroken. On most counterfeits, however, the border is too dark because many of the lines are obscured by black patches of ink due to inferior etching, or the white lines may be thicker than the genuine, thus creating a splotchy or a bleached effect.

It is a common belief that rubbing a bill on a piece of paper will prove whether it is genuine or counterfeit, through removal of the color. This is definitely a fallacy. The ink can be rubbed from a good bill as well as a bad one.

Counterfeit Coins.—The losses by victims of counterfeit coins are not as great as those resulting from acceptance of bogus bills, because there is a wide margin of difference between the value of metal money and the representative value of paper money. However, the passer of counterfeit coins depends upon the carelessness of his victims in the same way as does the passer of counterfeit bills. Potential victims of the coin passer can learn to detect spurious coins by a few simple observations and tests.

Genuine silver coins have a corrugated outer edge, known as the reeding. Consisting of evenly spaced ridges, the reeding was originated to prevent unscrupulous persons from cutting or filing from the edges of the coins small bits of silver or gold, which they would then sell for the value of the metal so accumulated.

Further reproduction, in whole or in part, is strictly prohibited.

Later, however, the reeded edges of silver coins formed considerable protection against counterfeiting, as they are difficult to reproduce perfectly. On most counterfeit coins the corrugations are only partially executed, or unevenly spaced, or entirely missing in places, and a comparison of a questionable silver coin with one known to be genuine, or even a careful inspection of the ridges around a questionable coin, will usually indicate whether it is good or bad.

Genuine silver coins, when dropped on a hard surface, produce a clear, bell-like ringing sound. Most counterfeit coins are made of metal alloy which is much softer than silver. Therefore, questionable silver coins should be dropped on a hard surface to test their ring, and should be cut with a knife to test their quality. If a coin sounds dull or is easily cut, it is undoubtedly a counterfeit.

Most counterfeit coins feel greasy, so it is wise to feel all coins, and if one feels slippery or greasy it should be examined further for defects in the reeding or other characteristics.

Bogus silver coins may be detected with a solution, the formula for which is as follows:

Nitrate of silver.....	10 grains
Nitric acid.....	1 cc.
Distilled water.....	30 cc.

The silver test may be obtained for a few cents in any drug store. A single drop applied to a counterfeit coin which does not have a high silver content will bubble and turn black instantly. The solution will not discolor a genuine silver coin and will not react on a counterfeit coin which is made of silver or which contains a high percentage of silver, but since most counterfeits are made of base metal the acid will detect them. It cannot be used to detect counterfeit pennies or nickels, or gold coins.

To the recipient of counterfeit money the Secret Service gives this advice:

- (1) Do NOT return it.
- (2) Notify police at once.
- (3) Try to delay the passer by making some natural excuse.
- (4) Avoid argument. If necessary, say the police will handle the matter.
- (5) If the passer leaves before police arrive, write down his description.
- (6) Write down the license number of any automobile used by the passer or his accomplices.

The federal laws for the protection of obligations of the United States provide that any person who has custody or control of counterfeits of such obligations and shall fail or refuse to surrender them to an authorized agent of the Treasury Department shall be fined not more than \$100 or imprisoned not more than one year, or both. All banking institutions are such authorized agents under an order issued by the Secretary of the Treasury 17 Oct. 1941, and amended 29 Jan. 1942, and are empowered to confiscate counterfeit money for surrender to the Secret Service.

Counterfeiting is a felony, and under the law any person who has knowledge of the commission of a felony recognized by the federal courts, and who does not at once make such knowledge known to the authorities, shall

be fined not more than \$500 or imprisoned not more than three years, or both. (Section 286, Title 18, United States Code of Laws.)

The manufacture or passing of counterfeit bills is punishable by a fine not to exceed \$5,000 and maximum imprisonment of 15 years. (Sections 264-265, Title 18, United States Code of Laws.)

Late in 1944 the United States Criminal Code was amended by an act making those who conspired to make counterfeit bills and other obligations liable to sentence of 15 years or a fine of \$5,000 or both, as in the case of offenders who actually produced such counterfeits. (Section 178a, U.S. Criminal Code, Section 293a, Title 18, U.S. Code.) Prior to enactment of this legislation, the penalty for conspiracy to counterfeit was imprisonment for not more than two years, or a maximum fine of \$10,000, or both. (Section 88, Title 18, U.S. Code.)

The making or passing of counterfeit gold or silver coins intended for the use and purpose of current money, whether in resemblance of coins of the United States or of foreign countries, or of original design, is punishable by a maximum fine of \$3,000, or imprisonment for not more than five years, or both. (Section 281, Title 18, United States Code of Laws.)

The making or passing of counterfeit minor coins is punishable by a maximum fine of \$1,000 and maximum imprisonment of five years, under Section 282, Title 18, United States Code of Laws. An amendment to this Section, designated Section 282-A, approved 1 April 1944, prohibits the unlawful use of tokens, slugs, disks, or other devices similar in size and shape to the coins of the United States, fixing a penalty of a fine not to exceed \$3,000 or imprisonment for not more than one year, or both.

FRANK J. WILSON,

Chief, United States Secret Service.

Consult: Crump, I., *Our United States Secret Service* (New York, 1942).

COUNTERMARK, in numismatics, the name given to those stamps or impressions which are found on ancient coins or medals, and have been given since their first impress. These countermarks or stamps are often executed without any care, and frequently obliterate the most interesting portion of the original inscription. There have been various opinions respecting the cause of these countermarks; some antiquaries thinking that they were to indicate an augmentation of the value of the money upon which they were stamped; others, that they were vouchers for workmen, and, again, that they were only struck upon money taken or received from foreign enemies. During the long war with revolutionary France Britain stamped millions of Spanish dollars with small, oval countermarks of the head of George III upon the neck of the Spanish monarch. Many of them were completely re-stamped or countermarked in the mint, but the new impression sometimes failed to obliterate the old entirely.

COUNTERPOINT, from the Latin, *punctus contra punctum* (note against note), the correlation of simultaneous melodic elements; also, a melodic element which is played against a pre-determined melody (*cantus firmus*). While the

term "melodic" does not exclude qualities of melodiousness or thematic salience, it pertains to broader considerations of linear continuity.

Counterpoint, polyphony, and homophony stand in an interesting relationship to each other. The first term usually refers to the precise nature, often the syntactic features, of combined parts. Polyphony refers to a type of music characterized by the simultaneous appearance of thematic or markedly melodic elements. Contrapuntal values are therefore a clearly recognizable factor in polyphonic music. But similar values are present in homophonic music, wherein a predominant melodic element is supported by an essentially chordal accompaniment. Because the bass, in particular in this style, is a separable linear element, regardless of the degree to which its contours might be a series of melodic stereotypes due to harmonic considerations, it forms continuous relationships with the principal melody. It is in such interdependence of moving parts that the essence of counterpoint lies.

In this sense counterpoint, as the source of homogeneous linear activity, is a factor common to many kinds of music, from the polyphonic *ricercare* to the simplest setting of a hymn tune. The musical analyst who points out the presence of passing or neighboring chords or tones, or suspensions, is thereby isolating rudimentary contrapuntal features. Indeed, many chords and chord progressions which are usually regarded as harmonic components of music are, in fact, contrapuntal derivatives. On a more abstract level contrapuntal as well as harmonic forces act as agencies of musical design, insofar as these forces give shape and direction to the details of musical texture. Thus, in the crucible of counterpoint, homophony turns out to be a congealed polyphony, and polyphony a liquefied harmony.

Counterpoint, often qualified by the terms "strict" or "species," and "free" is also a disciplinary study pursued by the student of music. In strict or species counterpoint certain laboratory restrictions are imposed by reducing to a minimum such accessory factors as harmonic logic, elements of motif, and particularized expressiveness, in order to emphasize and control the relationships generated solely by moving parts under stipulated conditions with regard to rhythm and the treatment of consonances and dissonances. Often this study is related to aspects of 16th century vocal polyphony and leads to the composing by the student of motet-like pieces. The study of free counterpoint is usually modeled after instrumental polyphonic practises of the Baroque era and in its turn leads to the composing of canons and fugues in the manner of the period. But the benefits of these studies lie less in the imitation of specific historical styles than in the inculcation in the student of elementary contrapuntal techniques which have an eventual validity for all styles. See also HARMONY.

WILLIAM J. MITCHELL,
Professor of Music, Columbia University.

COUNTERSIGN, in military affairs, a means of mutual identification in a combat area or, under special conditions, in garrison. It consists of two elements: a secret challenge given by a sentry after his initial routine challenge; and a secret response (the password)

of the person approaching, given only after hearing the proper secret challenge. The secret challenge and the password may consist of words or distinctive sounds. They are changed at irregular intervals, but often enough to maintain secrecy. Possession of the password does not in itself constitute a right to pass. The challenged person may be subjected to further scrutiny to establish his identity and authority. Unauthorized disclosure or use of the countersign in time of war is a capital offense under Article 101 of the Uniform Code of Military Justice. In some foreign armies the password alone is referred to as the countersign.

VINCENT J. ESPOSITO.

COUNTRY- or **CONTRE-DANCE**, the generic name for a whole series of figure dances of rural English origin; more specifically, the name given dances in which a number of couples stand at the beginning of the dance opposite each other, in two lines, an example being the *Sir Roger de Coverley*. Country-dances moved from the rural scene to aristocratic circles, and became popular with Queen Elizabeth I. John Playford's *English Dancing Master* (1650) is still the authority for both steps and tunes. It is probable that the country-dance was imported into France at the close of the 17th century and from there to Germany. *Contre-dance* is a corruption of country-dance.

COUNTY, a political and administrative subdivision through which important functions of government are performed in Great Britain, the British dominions, and the United States. At the time of the English settlements in North America the county in the mother country was the principal unit for the enforcement of law, the administration of justice, and representation in Parliament. It is not surprising therefore that counties were established in all the thirteen colonies and subsequently in the other states of the United States. The only exception, and that in name only, is that the unit of government in Louisiana corresponding to the county in other states is called the parish. Except for a number of independent cities, such as Baltimore, Md., St. Louis, Mo., and a group of Virginia cities, every part of each state has been included in some county. Several of the larger cities are coextensive with counties, Philadelphia, New Orleans, Denver, and San Francisco being important examples; and New York City contains five counties.

In Great Britain large boroughs usually are counties by themselves. From 1888, it became customary to advance a borough to the rank of county borough on its reaching 50,000 population, but in 1926 the population requirement was raised to 75,000, and in 1945 to 100,000.

There are in the United States approximately 3,000 counties. In New England they are of less importance than the township, and they achieve probably their greatest importance in the South and the Far West. The range in area of about two thirds of the counties is from 300 to 900 square miles. San Bernardino County, Calif., with 20,131 square miles, is the largest. Most counties were established as they now are before the invention of the automobile, and their size was roughly adjusted to public convenience in a time of horse-drawn vehicles and dirt roads. The variation in population is even more striking

than in area, extending all the way from a few hundred to three or four million. About half of all counties have less than 20,000 population, and the great majority are distinctly rural in character. Except in New England and in the other states in which there are organized towns or townships (New York, New Jersey, Pennsylvania, Ohio, Indiana, parts of Illinois, Wisconsin, Michigan and Iowa) the county is the only unit of rural local government. It is thus for many millions of Americans the only unit through which their desires for local self-government can be expressed.

The county is everywhere in the United States the primary unit of judicial administration, and the principal trial courts for both civil and criminal matters sit periodically in its courthouse. It is common to combine two or more counties in the organization of the circuit or superior court, but where this is done the judge sits alternately in each county, and each county has its own clerk, prosecuting attorney, sheriff, and jail. Except in some New England states, the recording of legal instruments such as deeds and mortgages and the probating of wills is on a county basis. The courthouse thus becomes the center of many of the most important contacts between the citizen and his government. Except, again, in New England, the county is the unit employed by the state in the conduct of its general elections, and, as a result, it is ordinarily the basic unit of party organization. This fact has an important bearing on the ill success of efforts to simplify local government in any manner which involves the elimination or combination of counties, or even the alteration of their boundaries.

Other functions of government commonly entrusted to counties outside New England are the building and maintenance of highways and bridges and the relief of the poor, including the conduct of almshouses and other institutions. The sheriff has important duties with regard to the enforcement of law and the preservation of peace, especially in rural sections, though there is nowadays an increasing tendency to entrust these matters to a professional state police force. The county frequently is the unit for public health activities. It is also the center of elaborate state and federal agricultural programs. In some states it is the unit of school administration and where schools are organized by smaller local units exerts some form of supervision of their activities. Incidental to its other functions the county provides for the assessment of property for tax purposes and for the collection of property taxes for those states which continue property levies, for the county, and frequently for cities, townships, and school districts. (For the manner in which counties are organized to perform their functions see **COUNTY GOVERNMENT IN THE UNITED STATES**.)

The pattern of county boundaries, which has not been subject to the slightest change for two generations, is today inadequate for counties containing large cities or forming parts of the extended metropolitan areas, and for the poorer rural sections of many states. In neither of these cases does it now correspond with the social and economic facts of the situation. County lines cut some metropolitan areas into fragments which prevent integrated solutions of metropolitan problems. Even where a single county contains all or most of the metropolitan area it cannot render the services required by the population pouring

out of the urban center except by costly duplication of what could be better done by the nucleus city. If, as it usually does, the county taxes property in the nucleus city and spends the proceeds in the suburbs, there is serious cause for dissatisfaction. On the other hand, in the poorer rural sections hundreds of counties have not the tax resources necessary to provide even primitive rural services to their people. This is particularly true as to roads, education, and welfare activities. These counties continue to function only by virtue of state subsidies which are proportionately much larger than in the cases of more populous and wealthier counties. In most states the work of county government could be done better and more economically by one third to one half the present counties. Even at two or three times their present size, counties would be easier to traverse than were existing counties fifty years ago. Obvious as these facts are, and though frequently called to the attention of the public, the number of consolidations since 1900 of counties with other counties or with cities has been very few.

COUNTY BOARD, the body which under a variety of names and with various forms of organization and powers serves as the governing body of all counties in the United States except those in Rhode Island. There are two main types of such boards, small boards of from three to seven members, and large boards of ten members or more. Board members are popularly elected in all states except Connecticut and South Carolina. The members of small boards, who may be chosen at large or by districts, are most frequently called county commissioners and are to be found in New England, Pennsylvania, Maryland, Ohio, Indiana (see **COUNTY COUNCIL**), part of Illinois, Nebraska, Kansas, Minnesota, the Dakotas, California, Oregon, Washington, Idaho, Montana, Wyoming and Nevada, besides several southern states. Boards of this type usually are contrasted by writers on local government with the large boards of supervisors found in New York, Michigan, Wisconsin, and most of Illinois. These latter boards are made up of township supervisors, who are the principal administrative officers of their townships, and of representatives elected from the cities within the county. Boards of supervisors in counties containing large cities are often of such great size as to be very unwieldy. It is entirely unsafe, however, to classify county boards in accordance with their names alone. There are small boards in Virginia, California, and Mississippi, which are known officially as boards of supervisors. In other states, like Missouri and Oregon, they are called county courts, while the small boards in most New Jersey counties are called boards of chosen freeholders. On the other hand, there are large boards in some southern states which are made up of locally elected justices of the peace and retain the name of court, while in Louisiana the governing body of the parish (county) is a large board elected by "wards" and known as the "police jury" (see **COUNTY GOVERNMENT IN THE UNITED STATES**).

The members of small county boards in large counties often receive substantial salaries and devote all or a considerable portion of their time to affairs of the county. Township supervisors, in addition to their regular salaries, receive some compensation for their services on the county

board. In the great majority of small counties, board members merely receive nominal salaries or none at all.

COUNTY COUNCIL, the name applied to the governing bodies of administrative counties in England and Wales under the Act of 1888 and subsequent legislation. In organization and methods of operation they correspond very closely to the borough councils of English urban communities. The most important of these councils is that of the administrative county of London, known as the London County Council, which exercises broad powers in the management of the largest municipality in the world. The English county councils manage the affairs of their counties through committees, one of which supervises the conduct of the professional head of each of the various departments.

In the United States the term "county council" was introduced in Indiana in 1892. At that time a county council of seven members, four elected by districts and three at large, was established in all Indiana counties, with the exclusive power of levying taxes, making appropriations, borrowing money, and buying and selling real estate. The old boards of county commissioners were retained in a purely administrative capacity (see **COUNTY GOVERNMENT IN THE UNITED STATES**, and **COUNTY BOARD**). The term county council has also been applied in a few cases to the governing bodies of counties reorganized under recent legislation.

COUNTY GOVERNMENT IN THE UNITED STATES. Much has been written on county government in the United States since 1917 when H. S. Gilbertson's *The County, the Dark Continent of American Politics* was published. Despite some improvement in certain features of county government and the advantages taken by a few counties of the county home rule provisions in force in some states to establish well-organized forms of government, the county remains today a jungle of confusion, disorganization, and irresponsibility. Exactly why the forces of reform, which have so vitally affected state government on the one hand and city government on the other, have passed the county by is difficult to explain. Perhaps the best general explanation is to be found in the amorphous character of county government and the close and important connection between this government and the great political parties of the country.

To assert that county government is amorphous is to say merely that the county, except in the case of a few recently reorganized ones, scarcely has a government at all in the same sense that cities do. The governmental activities carried on in the county are not integrated into even a faint approximation of a responsible county agency. County government therefore is not only much more difficult to describe than city government, but much more difficult for the citizen to comprehend and for public opinion to control.

County Government in New England.—The county is at its simplest in New England where it is little more than a judicial district of the state, other usual activities of local government being attended to mainly by the towns and cities. Aside from the judges, prosecuting attorneys, sheriffs, and clerks of court, there are no important county officers. Even the registration of deeds and other documents, a universal county

function outside of New England, is in Vermont, Connecticut, and Rhode Island, taken care of at the town level. In these states there is little for a county board to do except maintain the courthouse and jail. Rhode Island, indeed, manages without any county board at all. In the other New England states, except Connecticut, a board of county commissioners (in Vermont known as assistant judges of the county court) is elected by the people of the county, but in New Hampshire and Connecticut the levying of taxes and making of appropriations are left to a biennial convention of the members of the legislature from the county, while in Massachusetts estimates of the county commissioners must be passed upon by the legislature as a whole. The New England county, in other words, is almost wholly an agency of the state government and the element of local popular control has been reduced to lower terms than elsewhere in the country. The county in New England cannot be said to have much to do with local self-government.

The County as an Agency of the State.—

Having dealt with county government in the six New England states, it is possible to speak in reasonably general terms of county government in the remainder of the country, for while there are many variations in details, county governments elsewhere follow essentially the same disordered pattern. That pattern owes its principal characteristics to two factors. The first of these is the necessity of each state to have some reasonably uniform territorial organization to make its laws and policies effective throughout its borders. The county filled that need in 17th century England and it was natural that the colonists should have established a similar unit of administration in their new settlements. The county was from the beginning a comprehensive unit covering every settled part of each colony. In the colonies from Maryland south, except Virginia where in the early days the "parish" was an important unit of local policy, it was the only such unit. In the remainder of the colonies the county existed concurrently with a smaller unit, the town. It differed radically from units like cities, boroughs or villages, set up primarily to serve the special needs of their inhabitants, because its chief reason for existence was to serve the interests of the colony as a whole.

The early counties, like those of England prior to 1888, were set up primarily to provide for the enforcement of law and the administration of justice, although they performed other functions such as the care of the poor or the repair of roads and bridges by issuing court orders addressed to individuals or minor local units. For example, the law in the Massachusetts Bay Colony required each town to maintain a school, but it was the county court which enforced the law by citing before it and fining towns which balked at the performance of this duty. As the colonies became states and new states were added to the Union, counties spread over the whole country. A new officer, the prosecuting attorney, unknown to the English law, was added to the traditional sheriff, coroner, and clerk of court. As state activities expanded, administration in the modern sense became necessary and a whole additional crop of county offices was created. Lists of these positions differ only in detail from state to state. Since all through the 19th century both state and local governments depended for their support on the general property tax, a county assessor or

board of assessors was found necessary except in those states with organized township government, and even there a county officer or board was often set up to equalize assessments as between townships. To collect taxes, a county treasurer or tax collector was equally necessary. The frequency of real estate transfers in a new country made desirable a system of registration of all documents relating to the sale or mortgaging of lands and buildings. This function often became one of the duties of the county clerk, an office sometimes combined with that of the clerk of court. In some counties, however, there was a separate registrar of deeds. Another officer found in most counties was the surveyor whose function, now of little importance, was to make authentic surveys of lands in order to settle or head off boundary disputes which were very common in a new and rapidly growing country. With the development of public school systems the county became the actual unit of educational administration in only a small minority of the states but in states with district or township units there was usually set up a county superintendent and often a county board of education with very mild powers of supervision over district or township schools. All the above officials were primarily in the service of the state but with rare exceptions they were not made directly responsible to any state authority.

The second of the factors determining the character of county government was that during the same period in which county offices were being multiplied, prevalent American political theory leaned heavily in favor of popular election of public officials. In general, the whole list of officials, from circuit judge to county superintendent of schools, was made elective by the voters of the county or, in the case of the judge, by the people of the circuit. Such control as the state exercised over these public servants was by virtue of long and detailed statutory definitions of their powers and duties, a control in one sense more rigid than would have been exercised by an administrative superior in the state capital, but scarcely as effective. Owing their offices to the people of the county, these officials carried out their state-imposed activities in the way most satisfactory to their constituents. The general effect was a degree of decentralization fatal to the vigorous execution of the policies of the state. Not only were county officials not effectively tied to the state government, but they had no organization among themselves. Each was independent of the other, and any teamwork among them was due to the innate good feeling of the individuals concerned or to their common domination by a party machine or boss. The states in the formative period did not set up any general organ of county government other than the county board (see COUNTY BOARD). There were such boards in all states outside of New England. They generally were elected by the people of the county and had nominally the power of the purse, that is, they made appropriations and levied taxes for the support of the county government. In fact, however, the amounts of many expenditures were mandatory under state law. Further, it was common practice until well into the 20th century for many of the principal county officers—sheriff, clerk, tax collector, etc.—to be paid by fees which they collected, in turn paying their deputies or assistants and other expenses of their offices and retaining the balance for themselves, thus making

them entirely independent of the county boards. This condition still continues in several of the states. Where it does not survive, the law often so minutely specifies the salaries of county officers and the number and compensation of their staffs as to leave the county commissioners or board of supervisors, as the case might be, powerless to control them. The abolition of the fee system, while beneficial in many ways, has scarcely at all enhanced the authority of the county board.

The developments of the first fifty years of the 20th century have had on the whole very little effect on this situation. The principal traditional county offices are frequently so embedded in the constitutions of the states as to block all attempts to bring them into any scheme of responsible county government. There are isolated cases of reform, such as the appointment of the sheriffs in the five counties of New York City by the mayor. Sheriffs in some counties have been bypassed as law enforcement officers by the creation of county police forces under the control of the county board. The merit system has been extended to county positions in a few instances, but by and large, county appointive offices are still treated as political spoils. Accounting procedures have been improved and in some cases a county auditor or other fiscal officer has been introduced, with some powers of control over the receipts and expenditures of even the elective officials. The improvements which have been made in county organization, however, relate as a rule only to the activities under the control of the county board. Even in those counties which have adopted the county manager plan the relation of the county board to the traditional county officers has scarcely been altered.

The County as a Unit of Local Self-Government.—As previously stated, the county has from the beginning had some powers of local self-government. These powers have gradually increased in importance, especially in the populous counties adjacent to or including large cities. Counties, historically speaking, were not municipal corporations and had only those powers specifically conferred on them by the legislature. In some states their powers are still much restricted. However, in others—Virginia for example—they have been given power to do practically anything which a city can do in such fields as planning, zoning, building regulation, and many varieties of public works. Many counties today spend large sums of money in the performance of functions which at the turn of the century would have been regarded as peculiarly municipal. While county functions for the most part are still confined largely to the construction and maintenance of courthouses, jails, roads and bridges, and to provisions for health, welfare (that is, the various forms of relief), and, in some states, schools, the sums of money to be spent on these objects have increased so much as to greatly enhance the importance of what may be called the discretionary powers of county government.

Such discretionary functions as were exercised in English counties at the time of the settlement of the thirteen colonies were vested in the Court of Quarter Sessions, consisting of justices of the peace appointed by the crown from among the landed gentry. In the colonies the control of county affairs likewise originally belonged to the courts. Early in the independent history of the United States, however, these were generally replaced by elective county boards, thus giving the

county a genuinely representative governing body for the limited functions within their jurisdiction. It cannot be said, however, that county boards as a rule have distinguished themselves in the exercise of these self-governing powers, especially when the functions concerned have reached considerable proportions. A number of factors have contributed to this result. Counties were slow to recognize the necessity of professional assistance in the performance of their duties. In those states in which the county board is chosen by districts, the care of roads and bridges in each district was originally left to the member from that district. This worked fairly well when road building could be carried on by any group of farmers with the assistance of primitive plows and scrapers. Even today in many wealthy counties which employ engineers to design their roads, the spending of money on construction and maintenance of roads and the selection of the men to be employed on them are left to the members from respective districts. Where the county board is elected at large, a similar result is obtained by dividing the board into committees on courthouse, roads, county home, and the like, each committee tending to become an independent agency with which other members of the board do not interfere.

There has been little to choose between the large boards of New York and of the states which have copied her "town supervisor" system, on the one hand, and the three-member boards of Pennsylvania and Ohio. Probably the basic reason for the failure of all types of boards to evolve a first-rate system of county administration lies in the fact that except in strictly rural counties county government in general is too far removed from the effective control of public opinion. Counties in which there are cities of any considerable size usually render little or no service within the city limits except the maintenance of the courthouse and the courts and judicial offices located there. The people of the city take little interest in the county government and are frequently hopelessly under-represented in it. On the other hand, the high assessed valuations in the city provide at moderate rates of taxation most of the money lavished on the remainder of the county. City voters have a tendency to write off county government as a bad job and either do not vote in county elections or simply support the party to which they belong. The county people are satisfied with what they are getting and the county political machine runs on smoothly without danger of upset. Of course, there are counties in which this situation is reversed but they are decidedly the exception.

It is not surprising under these circumstances that the movement for reform in county government has proceeded very slowly. California in 1914 adopted an amendment to her constitution authorizing counties to amend their charters by electing boards of freeholders in a manner similar to that previously provided for cities. Since that time six other states have given their counties a like privilege: Maryland (1915), Ohio and Texas (1933), New York (1935), Washington (1938), and Missouri (1945). Several states also have constitutionally authorized optional acts permitting the adoption of the county manager and other plans of county government: Montana (1922), Virginia (1928), New York (1935), Oregon (1944), and Louisiana (1945). Optional acts have been put on the statute books in these

and other states: Georgia (1922), North Carolina (1927), Montana (1931), Virginia (1932 and 1938), New York (1935, 1936, and 1937), North Dakota (1941). The "home rule" provisions in the Ohio, Texas, Washington, and Missouri constitutions have produced no county home rule charters. Louisiana has as yet no optional charter act to implement its constitutional provision. The number of counties which have taken advantage of either the home-rule or optional act privileges offered them is extremely limited, although it includes some very large and important counties.

In California five of the principal counties of the state—Sacramento, San Mateo, Santa Clara, Los Angeles, and San Diego—have adopted home rule charters. The first three of these are classed as county manager charters by the National Municipal League in its *Digest of County Manager Charters and Laws*, a loose-leaf publication supplemented from time to time as new charters or laws are adopted. It is to be noted that in Sacramento and San Diego counties the assessor, district attorney, auditor or controller, and sheriff, continue to be elected by the people, as well as the judges. In Santa Clara County the list of elective officers is the same except that the auditor or controller is appointed by the manager, while the superintendent of schools is elected by the people. These are all fair examples of the manager plan as applied to counties and have been in successful operation since the early 1930's.

Los Angeles and San Diego counties require special mention because their charters, adopted in 1938 and 1947 respectively, provide for a distinctive form of administrative organization which in some quarters is regarded as an acceptable substitute for the manager plan in either city or county government. Unlike the manager plan, in which the power of appointment to the most vital positions in the administration is vested in the manager, this power is retained by the board of supervisors. The board appoints in each case, however, a chief administrative officer who serves as the connecting link between the board and the army of employees of these great counties. He has no power other than what he derives from the support of the board of supervisors. In Los Angeles County, now the most populous county in the United States, the relationship between the chief administrator and the board has been one of harmony and confidence, with correspondingly successful results. This probably has been due to the personalities involved rather than to the overall merit of the system. Experience in San Diego County has been too short to warrant drawing valid conclusions.

Three of New York's largest counties outside New York City—Westchester, Nassau and Monroe (Rochester)—now operate under charters which provide for effective executive control and modern budgeting and accounting practices. In Monroe County, administrative authority is vested in a county manager appointed by the board of supervisors. In Nassau and Westchester counties there is an elective executive, whose powers are substantially the same as those of a manager. Monroe County has retained the large board of 43 supervisors, elected one from each of 24 city wards and 19 towns. The Westchester board is even larger. Both boards exceed in size the upper chambers of many state legislatures. Nassau County, which contains but three towns and two cities, has a board of five supervisors.

Two additional county manager charters, those

of Anne Arundel and Montgomery counties in Maryland, adopted in 1949, complete the crop of modern charters springing from home rule charter provisions in state constitutions. The use of optional acts, where provided for, likewise has been by no means extensive. The Virginia law has been used four times, the North Carolina law twice, and the Montana law once to adopt the manager plan. By far the most liberal of the optional acts are the three operative in New York which offer to all counties outside New York City, 16 forms of government, with opportunity for numerous minor variations in each. The very variety of these options, however, results in their use for piecemeal amendment of the existing system of government rather than for wholesale reorganization.

A few other county governments have also been reorganized by special acts, the most important of which provided the manager charter of Fulton County (Atlanta), Georgia, which, however, does not attempt to bring the traditional constitutional officers under the authority of the manager. Altogether there were in June 1950 15 county manager governments of approximately standard pattern in the United States and perhaps twice that number of counties in which some kind of elective or appointive county executive existed. The remainder of the counties in this country still had the traditional formless type of government described in the early sections of this article.

The actual operation of counties as units of local self-government has been more deeply affected by certain economic developments of recent years than by conscious efforts at reform. The importance and costliness of the highways required by the automotive age have brought about in several states the absorption by counties of the highway activities of the townships, leaving the latter units little excuse for existence. On the other hand, more and more former county roads have been included in state highway systems administered directly by state highway departments. In North Carolina, responsibility for the construction and maintenance of all roads has been assumed by the state. In 98 of the 100 counties of Virginia, the state highway department takes care of all roads, both primary and secondary. It has been the experience of Virginia that as counties cease to have roads to look after, the county engineer is likely to disappear from the list of county offices and the county gradually stops performing any activities involving engineering skill.

When the United States government, in the Social Security Act, undertook old-age assistance and provided for aid to the blind and to dependent children, the county, in a majority of the states, became the unit through which a vastly increased volume of relief funds were to be expended. At the same time, however, the conditions on which federal aid was forthcoming required that the county agencies which actually administered relief should be organized on a uniform pattern; that the heads of these agencies should be persons approved by the state department of welfare in accordance with standards prescribed by the federal authorities; and that other personnel should be appointed from eligible lists based on examinations set up by the state departments of welfare. The county welfare agencies thus came to present, from the point of view of the professional character of their staffs,

a marked contrast to the other offices and departments of most county governments.

Education is technically and legally regarded as a state function, but the basic units through which education is provided often present the best examples of local self-government in the United States. In the great majority of states this basic unit is a district smaller than the county, and the county board of education or county superintendent of schools, one or both of whom are found in most of these states, act in a supervisory capacity. There are, however, 11 states in which the county, except where embracing large cities, is the actual unit of educational administration. These states are Alabama, Florida, Georgia, Kentucky, Louisiana, Maryland, North Carolina, Tennessee, Utah, Virginia, and West Virginia. In six of these states a board of education is elected by the people. In Georgia the board is appointed by the grand jury but the superintendent is elected by the people. In Tennessee, school boards are elected by the people in some counties and appointed by the county court in others. In Virginia they are appointed by an electoral board which in turn is appointed by the judges of the circuit court. In only two states—North Carolina, where they are appointed by the legislature, and Maryland, where they are appointed by the governor—is there any approach to state centralization of authority. These boards vary from 3 to 19 members, with 5 the most frequent number. In seven of this group of states the county board appoints the superintendent. In Alabama some superintendents are elected and some appointed by the county board of education. In Tennessee some are elected by the people and some appointed by the county court. Only in Florida and Georgia is popular election the general rule. The number of states with county-wide units for furnishing education to the people has been slowly increasing but as yet has not penetrated north of Maryland. County government today provides more services for vastly more people than ever before in its history. Unless present trends are reversed it is destined to occupy a constantly increasing place in the lives not only of rural but of many densely populated urban communities. The genuine reorganization of county government will be a major problem of American democracy in the second half of the 20th century.

THOMAS HARRISON REED,
Municipal Consultant, Wellesfield, Conn.

COUNTY SEAT, the name given in the United States to the locality in which the county courthouse and other county offices are situated. It is still possible, in some parts of the old South, to find county courthouses in the open country apart from any center of population, but this is very rare. If there were no inhabitants in the immediate vicinity when the courthouse was built, its presence usually attracted them. In the period of continental settlement there often was great rivalry among budding metropolises as to which should have the advantage of being the seat of the county government. As a result many state constitutions forbid the establishment or removal of a county seat except after a popular referendum. The resistance of businessmen and other inhabitants of county seats, as well as that of county politicians and office holders, has been an important factor in preventing the consolidation of counties.

COUP D'ETAT, cōō dātā', in politics, a sudden and decisive stroke of policy, usually unconstitutional and often accompanied by violence, by which the existing terms of government are drastically altered. The phrase is French in origin, meaning literally "stroke or blow of state." Although lacking in exact definition, it generally implies the extension of governmental authority by the ruling power through the use of arbitrary and coercive means, as distinguished from the revolutionary overthrow of a government by civil war or insurrection. There were at least three events in France commonly so characterized. The "18 Fructidor" (the French Revolutionary calendar term for September 4) was a "bloodless revolution" in 1797, creating little widespread interest among the people, in which the republican party defeated the party of reaction. The "18 Brumaire" (November 9, 1799) was another "bloodless revolution," executed by Napoleon Bonaparte and making him practically the ruler of France. On December 2, 1851, Louis Napoleon, who was then president, dissolved the assembly by a coup d'état. By skillfully manipulated and controlled plebiscites, he then persuaded the French people to extend his term as president to ten years (the constitutional limit having been four years) and in 1852 to make him emperor.

COUPE, kōō-pā', a four-wheeled carriage carrying two persons inside, with a seat for the driver outside; also, a type of continental stage-coach or a half compartment in British railway cars. The word coupé is best known in America when applied to a type of two-door automobile body seating two to five persons.

COUPER, kōō-pēr, William, American sculptor: b. Norfolk, Va., Sept. 20, 1853; d. Easton, Md., June 23, 1942. After studying at the Cooper Institute, N. Y., he went to Munich, Germany (1874), where he studied at the Royal Academy, and then to Florence, Italy (1875), where he entered the studio of Thomas Ball, whose daughter he married (1878). Returning to America in 1897, he established himself in New York City and became well known for his ideal works, portrait statues, busts, and bas-reliefs, among which were a statue of Henry Wadsworth Longfellow and busts of President McKinley and Robert E. Peary.

COUPERIN, kōō-prān, François (surnamed LE GRAND), French composer and clavecinist: b. Paris, Nov. 10, 1668; d. there, Sept. 12, 1733. The most distinguished member of a prominent musical family (see COUPERIN FAMILY), Couperin studied with his father and later with Jacques Thomelin, whom he succeeded as organist of the royal chapel in 1693. Established as organist at the Church of St. Gervais since 1685, he was appointed clavecinist and organist to the king in 1701 and *Ordinaire de la musique* in 1717. He was highly esteemed by Louis XIV, whose family he instructed in music and for whom he composed his *Concerts Royaux* (1714-1715; published 1722). Besides court compositions, he wrote many sacred works, including two organ masses, long attributed to his uncle, Sieur de Crouilly; but his fame rests chiefly on his *Pièces de clavecin*, programmatic dance suites, of which he published four volumes (1713, 1716, 1722, and 1730). Couperin also published four trio sonatas, entitled *Les Nations* (1726), and a group of ensemble

pieces, *Les goûts réunis* (1724), which, with *Le Parnasse, ou l'apothéose de Corelli* (1725) and *Apothéose de Lully* (1725), brought together the prevailing French and Italian styles. Couperin's music is noted for its individual ornamentation (interpreted in his *L'Art de toucher de clavecin*, 1716) and its intricate rhythms and counterpoint. The influence of his keyboard works is apparent in works of his younger contemporary, Johann Sebastian Bach.

Consult Couperin's works published by Cauchie, Maurice, and others, 12 vols. (Paris 1932-33); also Mellers, Wilfrid, *François Couperin and the French Classical Tradition* (London 1950).

COUPERIN FAMILY, a family of French musicians, who flourished in Paris as masters of the keyboard for nearly two centuries. Members of the family served as organists at the Church of St. Gervais, Paris, successively from the middle of the 17th century to 1826, except for the six-year tenure of Michel de La Lande (1677-1685). The first to become prominent in his profession was LOUIS COUPERIN (b. Chaumes, about 1626; d. Paris, Aug. 29, 1661), the eldest son of Charles Couperin, a merchant and organist in Chaumes, Department of Brie (now part of Seine en Marne). A student of Jacques Chambonnières, whom he accompanied to Paris, Louis was appointed organist at St. Gervais around 1650 and in 1656 became a court violinist and a musician in the *Chambre du roi*. His compositions include *Pièces de clavecin*, which contained some of the earliest examples of the *basso continuo* style in French harpsichord music.

The Couperin line was carried on by Louis' two brothers, François and Charles. CHARLES COUPERIN (b. Chaumes, April 7, 1638; d. Paris, 1679), the youngest of the brothers, succeeded Louis as organist of St. Gervais. He was the father of François, the most renowned of all the Couperins (see COUPERIN, FRANÇOIS), whose two daughters, MARIE-MADELAINE (b. Paris, March 11, 1690; d. Abbaye de Maubuisson, April 16, 1742) and MARGUERITE-ANTOINETTE (b. Paris, Sept. 19, 1705; d. 1778), were celebrated musicians, the latter substituting for her father as clavecinist to the king from 1731 to 1733.

Louis' older brother, FRANÇOIS COUPERIN (b. Chaumes, about 1631; d. Paris, 1701 or 1703), was called SEUR DE CROUILLY. Also a pupil of Chambonnières, he was active as an organist and teacher. He was the father of MARGUERITE-LOUISE (b. Paris, 1676 or 1679; d. Versailles, May 30, 1728), a singer, harpsichordist, and member of the *Chambre du roi*; and NICOLAS (b. Paris, Dec. 20, 1680; d. there, July 25, 1748), the successor of his famous cousin, François le Grand, to the post at St. Gervais (1733).

ARMAND-LOUIS COUPERIN (b. Paris, Feb. 25, 1725; d. there, Feb. 2, 1789), the son of Nicolas, was a well-known organ virtuoso, who succeeded his father at St. Gervais in 1748. He was organist to the king from 1770 to 1789 and held other appointments in several Parisian churches. He wrote much church and chamber music. His wife, ELISABETH-ANTOINETTE BLANCHET (b. 1729) was also a prominent organist and harpsichordist.

PIERRE-LOUIS COUPERIN (b. Paris, March 14, 1755; d. there, Oct. 10, 1789), the son of Armand-Louis, was also known as COUPERIN L'AÎNÉ or COUPERIN FILS. He was organist to the king and succeeded his father at St. Gervais eight months before his death. His compositions are found in manuscript and in published collections.

GERVAIS-FRANÇOIS COUPERIN (b. Paris, May 22, 1759; d. there, July 1826), younger brother of Pierre-Louis, succeeded him at St. Gervais in 1789 and was the last of the Couperins to hold that position, although his daughter, CELESTE (b. about 1793; d. Belleville, near Paris, Feb. 14, 1860), who taught singing and pianoforte, played there at the time of his death.

COUPERUS, kōō-pā'rūs, **Louis**, Dutch novelist: b. The Hague, Netherlands, June 10, 1863; d. De Steeg, near Arnhem, July 16, 1923. Of Dutch-Scottish ancestry, he spent his early years in Java, and thereafter traveled extensively throughout his life. After a few ventures in poetry, he published *Eline Vere* (1889), the first of his numerous novels delineating overrefinement and decadence in contemporary life, of which *De boeken der kleine zielen* (4 vols. 1901-1904) is outstanding. He also wrote historical novels, among which were *Dionyzos* (1904), *Antiek toerisme* (1911), and *Xerxes* (1919); short stories; and travel sketches. Many of his works were translated into English.

COUPLET, kŭp'lēt, in poetry, a pair of lines generally of the same length and cadence and rhyming with each other; formerly also known as a distich. A couplet may be part of the structure and thought of a stanza of more verses, or may stand as a separate metrical entity. An example of the first is the couplet which brings the English, or Shakespearean, sonnet to its forceful close. The independent couplet, often called the heroic couplet from its use in the heroic poetry of the 17th century, dates back to Geoffrey Chaucer (1340?-1400) and consists of a pair of rhymed 10-syllable verses (iambic pentameter). Alexander Pope (1688-1744) is generally held to have brought the heroic couplet to perfection. In his hands, the couplet attained a new suppleness often rising to epigrammatic power, as in the famous one from his *Essay on Man*:

Know then thyself, presume not God to scan;
The proper study of mankind is man.

COUPLING, kŭp'ling, in mechanics any device that connects the ends of two adjacent parts, such as two ends of a belt, shaft, or pipe. Shaft couplings may be the flexible type, to allow for misalignment, or the flanged face type, which permits no misalignment. Hooke's universal joint is a type of coupling adapted for transmitting torque between shafts fixed at an angle. Couplings are also used on railway cars (see RAILWAY CARS. PASSENGER AND FREIGHT) and in electric circuits (see RADIO—NATURE OF RADIO COMMUNICATION. —Coupled Circuits).

COUPON. See BANKS AND FINANCE—*Glossary of Terms*.

COURBET, kōōr-bā', **Gustave**, French painter: b. Ornans, June 10, 1819; died near Vevey, Switzerland, Dec. 31, 1877. Destined for the law, Courbet with all his native vigor and independence determined as a very young man that he would become a painter. He studied in Paris with Steuben and Hesse, but soon left his teachers to work by himself. He never joined forces with his impressionist contemporaries against their common enemy, conservatism. Like Manet he did not scorn the Salon, but constantly sent pictures in the hope that they would be ac-

cepted. In 1844 he exhibited there for the first time. Though his works were often rejected by the Salon, he won a medal in 1849, and the next year showed six pictures which occasioned tremendous discussion, among them his most famous work, the *Burial at Ornans*, now in the Louvre in Paris. This sombre and movingly faithful representation of a country interment, with mourners and vested clergy standing about an open grave, shocked the Parisian public because it made no concessions to convention and was an unaccustomed but accurate statement of a painter's fearless observation.

His frequent rebuffs by the Salon led Courbet to exhibit his works in Besançon and to take them to Germany where they and he were much admired. Twice in Paris he staged a one-man show at his own expense. His revolutionary tendencies were not confined to his art; he crusaded for democracy, was openly anticlerical, and in 1870, when director of fine arts, declared the Vendôme column a worthless monument. Under the Commune (1871), he removed it, an act for which he served a six-months prison sentence. Later, faced with the cost of re-erecting it, he fled to Switzerland, where he died.

Courbet himself labeled his work realism and this new dedication to rendering the truth of nature poured life into the moribund academic tradition, making possible the great French flowering of the second half of the 19th century. His portraits are strong, his landscapes and marines stirring, and his extraordinarily life-like paintings of the female nude exerted a great influence on later painters. Courbet's pictures may be seen in many museums in France and elsewhere in Europe and some of his finest are in America.

Consult for biography and criticism Silvestre, Théophile, *Histoire des Artistes vivants* (Paris 1856); Zola, Émile, *Mes Haines* (Paris 1866); Mantz, Paul, "G. Courbet" in *Gazette des Beaux Arts*, (Paris 1878); Estignard, A., *Courbet, sa vie et ses œuvres* (Besançon 1897); Riat, George, *Gustave Courbet* (Paris 1906); Leger, Charles, *Courbet* (Paris 1926); Mack, Gerstle, *Gustave Courbet* (New York 1951).

MARGARETTA SALINGER.

COURBEVOIE, kōōr-bē-vwā', city, France, in the Department of Seine, on the left bank of the Seine River, in the northwest suburbs of Paris. The city has a large electrical industry and manufactures automobiles, bicycles, plumbing supplies, soap, and cosmetics. In 1883 a bronze group, the *Monument de la défense de Paris*, by Louis Ernest Barrias, was erected here. Courbevoie suffered heavy damage during World War II. Pop. (1946) 54,025.

COURCELLE, kōōr-sēl', **SIEUR DE** (DANIEL DE RÉMY), French governor of Canada: b. Artois, France, 1626; d. Toulon, Oct. 24, 1698. A soldier who had served as governor of Thionville, Courcelle in 1665 was appointed governor of New France, which position he held until 1672. In 1666 he led an expedition against the Mohawk Indians who had been annoying the colony by constant attacks. He was forced to retreat because of the severe weather. Later his forces completely subdued the Mohawks, and in 1668 he concluded peace with the Iroquois. Several years later another war was averted when he ordered the execution of three French soldiers who had murdered an Indian chief. He left Canada in 1672 because of poor health, and returned to Paris. Appointed commander of Toulon, he retained that post until his death.

COURCELLES, Etienne de, French Arminian theologian: b. Geneva, 1586; d. Amsterdam, 1659. The son of a French Protestant refugee in Geneva, he was honored as a boy with the friendship of the celebrated Calvinist theologian and church historian, Théodore de Bèze. However, he adopted the Arminian doctrine concerning predestination. His tergiversations caused him to be suspected by both Protestant parties.

COURCELLES, kōōr-sēl', town, Belgium, in Hainaut Province, five miles north-northwest of Charleroi. Its chief industries are the manufacture of glass and iron, and coal mining. Pop. (1947) 16,287.

COUREURS DE BOIS, kōō-rūr dē bwā, or rangers of the woods. During the French regime in Canada, many adventurous Canadian youths, and even soldiers of the regular garrisons, subjected to the vexatious restrictions of a paternal government, took to the woods and lived the free life of the Indians, trading with and frequently marrying among them. This drain on the resources of the colony called for the strongest inhibitions from the representatives of church and state, and amnesties were offered to *couriers de bois* to return and engage in agriculture, but few availed themselves of these offers. They were, however, always loyal to the French interest, and their alliances with the Indians gave them great ascendancy over the savages and kept them friendly to the French power.

COURIER, kōō-ryā', Paul Louis, French writer and pamphleteer: b. Paris, Jan. 4, 1772; d. near Vézetz, April 10, 1825. Educated in military science by the wish of his father, Courier served (1793–1809) in several campaigns of the French Revolution. His chief interest, however, lay in classical studies. In 1810 he published an edition of Longus' *Daphnis and Chloe* (q.v.), taken from a Florentine manuscript, a portion of which had never before been translated. After the Restoration of the monarchy in 1814, Courier began writing a series of political pamphlets opposing the Bourbon government. For his satirical *Simple Discours* he was fined and temporarily imprisoned in 1821. The best of his works in this form was *Pamphlet des pamphlets* (1824), which appeared shortly before he was assassinated by one of his servants near his estate at Vézetz.

His *Oeuvres complètes*, with an essay on his life, were published by Armand Carrel (Paris 1830).

COURIER, kōōr'i-ēr (old French, *courier*, a runner), a bearer of special dispatches, whether public or private (see POST AND POSTAL SERVICE). The term also refers to a guide or attendant for travelers. His function is to facilitate travel by arranging all matters pertaining to passports, luggage, hotel reservations, and money exchange.

COURLAND. See KURLAND.

COURNOT, kōōr-nō', Antoine Augustin, French mathematician, philosopher, and economist: b. Gray, Haut Saône, France, Aug. 28, 1801; d. Paris, March 30, 1877. After teaching at the Academy of Paris (1831–1834) and at Lyons (1834), he made his profession as an educational administrator, serving as rector (1835) and then inspector general (1838) at the Academy of Grenoble and as rector of the Academy of Dijon

(1854–1862). Cournot's principal work, however, was in the field of mathematical probability applied to economic theory. Although he was not the first to use the methods of mathematics in this field, he is considered the founder of mathematical economics and the first to apply the apparatus of supply and demand functions to economic analysis. His most important economic treatise, *Recherches sur les principes mathématiques de la théorie des richesses* (1838), contained the earliest formulation of the modern theory of monopoly and dealt with such economic concepts as duopoly and perfect competition. This work is still highly regarded by students of economic theories.

Cournot's studies in the theory of chance led him to stress the importance of probability calculus for statistics, as well as to outline a philosophy of history in which chance plays a more consequential part than cause. He saw in the advance of civilization the gradual ascendancy of the calculable over the spontaneous and the order of mathematical combinations over the disorder of human life. His writings include *Exposition de la théorie des chances et des probabilités* (1843); *Essai sur les fondements des nos connaissances et sur les caractères de la critique philosophique*, 2 vols. (1851); *Traité de l'enchaînement des idées fondamentales dans les sciences et dans l'histoire*, 2 vols. (1861); *Principes de la théorie des richesses* (1863); *Considérations sur la marche des idées et des événements dans les temps modernes*, 2 vols. (1872); *Matérialisme, vitalisme, rationalisme* (1875); *Revue sommaire des doctrines économiques* (1877).

COURSER, kōr'sēr, one of nine species of birds, so called because of the speed with which they "course" or run over the open steppes and deserts, which are their preferred home. Together with the pratincole (q.v.) they comprise the family Glareolidae, allied to the plovers. They are found in the tropics of the Old World, especially Africa. Coursers are about a foot in length; their sandy or brown plumage matches the desert sands, but they often have conspicuous black bands across the chest. The famed crocodile-bird of the Nile is a somewhat aberrant member of this group.

COURSING, kōr'sīng, the pursuit of running game, such as deer, fox, or rabbit, by dogs, who follow their prey by sight instead of by scent. Coursing was practiced in antiquity and for many centuries was a means of providing meat as well as a popular sport in England, where rules for the judging of greyhounds were first established in the 16th century. By the 19th century, coursing was confined to the pursuit of the hare and had been introduced into America. It still is a popular sport in England, and competition for the Waterloo Cup (begun in 1836) is held annually at Altcar, near Liverpool. In the United States, however, public opinion ruled against the killing of rabbits for the sake of sport, and, in 1919, the invention of the mechanical rabbit inaugurated modern dog-racing methods.

COURT, kōōr, Antoine, French Protestant clergyman: b. Villeneuve-de-Berg, Ardèche, France, May 17, 1696; d. Lausanne, Switzerland, June 13 or 15, 1760. He was one of the most prominent Protestant leaders of his time and is commonly regarded as the restorer of the Reformed Church in France and the founder of

the "Church of the Desert." At the age of 17 he began to address secret assemblies of persecuted Calvinists. Impressed by the fact that the only way to maintain the religion was by organization rather than by the inspiration of zealots, he devoted his life to the building up of regular churches in the various small communities. To this end he summoned a synod of all the preachers in the Cevennes and lower Languedoc at Monoblet. A regular church system and rules were agreed upon. Pierre Corteiz received ordination at Zürich, and by him Court was likewise ordained. Persecutions broke out again in 1724, and Court fled to Lausanne (1730). There he labored incessantly for the founding of a college, of which he was the director and chief pillar for the rest of his life. From this college emanated the pastors of the Reformed Church of France. Court collected documents for a study of Protestantism in France, but his work was not completed and the materials are still preserved at Geneva. His best work is the *Histoire des troubles des Cevennes ou de la guerre des Camisards* (1760; new ed. 1819).

His son, ANTOINE COURT DE GEBELIN (q.v.) who took the name of his grandmother, was a French scholar of note.

COURT, Judicial. In its primary meaning the classical Latin *cohors* (*cors*), whence we derive the term *court*, signified an uncovered space enclosed within a residential curtilage. In the western European languages the derivatives of *cohors* eventually were applied generally to the official residence of a ruler and finally were expanded to include the ruler and the members of his official household, in whom the functions of government—legislative, executive, judicial—were centered. The English word *court* thus came to be used in the sense of a general governing body, such as the High Court of Parliament or the General Court of Massachusetts, the latter consisting of the governor and his council and both branches of the legislature, or as the official designation of a legislature, such as the General Court of Connecticut. Gradually, however, as the judicial function was separated from the others, the term *court*—at least among peoples of the Anglo-American legal tradition—became restricted with increasing exclusion to the institutions entrusted with its exercise.

Sir William Blackstone (1723–1780), the English jurist, defined a court as "a place where justice is judicially administered." Aside from its tautology, the definition is hardly adequate. In the Anglo-American conception a court is more than a place or an individual or a group of individuals. A court, in this view, is rather a functioning organization composed of individuals charged with duties defined by law and assembled at a time and a place fixed by law for the administration of justice.

The means employed by different societies to achieve justice between man and man are among the oldest of social institutions. Sir Henry J. S. Maine (1822–1888) has shown how among primitive peoples judicial awards were made by kings, priests, and rulers, long before custom had developed or legislation had been enacted, and how these awards were assumed to be the result of direct inspiration.

The means for achieving justice vary with the fundamental tenets of the societies in which they appear and with the stages of development which

they have reached. The judicial institutions of democratic differ from those of autocratic, monarchical, or theocratic societies. So also the judicial institutions of secular systems of law, such as the ancient Greek and Roman, and the present Anglican, American, and Chinese, differ from those of systems conceived as divinely revealed. Among the latter are the ancient Egyptian, Mesopotamian, and Hebrew systems, now extinct, and the ancient Hindu and the medieval Mohammedan systems, still in force.

Egyptian.—The first code of which we have any record is that of the Egyptians. By the time of the 4th dynasty (c.2900 B.C.), the king was established as royal theocrat, sole legislator, and judge. He was regarded as having derived from the sun-god Osiris his authority and the law which he administered. He delegated a large part of his judicial power to a chief judge, who by reason of that designation served as prime minister. Under him administrative officials acted as local judges.

Diodorus Siculus describes (*Bibliotheca Historica*, I, 75–76) the native courts as he observed them during the last days of the kingdom before Egypt became a Roman province (30 B.C.). The Egyptians were very solicitous for the character of their courts; only men of the highest standing from the principal cities were chosen as judges. The parties presented their claims and defenses in writing and witnesses were heard. No lawyers were permitted and there was no oratory.

The system continued under the rule of the Greek Ptolemies (323–30 B.C.) until the Roman conquest, when native judges were displaced by Roman officials who applied Roman law but conducted their proceedings in Greek. Seven centuries later came the Arabs, who subjected the Egyptian courts to the religious law of Islam (642 A.D.).

Mesopotamian.—Also conceived as of divine origin was the Code of Babylon. The famous pillar (discovered in 1902) on which this code is engraved also depicts at its head Hammurabi (r. c.1955–c.1913 B.C.), the royal lawgiver, as receiving the law from the hand of the sun-god Shamash. The king was regarded as the fountainhead of justice, rendering his judgments under divine inspiration. Under him, however, the administration of justice passed from the priestly class, who officiated in the temples, to secular judges, who sat at the city gates and in the market places. Litigants could appeal to the prime minister and even to the king himself. (See HAMMURABI, THE CODE OF.) The procedure remained practically unchanged to the time of Darius the Great (r. 521–486 B.C.).

Both in Egypt and in Mesopotamia the keeping of careful records of judicial proceedings made possible the development of a system of case law. Thousands of these records give a vivid and authentic picture of the people's life in these ancient kingdoms.

Hebrew.—Another society claiming the sanction of divine law is that of the Hebrews. We are told that Moses (13th century B.C.) received from Jehovah the two tables of the law "written with the finger of God," and that he "sat to judge the people from the morning unto the evening, because," as he said, "the people come unto me to inquire of God; when they have a matter they come unto me; and I judge between a man and his neighbor, and I make them know the statutes of God, and his laws." But the pressure of the

work compelled Moses to delegate part of his judicial functions to inferior judges, who "judged the people at all seasons; the hard causes they brought unto Moses, but every small matter they judged themselves" (Exodus 18:13-26).

When the Israelites fell upon evil days, "Jehovah raised up Judges who saved them out of the hands of those who despoiled them" (Judges 2:16). But these judges were not so much judicial officers as charismatic leaders of the nation. Deborah, the first female judge, judged the people of Israel, who "came up to her for judgment . . . under the palm tree . . . between Ramah and Beth-el" (Judges 4:5). Samuel was a judge all the days of his life and in his old age made his sons judges. He judged the people in his house at Ramah and "went from year to year in circuit to Beth-el, and Gilgal, and Mizpah" (I Samuel 7:15-8:1).

The astounding victories of Saul made him the hero of the Israelite tribes and raised him to a kind of glorified and regal judgeship (c.1025 B.C.). David also served as king, judge, and military leader (1013-973 B.C.). We are told that when Solomon became king (973 B.C.), Jehovah appeared to him in a dream by night and bade him ask what He should give him. The young king prayed that he might have "an understanding heart to judge the people and that he might discern between good and evil" (I Kings 3:5-9). Jehovah granted his prayer. His handling of the dispute between the two women for the possession of the child of one of them proved to the people that "the wisdom of God was in him, to do justice" (I Kings 3:16-28).

The Greek rulers who ruled Palestine after Alexander's conquest of the East and his death (323 B.C.) gave their Jewish subjects a large measure of self-government. Under them there was instituted the Synhedrion (Heb. Sanhedrin, q.v.), composed of 71 members chosen from the sacerdotal aristocracy and from the schools of religious law. Even under the Roman occupation (from 64 B.C.) the Sanhedrin enjoyed considerable independence as a legislative, executive, and judicial body. Its procedure as the supreme judicial court of the Jews was meticulously guarded and regulated.

Hindu.—Two systems of law, which their adherents claim to be divinely revealed, prevail over wide areas of the world and over large populations. These are the Hindu and the Mohammedan. Indo-Iranians from the northwest poured over the Indian subcontinent (1500-1200 B.C.) and imposed upon the original Dravidian inhabitants their laws, said to have been promulgated by the man-god Manu (q.v.). To these laws King Asoka, who ruled over most of India (273-232 B.C.), added the moral code of Siddhartha Gautama (563?-483 B.C.) known as Buddhism. (See *Buddha* and *Buddhism*.) He decreed that complainants could call upon him at any time and that any dispute or fraud should be brought forthwith to his notice.

After Buddhism had been banned from India (c.800 A.D.), the Buddhistic system continued only in the countries to which Buddhist monks had carried their religion: Burma, Ceylon, Siam, Cambodia, Annam. Buddhist law was exalted to the status of a divine pronouncement in Tibet, where the government still is administered by a priestly hierarchy, at whose head is enthroned the Dalai Lama in Lhasa.

After the banning of Buddhism, the justice

of the ruler in the hundreds of independent states of India under the Brahman (see *BRAHMANISM*) system was personal. He alone had the power of life and death; he could dispose of his subjects' property and persons. When he heard cases, he was attended by learned Brahmans whose presence made his justice divine.

During the centuries of organized and effective Mohammedan rule (1206-1707)—first by the Turks and then by the Mongols—the Brahman law was largely displaced. After India during the 18th century had come under British rule, the old law was restored to its former position of authority (1788) and Hindu pundits advised British judges in all law suits involving Hindus. British district commissioners, thoroughly versed in Hindu law and custom and familiar with the language, visited the villages, administered their affairs, heard complaints, and pronounced judgment in the speedy and personal manner which Orientals so greatly admire. See also *INDIA*, *SUBCONTINENT OF—Law*.

Mohammedan.—The most vigorous of all nomistic systems is the Mohammedan. The law is contained in the Koran, or word of God, as written by Mohammed (570-632, q.v.), in Mohammed's sayings and conduct, as preserved by tradition, and in the treatises of the muftis (jurisconsults). Within little more than a century after Mohammed's death the new faith, known to its adherents as Islam, spread from its Arabian home to India in the east and to Spain in the west. In Granada the Arabs built the Alhambra with its Hall of Justice and Gate of Justice; in Córdoba, the Gate of Pardons. In Córdoba and Seville they established the greatest universities and libraries to be found then in Europe. Education in the law was imparted here and at the universities in Cairo, Isfahan, Damascus, Bukhara, and Stamboul.

By 900, Arab jurists learned to separate the judicial from the executive function and developed a professional body of specialists who organized an elaborate system of legal theory. From the law schools were recruited the judicial officers, of whom the cadis (inferior magistrates or judges) are the best known. The schools also furnished the muftis (jurisconsults), who prepared and submitted opinions on pending cases, counseled clients, and advised on executive and legislative matters.

The Assembly of the Turkish Republic in 1924 adopted a new constitution, abolished the old courts of Islamic law, declared the separation of law from religion, and replaced the old laws with codes founded on Romanesque models. But in many communities from West China and Borneo to Morocco, from the Mediterranean to Kano and Tanganyika, the religious law still holds sway and the cadis continue to administer justice in the mosques and in the market places.

Chinese.—By way of contrast with these nomistic systems is the secular system of the Chinese—a system which probably antedates all those previously discussed and is the world's oldest living system.

For 4,000 years the Chinese were content that all executive, legislative, and judicial powers should be combined in the same officials. At the base of the system was the *chih-hsien* (magistrate of the *hsien*, or county). This official decreed the necessary ordinances for his district, levied and collected taxes, made public improvements, adjudicated disputes, maintained peace and order,

and served as moral guide and censor, frequently admonishing the people subject to his jurisdiction on their duties to heaven, to the emperor, and to each other. Above him were the prefect, the provincial governor, the viceroy, and, finally, the imperial court at Peking. It was essentially a government of men, not of laws. Confucius (c.551-479 B.C., q.v.) emphasized rule by personal example: "Guide the people by law, subdue them by punishment; they may shun crime, but will be void of a sense of right; guide them by example, subdue them by courtesy; they will learn right, and come to good."

In 1911 the overthrow of the last of China's long list of dynasties marked a turning point in Chinese polity. In 1912 a "Provisional Compact" was adopted and a new judicial system was inaugurated. In 1928 new civil and criminal codes were published. In 1936 a Final Draft Constitution of the Republic of China was promulgated and was adopted by the National Assembly in 1947. The Final Draft Constitution defines legislative, executive, and judicial powers, though there is no express prohibition of overlapping. However, since the performance of judicial functions by the district magistrates proved unsatisfactory, a program to relieve them of their judicial functions was undertaken. This was successful in most of the provinces, but how it has fared since 1949, when the People's Government was proclaimed, is unknown.

Greek.—The earliest picture which we have of a judicial proceeding in a secular society is that which Hephaestus wrought upon the shield which he made for Achilles. Homer describes the scene as depicted on the shield (*Iliad*, XVIII, 497-508):

"... a multitude
Was in the market-place, where a strife went on,—
Two men contending for a fine, the price
Of one who had been slain. Before the crowd
One claimed that he had paid the fine, and one
Denied that aught had been received, and both
Called for the sentence which should end the strife.
The people clamored for both sides, for both
Had eager friends; the heralds held the crowd
In check; the elders, upon polished stones,
Sat in a sacred circle. Each one took,
In turn, a herald's sceptre in his hand,
And, rising, gave his sentence. In the midst
Two talents lay in gold, to be the meed
Of him whose juster judgment should prevail."

Apart from conditions at Athens, for which we have good information, too little is known about courts in other Greek city-states, where the system varied from city to city, to warrant more than the statement that juries of citizens eventually superseded the crowds described by Homer.

Aristotle (384-322 B.C.), in his *Constitution of Athens*, tells in detail how Athenian juries were selected in his time. Annually a jury list of all male citizens above 30 years of age was arranged; from this list juries for the different law courts were chosen by lot. For ordinary cases a panel of 500 names was drawn; for more important cases the jury might number 1,000 or even 1,500.

Greek juries were sole judges of both law and fact; the magistrate who presided at a trial had no power to instruct on the law and there was no appeal from the verdicts. The procedure furnished no precedents for the development of a system of case law and produced neither lawyers nor juriconsults, but afforded an unparalleled opportunity for the development of forensic oratory. To it we owe such supreme examples of inspired eloquence as Plato's (*Socrates*) *Apology* (399 B.C.) and Demosthenes' *Oration on the*

Crown (330 B.C.). Since every man was required to conduct and to plead his own cause, the procedure gave rise to a profession of speech-writers, many of whose orations, written for others to deliver, are still studied with profit.

Aristotle remarks that in oligarchies citizens were fined for evading jury service, but in democracies were paid for attendance. In this the citizens of democratic Athens were fortunate: they received three obols (a substantial income) for each case which they heard and they had an opportunity in the market place, in the assembly, or in the courts to indulge in their favorite pastime, "either to tell or to hear some new thing" (Acts 17:21).

Roman.—Since the greatest legacy of ancient Rome is its law, under which—whether pure or blended—almost one half of the civilized world still lives, it is not surprising that of all ancient judicial systems we know most about the Roman procedure as it evolved in its 1,300-year-old ancient history (753 B.C.-565 A.D.). Our information is comparatively full for the period in which Cicero (106-43 B.C.) was the leader of the Roman bar.

Although the administration of the courts for centuries was the peculiar province of those magistrates called praetors (the praetorship, instituted in 367 B.C., by 180 A.D. reached its maximum strength of 19 annually elected members), yet the Romans never insisted on the sharp separation of judicial from executive and legislative functions. Both in the kingdom (753-509 B.C.) and in the empire (27 B.C.-476 A.D. for the west; 1453 A.D. for the east) the king and the emperor performed the chief judicial, executive, and legislative functions, while in the republic (507-27 B.C.) some of the executive magistrates (such as consul, praetor, aedile, censor, plebeian tribune, provincial governor) had judicial duties and the legislative organs (particularly the senate and the centuriate assembly) occasionally acted as courts.

Since it was only infrequently that a magistrate or judge was expert in the law, he was assisted by jurists whose advice he was free to accept or to reject. Such technical advisers (pontiffs until c.250 B.C., juriconsults afterward), whom he himself chose, were called collectively his *consilium*, which in the empire evolved into the emperor's consistory. Many of the interpretations (*responsa*) of these lawyers—whether given to judges or to litigants, for they served private persons as well in all legal activities—attained an authority no less than that of the law itself and eventually were incorporated into Justinian I's (r. 527-565) *Digest*, which received statutory force in 533 A.D.

As the business of the courts increased, a corps of judicial assistants (*apparitores*)—clerks, cashiers, criers, bedels, registrars, messengers—evolved.

In the late empire the state recognized Christian (from 318 A.D.) and Jewish (from 398 A.D.) courts as competent to settle cases in private law brought before such tribunals by adherents to Christianity or to Judaism. Secular execution was accorded to sentences delivered in these courts.

Civil Procedure.—To bring a private law suit to trial the prospective litigants appeared before a magistrate to satisfy him that the case was worthy of a hearing. If their evidence convinced the magistrate (usually a praetor) that the suit

was admissible, the litigants were offered the choice of alternatives: trial either by a single judge (or at most five referees) or by a panel of jurors numbering 105 (later 180). When this choice had been made, the magistrate then determined the nature of the claim, fixed the conditions under which the case should be heard, and sent the suit to the chosen judge or jury for trial.

The judges were popular referees, selected by the litigants from a list of citizens compiled by the principal (urban) praetor. Like the magistrate himself, these judicial delegates were not necessarily trained in the law, but were free to seek the advice of juriconsults. Three types of people's judges are distinguished: (1) the *iudex* heard cases in which a fixed sum was claimed or could be awarded as a penalty; (2) the arbiter tried suits wherein an indefinite amount would be assessed by an estimate of circumstances; (3) the *recuperatores* (always three or five) were used originally (before 242 B.C.) in cases to which aliens against citizens or against aliens were parties, but later also in cases in which citizens desired speedy settlements of compensation or of restitution. These judges sat singly (save for the *recuperatores*), ruled on admissibility of testimony and of evidence, and pronounced judgment.

Criminal Procedure.—Suits involving crimes and acts affecting adversely public policy, welfare, and security were tried in Cicero's generation in one or another of 10 so-called standing courts (*quaestiones perpetuae*), over which praetors presided and in which jurors served.

As in civil procedure, the first step was to request a magistrate (usually a praetor) to permit the action to be brought, for there never was a public prosecutor in Rome and it was left to aspiring politicians or to patriotic barristers to prosecute persons suspected or known to have committed crimes. If more than one accuser appeared for a single offense, a preliminary oratorical argument, wherein each aspirant attempted to prove his prowess, entertained the jurors, before whom the case later would be tried and who theoretically voted for the best candidate in the contest.

The urban praetor annually arranged a jury list of about 1,000 names of upper-class citizens, who were divided into panels of uncertain (to us) strength. From these panels, assigned in rotation to courts, were selected by lot more jurors than would be needed for a given case, that enough after challenge might remain to hear the suit. Voting could be open or by ballot. Three possible verdicts were: (1) not proved, (2) acquittal, (3) condemnation. A two-thirds vote was necessary to find the first verdict, but a majority of votes decided the last two verdicts; a tie vote resulted in acquittal. See CIVIL LAW.

Germanic.—The administration of justice among the Germanic tribes, as described by the Roman historian Tacitus in his *Germania* (98 A.D.) was secular. A tribe's general assembly selected chiefs, each aided by 100 assessors (*Schöffen*), to administer law in villages. The assembly apparently heard only criminal cases, in which the guilty either received a capital penalty or paid a fine in livestock.

The Germanic invaders imported this procedure into Gaul (France), whose Romanized inhabitants for the most part continued to live under Roman law as they had known it. The Merovingian kings of the Franks (481-742) favored their subjects by imitating Roman ways to

the extent of even sitting to adjudicate law suits. Dagobert I (r. 628-638), the most powerful of the Merovingians, took an active part in the administration of justice.

The later Merovingian kings divided the country into counties, over which they appointed officials known as counts. These served not only as executives and administrators, but also as judges over both Franks and Gallo-Romans. In the exercise of their judicial functions they were assisted by lay judges (*Schöffen*).

Charlemagne (r. 768-814) sent out special judges (*missi regii*) to hold assizes in the various districts of his empire and to inquire into maladministration of justice.

French.—After Charlemagne's death his centralized empire disintegrated into a myriad of feudal fragments. The administration of justice passed into the hands of feudal lords of three different grades of jurisdiction (high, middle, low, of which the high alone possessed the power of life and death). The law differed from barony to barony, but knowledge of the law was not regarded as indispensable and issues of fact were frequently ordered tried by combat.

Philip Augustus (r. 1180-1223) undertook the task of reintegrating the feudal fragments. He established royal courts of justice in his own feudal domains and in every barony on its reunion to the crown. Certain cases, designated royal, were withdrawn from baronial courts. In every case, unless the defendant objected, the royal court proceeded to exercise jurisdiction. Louis IX (r. 1226-1270) promulgated the code known as the Establishments, which fixed procedural rules. Appeals lay to the supreme council (court of peers), whose members in the following century were mostly men learned in law. By the end of the reign of Louis XV (r. 1723-1774) there were 13 parliaments and 4 provincial councils, which pronounced royal judgments in civil and criminal cases, and more than 300 courts of first instance. The Constituent Assembly abolished (1791) the parliaments and the old royal courts and in their place created for each department of France a criminal court with a jury, for each district a civil court, and for the whole kingdom the Court of Cassation over these courts of first instance.

Anglican.—The Jutes, the Angles, and the Saxons, who invaded England, after the Roman legions had been withdrawn (410 A.D.), brought with them their Germanic traditions, customs, and institutions. As the tribal communities which they established became united in kingdoms—(at one time there were seven kingdoms—the Heptarchy—in the island), new districts, known as shires, midway between the administrative and judicial unit of the hundred and the folkmoor of the kingdom, were created. After the several tribal kingdoms had been united into one kingdom the shiremoot, later known as the county court, exercised a general jurisdiction and was also the governing authority of the shire.

The only royal and national court was the Witenagemot (q.v.), over which the king presided, but it was accessible only to nobles and to those who had resorted to the moots of hundred or of shire and had been denied redress. Besides being a judicial tribunal the Witenagemot exercised legislative, executive, and administrative functions. Jury trial was unknown. Issues of fact were tried by the ordeals of hot iron, where the suspected person was a freeman, or of boiling

water, where he was a villein, or by compurgation, wherein a party obtained oath-helpers (usually 12 in number) to swear either to the truth of his plea or merely to their belief that he had sworn to the truth. The judicial system of Anglo-Saxon England thus was characterized by decentralization.

After the Norman Conquest (1066 A.D.) the new king, William I (r. 1066-1087), substituted the *Curia Regis* (q.v.) for the Witenagemot as a general executive, legislative, and judicial body. He also added trial by battle to the Anglo-Saxon procedures. Under him and his successors, particularly Henry II (r. 1154-1189), the judicial system was centralized, with the king at its head. The *Curia Regis* followed the king's person, but with the completion of Westminster Hall as the king's palace in 1099, the *Curia Regis* had a definite abode, and after 1300 (for nearly 600 years) Westminster Hall served as the central seat of justice for the realm. *Magna Charta* (1215), indeed, stipulated that legal suits should no longer follow the ambulatory royal court, but should be tried in some fixed place.

From the *Curia Regis* were evolved the central courts of original jurisdiction: (1) the Court of Exchequer, organized c.1118; (2) the Common Pleas, originally known as the Bench, or Common Bench, created in 1178; (3) the King's Bench, instituted in 1268.

Court of Exchequer.—This court originally was concerned only with the royal revenues, but in time its jurisdiction was extended to all actions between subjects except those involving claims concerning lands. This was accomplished by permitting a plaintiff to plead that he was indebted to the king and that the defendant was withholding what he owed him (the plaintiff) by reason whereof he was less able to pay the king. Upon such an allegation, of which no denial was permitted, the plaintiff could sue out a writ of *quominus* and bring his adversary into the king's court.

Court of Common Pleas.—Sir Edward Coke (1552-1634), who in 1606 became lord chief justice of the Common Pleas, declared that court to be "the lock and key of the common law." He fought valiantly for its independence and power against what he considered to be the encroachments of the Court of Chancery, the Court of King's Bench, the ecclesiastical courts, and the royal prerogative. The Common Pleas was the great court of original jurisdiction in civil actions, both real and personal, between subjects.

Court of King's Bench.—The King's Bench was the great criminal court. It also had jurisdiction of all pleas of the crown, civil actions involving force or in which the king was plaintiff, and actions of replevin. It finally exercised an appellate jurisdiction over the other two common law courts.

Trial by Jury.—The characteristic feature of common law trials was the jury. This important institution probably had its origin in the administrative practice in parts of France (with which the Norman kings of England were familiar), whereby men of the vicinage were called to declare on oath their knowledge as to certain matters, such as ancient landmarks, family history, and kinship. Later a select number was substituted for the community; these gave their testimony on oath and were called the *jurata*. A jury was thus in origin a group of sworn witnesses and it continued in this character for sev-

eral centuries. This institution, obscure in its origin, has become the prized palladium of civil liberties and rights wherever the Anglican system has spread.

The United States Constitution guarantees trial by jury in criminal cases by the 6th Amendment and in civil cases by the 7th Amendment. Most state constitutions contain similar guarantees.

In France there was no trial by jury until 1791; in that year an act of the Constituent Assembly gave the right of such trial in criminal cases. This was preserved in the *Code Napoléon* (1804); at the same time the code provided for the selection of jurors by means largely under the executive's control or influence. Other countries followed the example of the code, but in none of them does the jury occupy so important a place as in the Anglo-American systems. Today the only court in France which sits with a jury is the *Cour d'Assises*, before which major offenses (*crimes*) are tried.

Other Courts.—The courts which have been described did not, however, exhaust the well springs of royal justice, and from time to time other courts were established to supplement the common law justice. Among such courts, created in the exercise of the royal prerogative, are the Court of Chancery, the Court of Star Chamber (abolished 1641), the Courts of Admiralty, and the ecclesiastical courts following the Reformation.

Ecclesiastical Courts.—In England during medieval times—as in most of the countries of western Europe—the church had its own ecclesiastical courts. These constituted a complete judicial system in themselves. From judgments in diocesan and archdiocesan courts appeal lay to the Roman Curia. These ecclesiastical courts administered a law of their own, the canon law, derived in part from Roman law. They had jurisdiction to enforce discipline within the church and religious orders and over spiritual offenses by laymen. Ultimately they acquired jurisdiction over marriage, divorce, probate of wills, and administration and settlement of estates.

William I and his successors in England claimed that appeals from the ecclesiastical courts within the realm properly lay to the sovereign as the supreme authority in spiritual as well as in temporal matters—a claim which the church vigorously combatted, with the result that King John in 1213 was compelled to acknowledge the supremacy of the pope. But the struggle did not end there. The statutes of *praemunire* (27 Edward III, St. 1, c.1 [1353]; 16 Richard II, c.5 [1392-1393]) imposed severe penalties upon resort to Rome in derogation of the jurisdiction of common law courts. After Henry VIII had broken with Rome, Parliament passed the Act of Appeals (1533) providing that all spiritual cases should be determined within the king's jurisdiction and not elsewhere. Otherwise the structure and jurisdiction of the ecclesiastical courts was little changed until 1857, when jurisdiction over annulment and divorce *a mensa et thoro* was vested in the Court for Divorce and Matrimonial Causes, and in probate matters in the Court of Probate (20 and 21 Victoria, c.77). The Judicature Act of 1873 (36 and 37 Victoria, c.66) and the Supplemental Judicature Act of 1875 (38 and 39 Victoria, c.77) vested this jurisdiction in the Probate, Divorce, and Admiralty Division of the High Court of Justice.

Other European countries followed the English example. In France a series of statutes curtailed the jurisdiction of the ecclesiastical courts, until the National Assembly (1790) abolished such courts. Today the Roman Curia in its several congregations and tribunals exercises final jurisdiction only in matters of faith and morals affecting the clergy (both secular and regular) and the laity of the Roman Catholic Church.

Court of Chancery.—The chancellor was originally an executive, the chief official of the Exchequer. As lord keeper of the Great Seal, which was required to authenticate all state documents, he controlled the issuance of writs which were required to start the wheels of justice moving in the courts of Exchequer, Common Pleas, and King's Bench. However, by the reign of Edward II (1307-1327) he was exercising judicial functions and by 1350 his office had developed into the Court of Chancery—a court which by reason of the royal prerogative could afford relief above and beyond the competence of the common law courts. Unlike the common law courts, which functioned only in regular terms, the Court of Chancery was always open. Upon the filing of the bill setting forth complainant's grievance—and no charge was made for filing—a subpoena was issued directing the respondent to appear and answer upon oath complainant's allegations. The chancellor heard the case without a jury and passed on all questions of law and fact. The judgment was known as a decree—a personal command that the respondent do, or refrain from doing, specified things.

Courts of Admiralty.—In the 14th century the king began to appoint admirals, who soon began to exercise judicial powers. Early in the next century a single lord high admiral of England was appointed and a prerogative court of admiralty jurisdiction was established in London. With the Age of Discovery, the exploits of English buccaneers on the Spanish Main, and the presence of English shipping on all the Seven Seas, the power and prestige of this court increased, until it encountered the opposition of the common law courts. During the 17th century it suffered an eclipse, but, with the Industrial Revolution and the increased importance of overseas commerce in the 18th and 19th centuries, it regained its former jurisdiction.

Appellate Courts.—The ultimate appellate authority is the House of Lords. Until 1844 each member of the House was a judge, but in that year the famous case of *Daniel O'Connell v. the Queen* established the rule that only law lords (that is, those holding or having held high judicial office) should vote as judges, and this has ever since been the practice.

Privy Council.—By the Judicial Committee Act of 1844, Parliament gave statutory recognition to the prerogative authority of the Judicial Committee of the Privy Council to hear appeals from any court of justice of the British colonies and possessions. Later acts, however, have tended to limit such appeals to those from the highest courts of the several provinces or states or dominions. The tendency has been for the commonwealths to limit or to abolish such appeals.

Procedural Reform.—As is true of all institutions when the creative impulse has exhausted itself, the Anglican system of common law and chancery procedure, like an ocean-going craft, gathered barnacles with the years. Common law pleading became more technically evasive and

dilatory; an action began with the declaration in which the plaintiff couched his claim in approved legal jargon, but this was followed by interminable other pleadings designed, theoretically, to entrap that elusive concept, the issue; thus there followed the plea, the replication, the rejoinder, the surrejoinder, the rebutter, and the surrebutter.

By contrast, at its inception, the chancery practice seemed simple indeed. This circumstance encouraged resort to the chancery court and the chancellor was swamped with business. This necessarily retarded his work and by the 1800's the accumulation of arrears was such that it took years to get a suit through the court. Charles Dickens (in 1852) published his *Bleak House*, in which he satirized the chancery practice by portraying the case of Jarndyce and Jarndyce "with its bills, cross-bills, answers, rejoinders, and the mountains of costly nonsense that had accumulated on it." Meanwhile, as Dickens says, innumerable children had been born into the case; innumerable young people had married into it; innumerable old people had died out of it—and no one knew what the case was about or who the real parties were; no one had ever seen them.

Even before Dickens had written his *Bleak House*, the cumbersomeness of the dual system of courts of law and equity and the inadequacies and abuses of the procedures of these courts challenged the attention of publicists, members of Parliament, and royal commissions. The Field Code of Procedure (discussed later) pointed the way and some reforms were introduced, but it was not until 1869 that a complete overhauling of the judicial system was seriously considered. In that year the Royal Judicature Commission reported that "the first step towards meeting and surmounting the evils complained of would be the consolidation of all the courts of law and equity into one court, in which would be vested all the jurisdiction exercisable by each and all the courts so consolidated." Parliament passed the Judicature Act of 1873 and then the Supplemental Judicature Act of 1875, which abolished the old courts and substituted a Supreme Court of Judicature, consisting of the High Court of Justice and the Court of Appeal. Since the Act of 1881 the High Court of Justice has functioned in three divisions: (1) Chancery, (2) King's Bench, (3) Probate, Divorce, and Admiralty.

United States.—The British colonists brought with them to America the common law as they had known it and also modified replicas of the judicial system of England. Separate courts of law and of chancery were established in all the colonies, though in Massachusetts and Pennsylvania the discretionary jurisdiction of the chancellor was so repugnant to the Puritan and Quaker concepts of a justice of law rather than of men that those colonies early rejected both the chancery court and its jurisdiction. It was not until 1836 and 1877 that equity jurisdiction was adopted in Pennsylvania and in Massachusetts, respectively. Although all jurisdictions in the United States now recognize equity as a fundamental element in their jurisprudence, only a minority of the states retain the separate chancery courts.

State Courts.—After the separation from the British crown (1776) the colonial courts became courts of the several states without any great changes in jurisdiction, procedure, or even personnel. Decisions of English courts continued

to be cited by United States judges and lawyers and the treatises of English jurists furnished the basic study for aspirants to the bar. But with these benefits were associated some of the very evils which were developing in the English dual system of courts of law and equity. Soon after his admission to the bar of New York, David D. Field (1805-1894) became convinced of the need for reform and thereafter devoted himself unremittingly to the task of interesting members of the bar, civic organizations, and legislative committees in the project. In 1847 he was appointed head of a state commission to revise the practice and procedure of the courts of New York. In 1848 the commission reported a code of procedure (enacted into law in the same year), which substituted for the old dual system one in which law and equity were administered by the same courts and under a common and simplified procedure. The code, known as the Field Code of Procedure, has since been adopted with modifications by most of the states of the Union.

The judicial systems of the several states present, generally, a common pattern. At the first tier of the judicial hierarchy are inferior courts of limited jurisdiction, such as the courts of justices of the peace, municipal courts, and recorders' courts. Above these are courts of general jurisdiction variously designated, in the different states, as courts of common pleas, circuit courts, or superior courts, and in New York as the supreme court. Above these are courts of intermediate or final appellate jurisdiction, the latter generally known as supreme courts. Probate and testamentary matters and matters involving testamentary trusts are handled by courts variously designated probate, surrogate, or orphans' courts.

The most significant development in the United States judicial system in recent years has to do with children. On July 1, 1899, there went into effect a statute of Illinois which established in Chicago the first juvenile court in the world. This law revolutionized the treatment of delinquent and neglected children. Dean Roscoe Pound declared the inauguration of the Chicago court to be "the greatest advance in judicial history since Magna Charta." In 1899 Judge Ben D. Lindsey organized in Denver, Colo., under a school law, a juvenile court and in 1903 secured the passage of a juvenile court act similar to that of Illinois and also of an act giving the juvenile court jurisdiction to deal directly with parents and other adults contributing to delinquency or dependency under either chancery or criminal procedure. He continued to be for many years a protagonist of the juvenile welfare movement. Today every state in the American Union has a juvenile court law and such laws exist in more than 30 foreign countries, though many of them are limited and imperfect.

Federal Courts.—The Constitution (Art. 3, sect. 2) defines in nine categories of cases and controversies the extent of the judicial power of the United States. Congress cannot confer jurisdiction beyond the extent of the power so defined nor can a federal court exercise jurisdiction beyond what Congress confers within the limitations of the Constitution. All federal courts are, therefore, courts of limited jurisdiction.

Article 3, section 1, created the Supreme Court, though it left its membership and organization to Congress. The Judiciary Act of 1789

provided for a chief justice and five associate justices. Since then, at different times, the number of associate justices has been 6, 8, and 10. The Act of April 10, 1869, fixed the number of associate justices at eight, and that has been the number ever since.

Article 3, section 2, provided that in all cases affecting ambassadors, other public ministers, consuls, and those in which a state shall be a party, the Supreme Court should have original jurisdiction and that in all other cases it should have appellate jurisdiction, with such exceptions and under such regulations as Congress should make. The Supreme Court now has jurisdiction of direct appeals from judgments of district courts holding an act of Congress unconstitutional; from decisions of district courts granting or denying, after notice and hearing, an interlocutory or permanent injunction in any civil action required by act of Congress to be heard and determined by a district court of three judges; from decisions of courts of appeals holding invalid a state statute as repugnant to the Constitution, treaties, or laws of the United States; from judgments of the highest courts of the several states when declaring invalid a treaty or a statute of the United States, and from final judgments upholding the validity of state statutes against the contention of repugnancy to the Constitution, treaties, or laws of the United States. Other cases reach the Supreme Court only as a matter of grace, that is, upon the allowance by the court of what is called a petition for a writ of certiorari directed to the lower court.

The Judiciary Act of 1789 divided the territory embraced in the states into 13 districts, organized in 3 circuits. It provided a circuit court and a district court for each district, the former presided over by two justices of the Supreme Court sitting with the district judge. The district court was presided over by the district judge alone. Since this work on the circuits proved very burdensome to the justices, subsequent statutes relieved them of a large part of their circuit duties. Finally the Circuit Court of Appeals Act of March 3, 1891, relieved the justices of all trial work. The Act of March 3, 1911, abolished the circuit courts and transferred their jurisdiction to the district courts. In 1952 there were 85 district courts within the continental United States.

The Circuit Court of Appeals Act (1891) provided an intermediate tier of appellate courts between the circuit and district courts and the Supreme Court. It divided the country into nine circuits, in each of which it created a court of appeals consisting of three circuit judges. The circuits were increased to 10 in 1929 and to 11 in 1948.

The procedure in actions at law in the federal courts, beginning with the Temporary Process Act of 1789 and until Sept. 1, 1938, generally conformed to the procedure of the courts of the state in which they sat. Suits in equity, however, were governed by equity rules promulgated from time to time by the Supreme Court. The English separation of law and chancery was thus perpetuated, although the same judge heard both classes of cases.

On June 19, 1934, Congress passed an act (48 Stat. 1064) authorizing the Supreme Court to prescribe uniform rules of procedure for both actions at law and suits in equity. The court

appointed an advisory committee to assist in drafting the rules. A complete set of rules was reported to Congress on Jan. 3, 1938, and, there being no objection by Congress, the rules, known as the Federal Rules of Civil Procedure, went into effect on Sept. 1, 1938. They are framed largely along the lines of the English rules under the judicature acts of 1873 and 1875. A new title 28 of the United States Code, under the heading "Judiciary and Judicial Procedure," became effective Sept. 1, 1948 (62 Stat. 869). On the same day a new title 18 of the code, under the heading "Crimes and Criminal Procedure," also became effective (62 Stat. 684).

Besides the Supreme Court, the courts of appeals and the district courts—generally referred to as "constitutional courts"—there are (1) the United States Court of Claims, having jurisdiction of claims against the United States; (2-3) the Customs Court and the Court of Customs and Patent Appeals: the former with jurisdiction of cases involving customs laws and regulations, the latter with jurisdiction by appeal from judgments of the Customs Court and from decisions of the Patent Office; and (4) the Tax Court, having jurisdiction of cases under the internal revenue laws.

Courts-martial; Military Commissions and Tribunals.—Members of the armed forces of a state are subject to the articles of war promulgated by that state and for their infraction may be tried by courts-martial or by military commissions convened in the manner and pursuant to the procedure which the state has prescribed. Enemy combatants guilty of violations of the common law of war are tried by military commissions in accordance with that law.

On Aug. 8, 1945, the governments of the United States, France, the United Kingdom, the Union of Soviet Socialist Republics entered into an agreement for prosecution and punishment of the major war criminals of the European Axis. Annexed to the agreement was the charter of the International Military Tribunal setting forth its constitution, jurisdiction, power, and procedure. Twenty-two major Nazi war criminals were tried before the tribunal—the first time in history that legal proceedings had been instituted against the leaders of an enemy nation.

International Courts.—The increasing use of arbitration in the settlement of international disputes was an important development of the 19th century. The outstanding example was the Alabama Claims Arbitration (1872) involving demands on the part of the United States arising from alleged violations of neutrality by Great Britain during the Civil War. It resulted in a decision requiring Great Britain to pay to the United States the sum of \$15,500,000.

The First Peace Conference (at The Hague in 1899) adopted a convention on the pacific settlement of international disputes which codified the law and practice relating to good offices, mediation, and arbitration, and provided for a Permanent Court of Arbitration. The Second Peace Conference (at The Hague in 1907) revised the convention and provided a panel of eminent jurists from which a court might be selected to arbitrate any dispute between signatories of the convention.

Since these arbitral tribunals were not courts in the proper sense, the Versailles Peace Conference of 1919 decided that a Permanent Court of International Justice should be established, but

left to the Council of the League of Nations the details of its creation. The court held its first session at The Hague in 1922 and until the invasion of the Netherlands in 1940 had heard 65 international cases, rendered 32 judgments, 27 advisory opinions, and issued over 200 orders.

The United Nations came into being on Oct. 24, 1945, when its charter, drafted and signed at the United Nations Conference on International Organization at San Francisco from April 25 to June 26, 1945, had been ratified by a majority of the signatory states. The charter established as one of the principal organs of the United Nations an International Court of Justice. Only states can be parties to cases before the court. This compulsory jurisdiction of the court has been accepted by 37 states.

GUSTAVUS OHLINGER.

COURT, Presentation at, a formal presentation to the sovereign of Great Britain of persons whose official, social or intellectual standing entitles them to that honor. It takes place either at St. James's Palace, at a levee, intended for gentlemen only, or at Buckingham Palace, a drawing room, where both ladies and gentlemen appear. The days when levees and drawing rooms are to be held are always announced some time beforehand. It is difficult in the present day to define exactly who may and who may not be entitled to be presented. Members of families of the nobility, diplomats, members of the House of Commons, persons holding high offices under the crown, judges, magistrates, church dignitaries, officers in the army and navy, persons who have attained eminence of any kind, foreign ambassadors, members of their staffs and strangers of distinction, and the wives and daughters of the same classes, form the larger number of those presented at levees and drawing rooms. Persons are often presented on entering on some office or attaining some dignity. Any one who has been once presented is entitled to appear at any future levee or drawing room without a new presentation. The whole arrangements connected with presentations are under the supervision of the lord chamberlain, in whose office in St. James's Palace information is given to all persons wishing to be presented. The names of ladies and gentlemen desiring presentation, and of the ladies, noblemen and gentlemen who are to present them, have to be submitted to the sovereign for approval and there is a strict exclusion of persons of damaged reputation, whatever their rank. Court dress or official uniform must be worn. A British subject who has been presented at St.

James's may on any after occasion claim to be presented by the British minister at any foreign court.

COURT BARON, a tribunal originated in medieval England and operated by the lords of manors. This type of court, although feudal in origin, was an important institution in local English government as late as the 16th century and was still alive, though decadent, in the latter part of the 17th century. It declined rapidly in the 18th century, when personal actions initiated in such courts were generally transferred to the courts of common law. The court baron had jurisdiction over matters affecting the lord's rights and the community at large. Personal actions, such as suits for breach of contract, trespass, libel, slander, and assault could be tried there, if the amount involved was 40 shillings or less.

COURT CEREMONIAL, certain forms of international etiquette or usage, which have arisen in Europe during modern times. No independent state can actually have precedence of another; but as the weaker seek the protection and friendship of the more powerful, there arises a priority of rank. The origin of elaborate formalities is to be traced to the Eastern nations, which for ages have practiced various forms expressing reverence for exalted personages. By a gradual establishment of dignities, rank and acts of respect to states, their rulers and representatives, an international ceremonial was formed, that was sometimes the source of confusion and war; to its observance far more consideration was often paid than to the fulfillment of the most sacred contracts. Louis XIV carried this folly further, perhaps, than anyone before or after him. To this international ceremonial belong:

1. Titles of rulers. Accident made the imperial and regal titles the highest, and thus conferred advantages apart from the power of the princes. After Charlemagne, the emperors of the Romans were considered as the sovereigns of Christendom, maintained the highest rank, and even asserted the dependence of the kings on themselves. For this reason several kings in the Middle Ages, to demonstrate their independence, likewise gave their crowns the title of "imperial." The kings of France received from the Turks and Africans a title equivalent to emperor of France. In progress of time the kings were less willing to concede to the imperial title, of itself, superiority to the royal.

2. Acknowledgment of the titles and rank of rulers. Formerly the popes and emperors arrogated the right of granting these dignities; but the principle was afterward established that every people could grant to its rulers a title, the recognition of which would rest on the pleasure of other powers and on treaties. Some titles were therefore never recognized, or not till after the lapse of considerable time. This was the case with the royal title of Prussia, the imperial title of Russia, and the new titles of German princes.

3. Marks of respect conformable to the rank and titles of sovereigns. To the "royal" prerogatives, so-called (conceded, however, to various states which were neither kingdoms nor empires, such as Venice, the Netherlands, Switzerland, and the electorates), pertained such rights as that of sending ambassadors of the first class.

In connection with this there is a much contested point: that of precedence or priority of rank, that is, of the right of assuming the more honorable station on any occasion, either personally, at meetings of the princes themselves, or of their ambassadors, at formal assemblies, or by writing, as in the form and signature of state papers. There is never a want of grounds for supporting a claim to precedence.

As the councils in the Middle Ages afforded the most frequent occasions of such controversies, the popes often intervened. Of the several arrangements of the rank of the European powers which emanated from the popes, the principal is the one promulgated in 1504 by Julius II, through his master of ceremonies, in which the European nations followed in this order: (1) the emperor of the Romans (emperor of Germany); (2) of Rome; (3) of France; (4) the king of Spain; (5) of Aragon; (6) of Portugal; (7) of England; (8) of Sicily; (9) of Scotland; (10) of Hungary; (11) of Navarre; (12) of Cyprus; (13) of Bohemia; (14) of Poland; (15) of Denmark; (16) Republic of Venice; (17) duke of Bretagne; (18) of Burgundy; (19) elector of Bavaria; (20) of Saxony; (21) of Brandenburg; (22) archduke of Austria; (23) duke of Savoy; (24) grand duke of Florence; (25) duke of Milan; (26) of Bavaria; (27) of Lorraine. This order of rank was not, indeed, universally received, but it contained a fruitful germ of future quarrels; some states, which were benefited by the arrangement, insisted upon its adoption, and others, for opposite reasons, refused to acknowledge it. To support their claims for precedence the candidates sometimes relied on the length of time which had elapsed since their families became independent, or since the introduction of Christianity into their dominions; sometimes on the form of government, the number of crowns, the titles, achievements, and extent of possessions, pertaining to each. But no definite rules have been established by which states are designated as being of the first, second, third, or fourth rank. Rulers of equal dignity, when they make visits, concede to each other the precedence at home; in other cases, where the precedence is not settled, they or their ambassadors take turns until a compromise is effected in some way. The "we," by which monarchs style themselves, is used either from an assumption of state or from a feeling of modesty, on the supposition that "I" would sound despotic, while "we" seems to include the whole administration.

COURT DE GEBELIN, kōōr dē gā'blān', Antoine, French scholar, only son of Antoine Court (q.v.); b. Nîmes, France, Jan. 25, 1725; d. Paris, May 10, 1784. He studied theology at Lausanne, and became a pastor of the Reformed Church, but he abandoned the calling for literary pursuits and settled in Paris after 1760. He published *Les Toulousaines, ou lettres historiques et apologetiques en faveur de la religion reformée* (1763), in defense of his co-religionists. In support of American independence he did work for the periodical *Affaires de l'Angleterre et de l'Amérique* (1776 et seq.). His comprehensive study of the languages and mythologies of the ancient world, *Le Monde primitif analysé et comparé avec le monde moderne . . .* appeared in nine volumes published between 1773 and 1784; it was unfinished at his death.

COURT OF APPEALS. See COURT; UNITED STATES—*The Judicial System*.

COURT OF APPEALS IN CASES OF CAPTURE (1780-1787), the chief federal court prior to the establishment of the Supreme Court of the United States. The Articles of Confederation gave Congress "sole and exclusive right and power . . . of appointing courts for trial of piracies and felonies committed on the high seas and establishing courts for receiving and determining finally appeals in all cases of capture, provided that no member of Congress shall be appointed a judge of any of said courts." Congress was also given power to set up *ad hoc* tribunals to settle disputes between the states or between individuals arising out of land grants from different states (Art. IX).

These provisions constituted precedents for the Supreme Court established by the Constitution to remedy what Hamilton called a major defect of the Confederation, the want of a judiciary power (*The Federalist*, 22). This judgment was justified in regard to disputes between the states. Of six such disputes submitted to the Continental Congress, in only one (*Pennsylvania v. Connecticut*) was judgment given, and that did not prevent hostilities between claimants in the territory in question in northern Pennsylvania. The others were finally settled by agreement. In regard to the trial of piracies and felonies committed on the high seas, Congress merely authorized courts of the states to assume jurisdiction. In regard to appeals in cases of capture, the record was somewhat better.

Even before the Articles of Confederation went into force, and even before the Declaration of Independence, disputes had arisen over claims by privateers with commissions from different states or from the Continental Congress. On Nov. 11, 1775, Washington wrote to the president of Congress, "should not a court be established by authority of Congress to take cognizance of prizes made by the Continental vessels?" On Nov. 25, 1775, Congress recommended that the colonies set up prize courts, reserving appeals to itself or to such committees as it might establish. The first appeal was in the case of the schooner *Thistle* on Aug. 5, 1776. Congress at first attempted to deal with the case itself, but finally referred it to a committee of seven, which reversed the condemnation on Sept. 19, 1776. Washington continued to urge that a real court was necessary with adequate jurisdiction. It appears that many of the states had established prize courts, but had greatly limited appeals to Congress. On Jan. 30, 1777, Congress established a standing committee of five to hear appeals in these cases, the members being James Wilson of Pennsylvania, Jonathan Sargent of New Jersey, William Ellery of Rhode Island, Samuel Chase of Maryland, and Roger Sherman of Connecticut. Soon after, James Wayne of New York, John Adams of Massachusetts, and Thomas Burke of North Carolina were substituted for the last three. There continued to be a rapid turnover, and the inadequacies of the committee's authority were obvious, especially in the case of the sloop *Active*. This vessel, captured by the British, was recaptured by the crew and adjudicated by a jury in a Pennsylvania court which divided the proceeds from the sale of the vessel and cargo among several claimants. On appeal, the com-

mittee of Congress reversed the judgment, but the Pennsylvania court ignored this, on the theory that a finding of facts by a jury was definitive. In a resolution of March 6, 1779, Congress declared that captures were to be decided by the law of nations, which is within the power of making war and peace vested in Congress, and called upon the Pennsylvania court to carry out the decision of the committee. This resolution was also ignored, and the appellants did not gain relief until Congress dealt with the matter in 1809 (*U.S. v. Peters*, 5 Cranch 115). The committee thereafter refused to hear further cases.

Congress hesitated to set up a court until the Articles of Confederation went into force. Not until Jan. 14, 1780, when that was assured, did it establish the Court of Appeals in Cases of Capture, with three judges, the first real federal court. There was to be no jury and it was to judge in accordance with "the usages of nations." George Wythe of Virginia, William Paca of Maryland, and Titus Hosmer of Connecticut were appointed judges. Cyrus Griffin was immediately appointed in place of Wythe, who declined to serve. Members of Congress were frequently appointed to the court but, preferring to retain their places in Congress, always resigned before serving, in accordance with the provisions of the Articles.

The court held sessions in Hartford, New York City, Richmond, and Philadelphia. In 1784 Congress considered abolishing the court, as it seemed to have little business since war was over. But this was not done, and the court continued to function until 1787. Prior to its establishment 64 cases had been submitted to congressional committees; 11 of these were decided by the court, which also dealt with 45 other cases. Thus a total of 109 prize cases were considered in the pre-Constitution period, the last being the case of the *Sloop Chester v. the Brig Experiment*, decided on May 1, 1787 (2 Dall. 41). Only eight of these cases have been reported, of which the most important were *Miller v. the Resolution*, 1781 (2 Dall. 1, 19), and *Darby v. the Brig Eastern*, 1782 (2 Dall. 34). These asserted important principles of prize law, such as the necessity of transferring captured neutral property in prize adjudication, the superiority of international law over municipal law in prize cases, and the need of finding evidence to condemn in the vessel itself and its papers.

It is interesting to notice that, as there was a precedent for the Supreme Court of the United States in a federal prize court, so a precedent for the World Court, established in 1920, was found in the International Prize Court provided for by one of the Hague Conventions of 1907, but never actually established.

Consult Davis, J. C. Bancroft, "Federal Courts Prior to the Adoption of the Constitution," *United States Reports*, vol. 131, pp. xix ff. (New York and Albany 1889).

QUINCY WRIGHT,
Professor of International Law, University of Chicago.

COURT OF CHANCERY. See COURT, JUDICIAL; GREAT BRITAIN—28. *Judicial System*.

COURT OF CLAIMS. See COURT, JUDICIAL; UNITED STATES—*The Judicial System*.

COURT OF CUSTOMS AND PATENT APPEALS, U.S. See COURT, JUDICIAL.

COURT OF HIGH COMMISSION, a court which was established in the reign of Queen Elizabeth I, and exercised powers like those which, during the reign of King Henry VIII, had been entrusted to Thomas Cromwell. The judges had the power of arresting suspected persons, imprisoning them, torturing them, and causing them to accuse their confederates or their friends. They could proclaim new articles of faith and impose them on recalcitrant consciences by compulsion of the severest and most odious kind. The court was abolished for abuse of power in 1641.

COURT OF HONOR, a court of chivalry, of which the lord high constable was judge, for the purpose of settling such disputes as had commonly been settled by duels. It was a continuation of what in the time of Henry IV was called *curia militaris*, military court. Suggestions have been made from time to time for the re-establishment of courts of honor, but the law has made provisions for settling larger affairs of offense against honor, such as libel and slander, and the need of a special court is not apparent.

COURT OF LOVE (Fr. *cour d'amour*), in medieval France and Germany, a tribunal composed of ladies illustrious for their birth and talent, whose jurisdiction, recognized only by courtesy and opinion, extended over all questions of gallantry. Such courts existed from the 12th to the 14th century, while the romantic notions of love which characterized the ages of chivalry were predominant. The decisions were made according to a code of 31 articles, which have been preserved in a manuscript entitled *De Arte Amatoria et Reprobatione Amoris*, written by André, royal chaplain of France, about 1170. Some of the troubadours were often present to celebrate the proceedings in verse, and the songs of these minstrels were not infrequently reviewed and judged by the tribunals. Among the ladies who presided were the Countess de Die, called the Sappho of the Middle Ages; Eleanor of Aquitaine and her daughter, Marie, countess of Champagne, and Laura de Sade, celebrated by Petrarch. There was such a court in Provence in the days of the troubadours. The following case was submitted to their judgment: A lady listened to one admirer, squeezed the hand of a second, and touched with her toe the foot of a third. With which of these three was she in love? René I, Duke of Anjou, attempted in vain to revive the courts of love, and the last imitation of them was held at Rueil at the instance of Cardinal Richelieu, to judge a question of gallantry, which had been raised in the Hôtel de Rambouillet.

Consult Reynouard, *Choi. de poésies originales des troubadours*, vol. 2 (Paris 1817); Méray, *La vie au temps des cours d'amour* (Paris 1876); also Paris, G., *Mélanges de littérature française du moyen âge* (Paris 1910).

COURT OF PRIVATE LAND CLAIMS. See UNITED STATES—Judicial System.

COURT OF SAINT JAMES. See SAINT JAMES'S PALACE.

COURT OF THE EXCHEQUER. See EXCHEQUER, COURT OF.

COURT OF THE LIONS. See ALHAMBRA.

COURT PLASTER, so called because originally applied by ladies of the court as patches on the face; black, flesh-colored, or transparent silk varnished over with a solution of isinglass and glycerin, which is often perfumed with benzoin.

COURTELINE, kōōr'tē-lēn', **Georges** (pseudonym of GEORGES MOINEAUX), French humorist: b. Tours, Department of Indre-et-Loire, France, June 25, 1861; d. Paris, June 25, 1929. After spending 14 months in the army, he worked briefly in the civil service. Literary success came with *Les Gaités de l'Escadron* (1886), a humorous portrayal of barracks life. He ridiculed bureaucracy in *Messieurs les ronds-de-cuir* (1893). Most of his life was devoted to the theater. His masterpiece *Boubouroche* (1893), a satire on women, deals with a gullible lover and his mistress. Most of his comedies have a Molièresque flavor, and his *La Conversion d'Alceste* (1905) is frankly imitative of Molière. Many of his novels and stories were also adapted for the stage. He has been called the Mark Twain of France, and resembles the American in his acute and caustic observations concealed beneath a surface of clowning.

COURTENAY, a distinguished English family, probably stemming originally from a French royal line.

WILLIAM COURTENAY (c.1342–July 31, 1396) became chancellor of Oxford University in 1367, a bishop of Hereford in 1370, and bishop of London in 1375. He was archbishop of Canterbury from 1381 until his death. He opposed John of Gaunt, sought to defeat the Lollards, and convened the council in 1382 which condemned the views of John Wycliffe. In 1381 he served as chancellor of England.

His nephew, RICHARD COURTENAY (d. Sept. 15, 1415), served as chancellor of Oxford in 1407 and again from 1410 to 1412. He defended the university in 1411 against the intrusion of Thomas Arundel, Archbishop of Canterbury, but the latter, aided by King Henry IV and Pope John XXIII, won the final victory. In 1413 Richard became bishop of Norwich and treasurer of the royal household of King Henry V.

Richard's grandnephew, PETER COURTENAY (d. Sept. 23, 1492), became bishop of Exeter in 1478, and bishop of Winchester in 1487. The leading part he played in the insurrection of 1483 against King Richard III led to his being attainted, but in 1485 King Henry VII restored him.

A later member of the family, HENRY COURTENAY (c.1496–Dec. 9, 1538), MARQUIS OF EXETER and EARL OF DEVONSHIRE, served King Henry VIII as envoy to France in 1525, later supported him in his divorce proceedings against Catherine of Aragon, and in 1536 was a judge at the trial of Anne Boleyn. The fact that his mother's father had been King Edward IV made him suspect of aspiring to the throne, however, and his correspondence with the king's avowed opponent, Reginald Cardinal Pole, led to his trial, conviction, and execution for treason.

His son, EDWARD COURTENAY (c.1526–September 1556), who had been imprisoned in the Tower of London with his father in 1538, was

released by Queen Mary in 1553 and restored to the earldom. He failed in his attempt to marry the queen, and then interested himself in Princess Elizabeth (later Queen Elizabeth I). He was again imprisoned in the Tower (1554), but in 1555 was released on parole and exiled. He died at Padua, Italy.

COURTESY, in law. See **CURTESY**.

COURTESY TITLE, a title assumed by or given to any person by common consent as an act of courtesy or respect, but to which title the individual has no valid, legal claim. See **TITLES**.

COURTHOPE, kōrt'ūp, **William John**, English man of letters: b. South Malling, July 17, 1842; d. Sussex, April 10, 1917. Educated at Blackheath, Harrow, and Oxford, he was civil service commissioner from 1892 to 1907 and professor of poetry at Oxford from 1895 to 1901. He edited the last five volumes of the standard edition of Pope (10 vols., 1871-1889), which was begun with Whitwell Elwin as editor. His other major work was his *History of English Poetry*, 6 vols. (1895-1910), spanning the period from Geoffrey Chaucer to Sir Walter Scott. His own poetry appeared in *Ludibria Lunae* (1869), *The Paradise of Birds* (1870), and *The Country Town and Other Poems* (1920). He published a life of Addison in 1882, and a series of his Oxford lectures, under the title *Life in Poetry, Law in Taste*, appeared in 1901.

COURTIS, kōrt'is, **Stuart Appleton**, American educator: b. Wyandotte, Mich., May 15, 1874. He studied at the Massachusetts Institute of Technology and the University of Chicago, and received the bachelor's degree at Teachers College of Columbia University in 1919 and the master's degree there in 1921. In 1925 he received a doctor's degree at the University of Michigan. He was director of instruction and dean of Detroit Teachers College, 1920-1925; professor in the school of education at the University of Michigan, 1919-1944, and emeritus professor there after 1944. From 1934 to 1944 he was a part-time professor at Wayne University. He originated the Courtis' "standard tests," a system for measuring the efficiency of school work. He was a member of the Hanus Committee on School Inquiry in New York City (1911-1912); the Gary Survey (1916); and the New York Survey (1924). His writings include *Why Children Succeed* (1925) and *The Measurement of Growth* (1932).

COURTNEY, kōrt'nī, **Leonard Henry**, 1st **BARON COURTNEY OF PENWITH**, English writer and statesman: b. Penzance, Cornwall, England, July 6, 1832; d. London, May 11, 1918. He graduated from St. John's College, Cambridge University, in 1855, and became a fellow in 1856. In 1858 he was called to the bar, but he soon turned to journalism and wrote leaders for the *London Times* from 1865 to 1881. From 1872 to 1875 he was professor of political economy at University College, London. He served as a Liberal and Liberal-Unionist member in the House of Commons from 1876 until 1900, when he was defeated because of his opposition to the Boer War. In 1880-1881 he was undersecretary of state for the Home Department, and in 1881

for the Colonial Office. He became financial secretary to the treasury in 1882, but resigned that office in 1884, when the government failed to accept his proposal for proportional representation. He early opposed Home Rule for Ireland, but later endorsed it and resisted imperialism in every direction. When the Liberals were returned to office in 1906, he was made a peer and sat in the House of Lords. During World War I he urged a negotiated peace. He wrote *The Working Constitution of the United Kingdom* (1901).

COURTNEY, **William Leonard**, English journalist: b. Poona, India, Jan. 5, 1850; d. London, Nov. 1, 1928. He was educated at Oxford University, and was a fellow and tutor in philosophy at New College, Oxford, from 1876 until 1890, when he joined the editorial staff of the *Daily Telegraph*, London. He was literary editor and dramatic critic of the paper until 1924, and editor of the *Fortnightly Review* from 1894. His works include *The Metaphysics of John Stuart Mill* (1879), *Studies in Philosophy* (1882), *Constructive Ethics* (1886), *Life of John Stuart Mill* (1889), *The Feminine Note in Fiction* (1905), and *The Passing Hour* (1925).

COURTOIS, kōōr-twā', **Bernard**, French chemist: b. Dijon, Department of Côte d'Or, France, 1777; d. Paris, Sept. 27, 1838. He was trained in pharmacy, and worked in the laboratory of Count Antoine François de Fourcroy in the École Polytechnique until his induction into the army in 1799. After his discharge he resumed his chemical researches. In 1804 he began work on nitrate of sodium, which is produced by decomposing nitrate of calcium with the carbonate of sodium obtained from kelp. In the course of his operations he observed that iron vessels were corroded if the liquors from which the sodium salts had been crystallized were kept in them for a time. Investigating the cause of this, he found that on distilling the liquors with sulphuric acid a body with a splendid purple vapor was liberated. He examined it and ascertained some of its properties, for instance, its formation of a detonating compound with ammonia, and then gave a specimen of it to Nicolas Clément-Desormes, who read a paper on it, and ultimately resigned the investigation to Joseph Louis Gay-Lussac. This was the first discovery of iodine. In 1815 Courtois' niter factory was ruined, and thereafter he gained a precarious livelihood by making various chemical products.

COURTOIS, **Gustave Claude Étienne**, French painter: b. Pusey, March 18, 1852; d. Paris, Nov. 25, 1923. He was a pupil of Jean Léon Gérôme at Paris and exhibited at the Salon in 1876. He painted *The Death of Archimedes*; *Narcisse* (in the Luxembourg); *Dante and Virgil in Hell*; *La Bayadère* (1882); *The Burial of Atala*; and a number of portraits. At the St. Louis Exposition in 1904 he exhibited *Adam and Eve in Eden*; *Cupid Feasting*; and a portrait of Mme. G. During 1880-1890 he was the most fashionable portrait painter in Paris.

COURTOIS, **Jacques**, French painter, known as **LE BOURGUIGNON** (Italian **IL BORGOGNONE**): b. St. Hippolyte, near Besançon, Feb. 12, 1621; d. Rome, Italy, Nov. 14, 1676. He was a pupil of his father, Jean Courtois, but went to Italy

in 1636 and served three years with the Spanish Army in Lombardy. He then studied at Bologna, Florence, Siena, and Rome, and came under the influence of Guido Reni and Francesco Albani in Bologna, and Pieter de Laar in Rome. He was especially eminent in battle scenes. When his wife died of poison, which he was suspected of having administered, he took the habit of a lay brother of the Jesuits, with whom he remained until his death though he still practiced his art.

His brother GUILLAUME (or GUGLIELMO) COURTOIS (1628-1679) was also an eminent painter who excelled in historical pieces, and assisted Jacques in some of his works. His pictures are to be found in nearly all of the galleries of Europe.

COURTSHIP OF ANIMALS. In sexually reproducing animals successful reproduction can be attained only if individuals can recognize members of their own species and differentiate between the sexes. In many species there is evidence that successful mating cannot occur until the male has attained dominance over the female. The functions of courtship behavior are related to these biological necessities. Courtship activities serve to establish or to strengthen the pair bond between a male and a female of the same species and to synchronize the sexual cycles of the members of such a pair. In some animals pairs may be formed a considerable time before actual mating occurs. Courtship displays are usually highly specific, and this helps to prevent the establishment of a lasting pair bond between members of different species. Some of the most spectacular courtship displays are found in those species in which the pair bond is of short duration. For example, in certain species of birds wherein the sexes meet only for the time involved in copulation (for example, prairie chickens, hummingbirds, and certain birds of paradise) the displays of the males involve elaborate postures, calls, and other activities for which special color patterns and structures have been evolved.

In many species of animals the males defend a "territory" and challenge with "threat displays" all members of their species which trespass. A rock may be a territory to a fish; an area of woodland or a few square feet on a rocky ledge may serve the same purpose for a bird. The "threat displays" of males on their territories elicit varying reactions from intruders of different sexes. A male intruder will either fight or flee; a receptive female will respond in a manner, varying with the species, which will reveal her sex and her degree of readiness to mate. Thus the initial phases of the male's courtship behavior often have a dual function: intimidation of rival males, and attraction of receptive females.

The functions of courtship behavior, then, are first to attract a mate and second to induce the mate to copulate. In some groups of animals which are able to detect sound the initial attraction of a mate is effected by an auditory stimulus. The chirping of crickets and the calls of frogs and toads are examples. The songs of male birds have a dual function. Primarily, bird song acts to advertise a male on his "territory" and actually aids in the defense of his territory against other males of the same species. The song also serves as an invitation to unmated females. In any one area the songs of the resident species of birds are highly specific and the females' response is very selective. Song thus acts to prevent or reduce

the probability that mixed pairs will be formed, and hence becomes an important isolating mechanism.

In the European locust, *Ephippiger ephippiger*, females which are ready to mate locate males by their "singing." Although females are attracted to invisible singing males from at least 30 feet away, they do not go to silent males even though the latter may be much closer. When males are silenced by having their wings glued together, they are unable to attract a single female.

The attraction of a mate by scent has been observed in butterflies and moths. In most species the females have special scent glands which produce highly specific odors. The receptor organs of the males are located in the antennae.

In the common garden snail, *Helix pomatia*, there is a lengthy courtship, culminating in the release of a small calcareous dart which is driven into the partner's body. Since this animal is hermaphroditic, the release of the dart mutually stimulates the partners to copulate.

Male fiddler crabs of the genus *Uca* attract the females by waving the large claw in a highly specific movement. The manner of waving also serves to warn off other males of the same species.

Courtship behavior in the three-spined stickleback, a small fish of the genus *Gasterosteus*, has been studied in great detail. The male settles on a "territory" which he defends against other male sticklebacks and in which he builds a nest. When a female with a swollen abdomen, indicating that she is ready to lay her eggs, appears within sight the male begins his courtship with a "zigzag dance." This consists of a series of up to 20 zigzag movements in rapid succession. The female reacts to the red color of the male and to his zigzag dance by swimming toward him. This in turn induces the male to swim quickly to the nest and the female follows. The male points his head at the nest entrance, thereby stimulating the female to enter. The male now begins to thrust his snout at her rump with a quick, rhythmic, quivering movement and the female responds by spawning her eggs into the nest. The presence of fresh eggs in the nest stimulates the male to fertilize them.

The jewel fish (*Hemichromis bimaculatus*) is well known to tropical fish culturists. During the breeding period the male defends a territory against all other fish which venture near the rock he has selected as a nest site. Other males and non gravid females flee before his attacks but the egg-laden female is attracted by the display movements of the male and stands her ground. Mutual displays ensue which involve "quivering" movements in a horizontal position and "head-standing" postures in a vertical plane. The head-standing position is the same as that taken when the egg masses are cleaned of algal or fungoid growths later on. These displays serve to bring the members of the pair into reproductive synchrony, and finally the female deposits her eggs on the rock chosen by the male and he fertilizes them.

In certain species of salamanders the males discharge their sperm cells in a small stump-shaped packet called a spermatophore, which they deposit on the ground or in the water. Courtship activities in these animals precede the discharge of the spermatophore and function both to stimulate the male to produce it and the female

to pick it up. In the marbled salamander (*Ambystoma opacum*), a chiefly nocturnal species, the senses of smell and touch are utilized in courtship. The males possess specialized glands on the head and at the base of the tail. The odor of the secretions of these glands, coupled with special movements and caresses by the male, attracts and stimulates the female and causes her to follow the male closely, sometimes for as long as an hour. The male eventually discharges a spermatophore and the female, if sufficiently stimulated by the courtship behavior of the male, picks it up in her cloaca.

Courtship behavior has been studied in birds to a greater extent than in most other groups of animals because the displays of birds are highly varied and easily observed. Displays tend to involve exaggerated, unusual movements during which peculiar adornments are thrust into prominence. Plumes, patches of bare skin, brightly colored areas of plumage, ruffs, crests, inflatable sacs, and other structures are utilized. The male common pigeon (*Columba livia*) of the city parks pursues a female with tail fanned and scraping the ground while he coos and bows. The display of the peacock is known to everyone.

Some of the most elaborate displays occur in those species which utilize a territory only as a mating station. Males of the prairie chicken (*Tympanuchus cupido*) of the Great Plains establish small territories on a communal "booming ground." Each male defends his few square yards of ground against the other males and awaits the arrival of a female. Females are attracted to the "booming ground" by the calls of the males, which can be heard far across the prairie. When a female arrives on the booming ground the males begin their full display. First a male makes a short run, stops, and stamps his feet rapidly. At the same time the brilliant orange air sacs on each side of the neck begin to inflate and the long feathers of the nape are erected. The tail is fanned and the fleshy orange "eyebrows" become prominent. The "booming" which immediately begins lasts about three seconds and consists of three hollow, low-pitched notes, "oo-loo-woo." Between periods of "booming" the male performs an elaborate bowing ceremony, during which he prostrates himself with outstretched wings and bill touching the ground. Following the booming and bowing of the male the female crouches and copulation follows.

The male Gould's manakin (*Manacus manacus*) of Panama is a small yellow and black species. The males clear a court approximately 20 by 30 inches on the forest floor, leaving only the bare earth. Courts of individual males are usually about 30 feet apart. In the breeding season the males spend most of the day at the court, leaving only to feed for short periods. When a female comes into the area the male begins his display. With the elongate feathers of the throat erected and thrown forward to form a projecting "beard" he calls "pee-you" with increasing volume and tempo as he hops rapidly from perch to perch. Suddenly he raises his wings and vibrates them rapidly, making a whirring sound as he calls "chee-poooh." He now enters the court and springs from side to side around the court, making a snapping sound with the wings and always alighting facing the spot from which he jumped. Sometimes a bird will press the tip of his beak into an upright stick and flutter like a moored

dirigible, or will alight in the court, head down and wings vibrating. The female is leaf-green in color and difficult for the human eye to detect, but the male manakins see her a long distance away. The female goes to the court of her choice, where the male begins to jump back and forth across the court. The female joins in the "dance" and the two birds leap rhythmically across the court, passing one another in mid-air. Finally they fly away together, actual mating taking place away from the court.

The males of the Brandt's cormorant (*Phalacrocorax penicillatus*) of the Pacific coast take up territorial stations on the breeding grounds. In their territories the males perform an elaborate "advertising display," one of the functions of which is to attract a female bird and induce her to pair. The "advertising display" is performed as follows: the male squats with the breast almost touching the substrate and the neck drawn back so that the nape rests on the back with the bill pointed upward. The tail is cocked and spread, and the head plumage is fluffed out. The gular (throat) pouch bulges and the brilliant blue color of the pouch is fully exhibited. The wings are lifted slightly from the back and slowly fluttered. This flutter phase of the display may last for as long as 25 seconds, then the wings are partly folded and the head thrust forward and downward in a hammer-like stroke. As many as 15 strokes may be repeated before the bird reverts to the flutter phase of the display and begins the cycle over again.

In many species of birds the lining of the mouth is brightly colored and is used in a type of display called ceremonial gaping. The climax of the courtship display of the red-breasted merganser (*Mergus serrator*) comes when the drake faces the duck and opens his beak to its fullest extent, revealing the brilliant red mouth lining. The European cormorant (*Phalacrocorax carbo*) displays the vivid yellow of its mouth lining as part of its courtship performance, while both male and female kittiwakes (*Rissa tridactyla*) crane their necks toward one another and scream with bills agape, revealing the lurid orange-red interior.

Some species of birds perform mutual displays during courtship, both members of the pair taking part. In the western grebe (*Aechmophorus occidentalis*) there are three types of mutual displays. In one the two birds swim side by side with necks arched, bills turned straight down, and their black crests spread. As they swim they sway their necks from side to side, touching them against their bodies. Sometimes this performance culminates in the "water glide" display, in which both birds suddenly stand upright as if running on the water, and with wings appressed tightly to their bodies, splash along the surface for 20 or 30 feet, dropping at last to the water and ending in a glide of 15 feet or more.

A third type of mutual display occurs more rarely. Both grebes dive and reappear with pieces of vegetation in their bills. Facing each other, they rise, treading water, with bodies half above the surface and necks stretched straight up. In this position, breast to breast, they slowly make three or four circles, then drop back to the water, flip the plant material from their beaks, and swim away.

The male Anna's hummingbird (*Calypte anna*) performs a spectacular display flight. First he towers upward until almost lost to sight, then

shoots vertically downward in a "power dive" at tremendous speed, suddenly altering his course at the bottom of the dive to describe an arc like a shallow "J." At the bottom of the arc a sharp, explosive note is produced by the force of the air stream on the modified outer tail feathers. He hovers a moment at the terminus of the arc and sings "zeele-zeele," then repeats the performance. This display may be directed toward a female, another male, or almost any other animal which ventures into the male's territory.

The remarkable performances of the various species of birds of paradise are probably the most elaborate courtship displays of any animal. The male king bird of paradise (*Cicinnurus regius*) begins his display with several squeaking notes, next he spreads his wings, flaps them, and, puffing out his silky-white lower feathers, bursts into a melodious warbling song. As he sings he displays his beautiful fanlike side plumes and spreads his short tail, pressing it close over his back so as to throw the long "tail-wires" over his head, while he gently sways his body from side to side. The spiral tips of the long "tail-wires" are bright green, and the swaying motion tosses them from one side to the other. The finale comes when he turns suddenly around and shows the fluffy white under tail coverts, then bends down on the perch and opens his mouth to reveal its light apple-green lining. A single drawn-out note is given, the tail is lowered, and the display is over.

COURTSHIP OF MILES STANDISH,

The, a narrative poem by H. W. Longfellow, based on a New England tradition, published in 1858. Priscilla archly asks, "Why don't you speak for yourself, John?" when John Alden urges the suit of his friend Miles Standish.

COURVILLE, town, Province of Quebec, Canada, in Quebec County, on the St. Lawrence River, about seven miles northeast of Quebec city, of which it is largely a residential suburb. Pop. (1951) 3,148.

COUSIN, kōō-zān', Jean, THE ELDER, French artist: b. Soucy, near Sens, 1490; d. Paris, 1560. He is generally regarded as the earliest French historical painter. He chiefly painted on glass, but his *Last Judgment*, painted on canvas for the convent of the Minims at Vincennes, is esteemed an excellent work. In 1540 he designed the festive decorations for the entry of Emperor Charles V at Paris. Noteworthy among his sculptured works are the tomb of Admiral Philippe de Chabot (Louvre) and the sculptures formerly in the chapel of Pagny (Burgundy). A large number of wood cuts have also been credited to him. He was the author of *Traité de perspective* (1560) and *Livre de portraicture* (1571).

His son, JEAN, THE YOUNGER, also an artist: b. Sens about 1522; d. Paris, 1590. He designed the glass windows and possibly the sculptures of the Castle of Fleurigny at Sens. The glasses in

the Church of Saint-Gervais, Paris, are also attributed to him. He painted five portraits of the Bouvyer family.

COUSIN, Victor, French philosopher: b. Paris, Nov. 28, 1792; d. Cannes, Jan. 12, 1867. He lectured at the Sorbonne during 1815-1817, and again from 1828 until his retirement in 1851. In 1830 he was made a councilor of state, created a peer of France, and appointed director of the École Normale; in 1840 he became minister of public instruction in the Cabinet of Louis Adolphe Thiers. He founded a school of eclectic philosophy, combining the doctrines of the Scottish school of Thomas Reid and Dugald Stewart, based on sensation, with those of Friedrich W. J. von Schelling and Georg W. F. Hegel, which rest on the opposite principle of idealism or intuition. Although he was not an original thinker he possessed in a high degree the faculty of clear exposition, and for that reason his lectures and his writings enjoyed a great popularity. He rendered a memorable service both to philosophy and literature by his translation of *Plato* (1840). Besides his *Fragments philosophiques* (1826) and other works on that theme, he is the author of a few biographical sketches, mostly of characters related to the spiritual and intellectual movements of the 17th century, as *Jacqueline Pascal*; *Mme. de Longueville*; *Mme. de Hauteclerc*; *French Society in the 17th Century*. As a lecturer and philosophical writer Cousin was distinguished by a rare combination of eloquence, enthusiasm, and, as already stated, clearness of exposition. He possessed a beauty of style such as no modern or ancient philosopher excepting Plato has equaled. He rendered a very valuable service to his native land in the part he took in the organization of primary instruction. In 1831 he visited Germany to study educational methods there, and the *Rapport sur l'Etat de l'Instruction Publique* published on his return had powerful influence on subsequent legislation.

COUSIN-MONTAUBAN, kōō-zān' mōn-tō-bān', Charles Guillaume Marie Apollinaire Antoine, COMTE DE PALIKAO, French military officer and statesman: b. Paris, June 24, 1796; d. Versailles, Jan. 8, 1878. In 1847, while serving with the cavalry in Algeria, he captured Abd-el-Kader, leader of the Arab revolt, and for this success he was promoted general of division. He commanded the French forces in the joint Franco-British expedition in China during 1859-1860, occupying the capital city of Peking (Peiping). Napoleon III created him comte de Palikao in 1862. With outbreak of the Franco-Prussian War in 1870 he was appointed war minister, and for 24 days during August-September he was president of the council, as head of the government reorganizing and strengthening the armed forces. After Emperor Napoleon III surrendered at Sedan on September 2 he was offered the dictatorship of France, but refused; and with the fall of his government he took refuge in Belgium. He wrote *Un Ministère de la guerre de vingt-quatre jours* (1871).

COUSINS, kūz'nz, Samuel, English mezzotint engraver: b. Exeter, Devonshire, May 9, 1801; d. London, May 7, 1887. He first came into public notice by his mezzotint engravings of the works of Sir Thomas Lawrence, notably *Lady Acland and her Children* in 1826. These were

Catholicism, which it denounced. It was again subscribed to in 1590 and 1596.

After the union of the crowns of Scotland and England (1603), because the Stuarts favored the Episcopal Church, the dangers which threatened Presbyterianism brought its followers in Scotland to a closer union. And when, in 1637, Charles I tried to force the Church of Scotland to accept a new liturgy modeled after the English, disturbances arose which ended in the forming of a new covenant the following year. This was called the National Covenant (1638). The subscription of it began in the Grayfriars' Church, Edinburgh, on Feb. 28, 1638. Copies were circulated throughout the country for general signature, many of which are still in existence. The National Covenant, with the confession of faith which it embodied, was ratified by the General Assembly at Glasgow on Nov. 21, 1638, and by the Scottish Parliament in 1640. In 1642 the English Parliament applied to the Scots for aid in the civil war taking place in the reign of Charles I, and the application was pressed more earnestly in the following year. The Covenanters, who were then masters of Scotland, demanded that the English Parliament should take the covenant and assimilate the doctrine and discipline of the churches of the two nations. In consequence of this stipulation, on Sept. 25, 1643, both houses of Parliament met at Saint Margaret's Church, Westminster, along with the Assembly of Divines and the Scottish commissioners, to take the Solemn League and Covenant, which had been modified by the General Assembly. After prayers and sermons, all present held up their hands in testimony of assent to it; and afterward, in their several houses, they subscribed it on a Parliament roll. The House of Commons ordered it to be taken by all persons in their respective parishes on the next Lord's Day.

Both covenants were signed by Charles II on his landing in Scotland in 1650, and again at his coronation at Scone on Jan. 1, 1651. The Covenanters were now the supreme power in Scotland, but their supremacy was undermined by their defeat by Oliver Cromwell at Dunbar in 1650, and vanished when Charles II was restored in 1660.

In 1662, episcopacy was restored and the covenant was renounced by act of Parliament, in both England and Scotland. Oppressive measures were inaugurated against the Covenanters who, outraged, took up arms in 1665 in defense of the Presbyterian form of church government. The Presbyterian ministers who refused to acknowledge the bishops were ejected from their parishes and drew around them crowds of their people on the hillsides and in secret places, to attend their ministrations. These meetings, called "conventicles," were denounced as seditious, and to frequent them, or to hold communication with those frequenting them, was forbidden on pain of death. The severity with which the recusants were treated provoked them to take up arms in defense of their opinions. The first outbreaks took place in the hill country on the borders of Ayr and Lanark shires. At Drumclog, a farm near Loudon Hill, a conventicle was attacked in 1679 by a body of dragoons under Graham of Claverhouse, but the Covenanters were successful in defeating their assailants. This defeat, and the murder of Archbishop James Sharp on Magus Moor in

1679, alarmed the government which sent a large body of troops to put down the insurgents, who had increased in number rapidly. The two armies met at Bothwell Bridge, where the Covenanters were totally defeated (June 22, 1679).

In consequence of the rebellious protests against Charles II, called the Sanquhar Declaration, put forth in 1680 by Richard Cameron, David Cargill, and others, as representing the more irreconcilable of the Covenanters (known as Cameronians), and a subsequent proclamation engineered by James Renwick in 1684, the government proceeded to more severe measures. An oath was required of all who would free themselves of suspicion of complicity with the Covenanters, and the dragoons sent out to hunt down the rebels were empowered to kill anyone who refused to take the oath. During this "killing-time," as it was called, the sufferings of the Covenanters were extreme. But notwithstanding the great number who were put to death, their fanatic spirit seemed only to grow stronger. Even after the accession of William III and the settlement of the revolution of 1688 which restored the Presbyterian Church government (without renewal of the covenants, however), some of the extreme Covenanters refused to acknowledge William because of his acceptance of episcopacy in England; and these formed the earliest dissenting sect in Scotland, calling themselves Covenanters or Reformed Presbyterians.

COVENT GARDEN. Originally the garden of the abbot of Westminster, the name being corrupted from Convent Garden, it is a spacious square north of the Strand in London, celebrated as a great market for fruit, vegetables, and flowers. The square was formed about 1631 from plans drawn by Inigo Jones, and has an arcade or piazza on the north and northeast side and Tavistock Row on the south. In the 17th century Covent Garden was a very fashionable quarter. The now-famous market appears to have originated about 1656 in a few wooden sheds and stalls. The first Covent Garden Theater was erected there in 1733; it was destroyed by fire in 1808, rebuilt from a design by Sir Robert Smirke in 1809, and burned again in 1856. The present opera house was built in 1858, and was used as a dance hall for the armed forces in World War II.

COVENTRY, kōv'ən-trī, town, Conn., located in Tolland County about 30 miles southeast of Hartford, on the Willimantic River. It is served by the New York, New Haven and Hartford Railroad, the Central Vermont Railway, and buses of the New England Transportation Company. Coventry is an agricultural community, a large part of its working population finding employment in nearby industrial cities. Lake Wangumbaug is within the town. Coventry was named and incorporated in October 1712, and has an area of 25,509 acres. It is the birthplace of Nathan Hale. Pop. (1940) 2,102; (1950) 4,035 (prelim.).

COVENTRY, city and county borough, England, in Warwickshire, about 85 miles northwest of London, on the Sherbourne. It became a civic corporation in 1344 and a county in 1451; was incorporated with the county of Warwick in 1842; and became a county borough in 1888. The borough sends three members to Parliament. One of the oldest cities in England, a Benedictine monastery was founded there in 1044 by Earl Leofric and Lady Godiva (q.v.), his wife, with whose famous legend Coventry is associated. Many of the buildings, including the cathedral, were destroyed by Henry VIII; their remains may be seen near the present-day Holy Trinity Church. Parliaments were convened there by the earlier monarchs of England, several of whom occasionally resided in the city. Pageants and processions were popular in former times, and the Coventry Fair, held during White Week, was authorized by Henry VIII as an eight-day festival. The dukes of Norfolk and Hereford met here to fight on Gosford Green, and the incident was used by Shakespeare in *Richard II*. The phrase, "to send to Coventry" (meaning to refuse to associate with someone) is believed to have come from the custom of Birmingham people's sending their political prisoners to Coventry.

Once noted for its many fine churches—among them the 14th-century St. Michael's Cathedral, an excellent example of Perpendicular architecture; the cruciform Holy Trinity Church; and Christ Church—much of Coventry was blasted into ruins in German bombing raids of Nov. 14-15, 1940, and April 8, 1941. Many interesting architectural remains survived, although the cathedral (except for its spire), Christ Church, the women's almshouses (16th century), the Central Library, King Henry VII's School, and other public buildings were destroyed. St. Mary's Hall (14th century), once a craft guild center, was severely damaged.

Formerly famous for its ribbons, woollens, silk-dyeing, broadcloths, and caps, modern Coventry's manufactures include bicycles, automobiles, airplanes and engines, telegraph and telephone equipment, machine tools, naval stores, munitions, and rayon goods. Before the advent of British nationalization, the city owned its gas, electrical, and water plants. It has an excellent sewerage system. There are good road, rail, and canal communications, and an airport was built in 1936. Pop. (1951) 258,211.

COVENTRY, township, R. I., located in Kent County, and served by the New York, New Haven and Hartford Railroad. It has an area of 62 square miles and is made up of several small villages; those in the northeastern and central part of Coventry are chiefly industrial; those in the northwest and southwest are agricultural. Prior to 1741, Coventry was a part of Warwick; in that year it was incorporated as a separate township. Its center of government is in the village of Washington. Pop. (1940) 6,998; (1950) 9,852 (prelim.).

COVENTRY PLAYS. A series of 42 early English miracle plays, related to the old English morality and mystery plays, containing the New Testament story. Coventry was famous in the period 1392 to 1589 for the performance of its Corpus Christi Day plays by the Gray Friars. The Coventry plays were published in

a volume by the Shakespeare Society in 1841, under such titles as *The Creation, The Fall of Man, The Birth of Christ, The Resurrection*, and *The Ascension*. See also MIRACLE PLAYS.

COVERDALE, kŭv'ēr-dāl, Miles, English bishop and reformer: b. probably at Coverdale, Yorkshire, 1488; d. Feb. 1568 (buried in London, Feb. 19, 1568). He was educated at Cambridge, entered the convent of the Augustinian friars, was ordained a priest at Norwich in 1514, and entered the convent of Austin friars at Cambridge where he came under the influence of Robert Barnes who became prior about 1523. He also became a friend of Thomas More and Thomas Cromwell at this time. Some years later he was led to embrace and preach the reformed doctrines and, having gone abroad, adopted Lutheranism and is said by Foxe to have assisted Tyndale in translating the Pentateuch. In 1535 his own translation of the Scriptures appeared with a dedication to Henry VIII, this being the first printed English version of the entire Bible. No publisher's name appears on the imperfect copies which now exist, but it was probably printed by Nicolson in folio and quarto in 1537, and by Froschover at Zurich in 1550. It is possible that Jacob van Meteren was its promoter, and that he engaged Coverdale to do the translation for him. In 1538 he was engaged by Cromwell to superintend the printing in Paris of a revised English version of the Bible; and when the work was halted by the French ecclesiastical authorities, the presses and type were brought to England in 1539, and there the so-called Great Bible, with a preface by Archbishop Cranmer, was printed by Grafton and Whitchurch in 1540. After the execution of Cromwell (1540), Coverdale went to Germany where he became a Lutheran minister and taught school in Bavaria. Returning to England in 1548, he was made almoner to Queen Catherine Parr, and in the following year assisted Whitchurch in the second volume of the *Paraphrases of Erasmus*. In 1551, during the reign of Edward VI, he was appointed bishop of Exeter, but was ejected on the accession of Mary Tudor and was thrown into prison. Two years later he was liberated and proceeded first to Denmark and subsequently to Geneva where he assisted in preparing the Geneva Bible (published in 1560). After the accession of Elizabeth, he returned to England (1559) and was rector of Saint Magnus, London Bridge, until his resignation in 1566.

His writings are numerous; biographies may be found in the Parker Society editions of Coverdale's pieces, an index to which may be found in Gough's *General Index to the Parker Society*. Consult also his biography in the *Dictionary of National Biography* (Vol. 12); his writings and letters, edited by George Pearson (2 vols., 1844-1846); and Guppy, Henry, *Miles Coverdale and the English Bible* (Manchester University Press 1935).

COVERLEY, kŭv'ēr-lī, Sir Roger de. A literary character introduced by Sir Richard Steele in the *Spectator* in 1711 as a Worcestershire gentleman whose great-grandfather had invented "the famous country dance which is called after him." He was further portrayed by Joseph Addison as a lovable, generous, somewhat eccentric figure in 20 Sir Roger de Coverley papers in the *Spectator* (1711-1712), and to a lesser extent by Addison's cousin, Eustace Budgell. The old English country dance resembled its more modern American form, the Virginia reel.

COVILHA, kō-vê-lyǎn', commune, Portugal, in the modern district of Castelo Branco, and in the province of Biera Baixa, on the south-east slope of the Serra da Estrella, some 50 miles east of Coimbra. In the neighborhood there are noted sulphurous baths, and the town has recently become a skiing center. Covilhã contains dyeworks and important cloth factories. Pop. (1940) 19,213.

COVILLE, kō'vīl, **Frederick Vernon**, American botanist: b. Preston, N. Y., March 23, 1867; d. Washington, D.C., Jan. 9, 1937. He was educated at Cornell University and was instructor in Botany there (1887-1888) and assistant botanist in the United States Department of Agriculture (1888-1893). From the last named year he was chief botanist of that department, as well as curator of the United States National Herbarium. He was instrumental in founding the Desert Botanical Laboratory in Tucson, Ariz. He published *Botany of the Death Valley Expedition* (1893); *Experiments in Blueberry Culture* (1910); and many other papers relating to systematic, geographic, and economic botany.

COVINGTON, kŭ'ing-tŭn, city, Georgia, and Newton County seat, altitude 747 feet, on the Georgia and the Central of Georgia railroads, 32 miles east-southeast of Atlanta. It has twine, fabric, lumber, and cotton mills, and manufactures fertilizer and trousers. Covington was incorporated as a town in 1822 and as a city in 1854. The water supply is municipally owned and the government is by mayor and council. Pop. (1950) 5,192.

COVINGTON, city, Kentucky, and seat of Kenton County, altitude 513 feet, on the Ohio River opposite Cincinnati (with which it is connected by two bridges, one of them a suspension bridge opened in 1866 and designed by John A. Roebling) and at the mouth of Licking River, opposite Newport, also connected by bridges to Covington. It is served by the Chesapeake and Ohio, Louisville and Nashville, and Cincinnati Southern railroads, and three federal and two state highways. It is an important shipping point by rail, water, and highway for Kentucky products, notably thoroughbred horses and other livestock, and is the second most important city in Kentucky. Occupying an area of about 5¼ square miles in a beautiful plain partly surrounded by hills, Covington has fine, wide streets, handsome residences (many Cincinnati business men live here), a public library, courthouse and city hall, Latonia Race Track, and Devou Park (550 acres). Charitable institutions include a hospital for contagious diseases, Catholic and Protestant orphan asylums, and a home for aged women. Covington is the see of a Catholic bishop, and St. Mary's Cathedral, a replica of Notre Dame of Paris and noted for its stained glass windows, is one of the finest ecclesiastical structures in the state. The city is the seat of Villa Madonna College (1921; coeducational), of the Northern Kentucky State Vocational School, and of other private institutions.

It has important manufactures of X-ray equipment, drilling machines, lathes, cigars, tobacco, prison equipment, iron, textiles, lumber, paper bags, brass and bronze products, signs, and other varied products.

Settled about 1812 as a ferry crossing with a tavern, it was platted three years later, chartered as a city in 1834, and is now governed by a city manager with mayor and commissioners. The water supply system is municipally owned and is drawn from the Ohio River about 13 miles above the city. Pop. (1930) 65,252; (1940) 62,018; (1950) 64,452.

COVINGTON, town, Louisiana, seat of St. Tammany Parish, 37 miles north of New Orleans, situated on the Bogue Falaya, near Lake Pontchartrain. Mainly an agricultural town with strawberries, oranges, and cotton being produced in the surrounding region, it manufactures charcoal, tung oil, and wood preservatives. It is a year round resort, with excellent hunting and fishing afforded.

The town was settled as early as 1769, incorporated in 1813, and has been parish seat since 1828. It is governed by a mayor and council. Pop. (1950) 5,113.

COVINGTON, town, Tennessee, and Tipton County seat, altitude 311 feet, on the Illinois Central Railroad, 38 miles northeast of Memphis. It is in a cotton-growing region, and has textile industries and cottonseed factories. The town has a public library. It was settled about 1800 and incorporated in 1833. Government is by mayor and council. Pop. (1950) 4,379.

COVINGTON, town, Virginia, Alleghany County seat, altitude 1,245 feet, on Jackson River and the Chesapeake and Ohio Railroad, situated in the midst of the Allegheny Mountains, 35 miles north of Roanoke. The West Virginia Pulp and Paper Company has a large plant here; other industries are rayon and textiles. There are coal and iron fields nearby and some limestone quarrying. The town was incorporated in 1873 and has a town manager. Its water system is municipally owned. Pop. (1950) 5,860.

COVODE, John, American congressman: b. Westmoreland County, Pa., March 18, 1808; d. Jan. 11, 1871. He was a farmer's son of Dutch blood and became a manufacturer and railroad owner. He entered public life as a Whig, served two terms in the state legislature, was sent to Congress in 1854 by the anti-Masons, and was re-elected in 1856 as a Republican, serving by regular re-elections until 1863. In 1860 he was appointed chairman of the special committee to investigate President James Buchanan's conduct in forcing through the Lecompton Bill (see title below, and **LECOMPTON CONSTITUTION**), and his report was valuable ammunition for the Republican Party. He was a member of the committee on the conduct of the war, and after Andrew Johnson's accession he was sent to the South to aid in that president's reconstruction policy, but was recalled for lack of sympathy with it. In 1867 he was again elected to Congress, and was a strong opponent of Johnson, introducing the resolution of impeachment against the president into the House of Representatives.

COVODE INVESTIGATION, 1860. President Buchanan, in the struggle to have Congress validate the Lecompton constitution (q.v.), was urged by the party organs to save the unity of the Democratic party, which was menaced with irremediable division, by using

the patronage at his disposal to bring the hesitating members into the ranks. In the debates at the opening of the 36th Congress, 1859-1860, two anti-Lecompton Democrats alleged that he had attempted to use corrupt influence with them. On March 5, 1860, John Covode moved the appointment of a committee to inquire whether the president or any other official had attempted, by money, patronage, or other improper means, to influence legislation or the execution of the laws. Despite Democratic objection that only insinuations and no specific charges were made, the rules were suspended by 117 to 45, the resolution was adopted, and an investigating committee of five was appointed, with Covode at the head. Buchanan sent a message of protest, March 28, objecting on the ground that the president could be indicted only by impeachment, that this was an indictment, and that such a method was inconsistent with the dignity of the office. The protest was declared unfounded by 88 to 40. On June 16, the committee reported, the Republican members declaring that the mass of evidence collected was proof of corrupt use of patronage, and Covode later alleged that they found also bribery, as evidenced by bankbooks. The Democratic members declared the allegations unsupported. No action was recommended to the House by the majority report, and none was taken. On June 22, Buchanan sent a second message protesting against the rejection of his first and saying that on such views no man of honor and principle could accept the presidency.

Consult U.S. Congress, *House Report 648* (Washington 1860); Buchanan, James, *Mr. Buchanan's Administration on the Eve of the Rebellion* (New York 1866); Curtis, G. T., *The Life of James Buchanan*, 2 vols. (New York 1883).

COW, the mature female of such bovines as domestic cattle, yak, buffalo, bison, most Old World antelopes; also the mature female of other large terrestrial herbivores such as the giraffe, elephant, rhinoceros, tapir, and hippopotamus. The term cow has been established for the mature female of all cetaceans (whales, dolphins, porpoises), all pinnipeds (seals, sea lions, walruses), and all sirenians (dugongs, manatees or sea cows). The term cow is used interchangeably with the term doe for the mature female of the largest members of the deer family (reindeer, caribou, moose, elk, wapiti). The term has been extended to certain nonmammalian animals kept as cattle for food, such as the terrapin, or tended and "milked," as is the plant aphid by ants.

COW LILY. See NUPHAR.

COW PARSNIP, a genus (*Heracleum*) of about 60 species of tall biennial or perennial herbs of northern temperate distribution with large compound leaves, broad umbels, and white or purplish flowers, belonging to the parsley family (Umbelliferae). Masterwort (*H. lanatum*), a commonly used forage plant, is a tall (nine feet) woolly perennial with ternate leaves, found in wet meadows in eastern Asia and in North America, where its southern range is from Georgia to Arizona. It is doubtful that it is poisonous to cattle. Another species, eltrof or helitrot, hogweed (*H. sphondylium*) is like masterwort in habit and structure. Pliny attributed great medicinal importance to the genus in the 1st century A.D. and dedicated it to Hercules, who used it in medicine.

COW PILOT. See SERGEANT MAJOR.

COW PLANT, ^{Australian}, the common name of a woody climbing member (*Gymnocma sylvestre*) of the milkweed family (Asclepiadaceae) found in the forests of Queensland, India, and tropical Africa. The root, as well as the rest of the plant, contains a milky juice of bitter, even saltish, taste. This is due to a glucoside, gymemic acid, which on chewing parts of the plant destroys the sense of taste for sweetness and bitterness. East Indians on a sugar-free diabetic diet chew the leaves of this plant. The root is applied locally and internally as a remedy for snake bite. The Singalese use the sap of another Asiatic species (*G. lactiferum*) as a substitute for cow's milk. The small yellow flowers lack a corolla, leaving the filaments exposed, hence the generic name. In the United States, cow plant is sometimes applied to the great laurel (*Rhododendron maximum*).

COW TREE, a common name applied to various plants yielding copious latex used in place of milk. Half a dozen species of the genus *Couma* of the dogbane family (Apocynaceae) are regarded as cow trees, as is *Manilkara Fluberi* of the sapote family (Sapotaceae), found in the lower Amazon region, where it attracted the attention of the famous traveler Richard Spruce in 1849. Cow tree is mostly used for the cow breadnut tree (*Brosimum utile*) of the mulberry family (Moraceae). It is a large tree growing to a height of 70 feet, native in tropical America and widely known for its agreeable and wholesome latex used as food by natives. Another species, the breadnut tree of Jamaica (*B. allicastrum*), is native in Yucatán, Central America, and the West Indies. It grows to 100 feet in height and has large leathery leaves up to seven inches long. This species is grown in the tropics for its leaves and young shoots, used as fodder, and chestnut-sized seeds (breadnuts), which are roasted or boiled before they are eaten.

COWAGE. See COWHAGE.

COWANSVILLE, kou'änz-vīl, town, Province of Quebec, Canada, situated on the Yamaska River, 25 miles east-southeast of St Jean. Industries include furniture manufacturing, woodworking, and silk and cotton milling. Pop. (1951) 4,431.

COWARD, kou'ērd, Noel, English playwright, actor, and composer: b. Teddington, England, Dec. 16, 1899. Educated privately, he made his stage debut at the age of 11, appearing later in repertory and provincial theaters. He first showed his versatility in *London Calling*, which appeared at the close of World War I, and for which he wrote the book, music, and lyrics, and played the leading role. His other plays, usually reflecting some aspect of the contemporary scene, include *The Vortex* (1925), his first critical success; *Private Lives* (1930); *Design for Living* (1932); *Tonight at 8:30* (1936); *Blithe Spirit* (1941); *Relative Values* (1951); and *Caligula* (1951), the deeply patriotic play which also was made into a successful film. His other important films have included *In Which We Serve* (1942), *This Happy Breed* (1944), and *Brief Encounter* (1945). He has written a great number of popular songs, both sentimental

and satirical. His autobiography, *Present Indicative*, appeared in 1937 and he is also the author of *To Step Aside* (1939), *Middle East Diary* (1945), and *Star Quality* (1951).

COWBANE or **WATER DROPWORT**, a poisonous erect American herb (*Oxypolis rigidior*) of the parsley family (Umbelliferae) found in bogs, swamps, and wet woods in the eastern and southern United States. The name cowbane is also applied to water hemlock (q.v.), another member of the same family.

COWBERRY, a name sometimes applied to the marsh fivefinger (*Potentilla palustris*) of the rose family (Rosaceae). A species about two feet high with woody stems rooting in water or marsh and purple flowers, found in North America (Alaska to Greenland, south to New Jersey, Ohio, Illinois, Iowa, and west to California) and in northern Eurasia. The name cowberry is also used for the mountain cranberry or rock cranberry (*Vaccinium vitis-idaea* var. *minus*) of the heath family (Ericaceae), a creeping evergreen with red, slightly bitter berries, found in subarctic North America to New England, Minnesota, and British Columbia, but smaller than the typical European species.

COWBIRD, any of seven species of American birds of the family Icteridae, so called because they walk about among cows and buffaloes to secure insects disturbed by the grazing animals. In most of these species the female cowbird builds no nest and lays its eggs in the nests of other birds, which incubate the eggs and rear the young cowbirds. Best known is the brown-headed cowbird (*Molothrus ater*), found over most of North America. The male, some eight inches long, is shiny black with a brown head; the smaller female is dark gray and brown. The female cowbird is very adept at finding the nests of sparrows, vireos, warblers, and other small birds. Early in the morning she furtively enters the nest of her victim and lays one of her eggs, selecting a different nest for each of her eggs, and sometimes several female cowbirds lay in the same nest. Most small birds do not object to the cowbird's eggs, but some species desert their nest or, in the case of the yellow warbler, build a second nest on top of the first one, thus burying the cowbird egg (along with some of its own) in the floor of the nest. The rightful young of the nest often starve, for the young cowbird, having a more voracious appetite and a faster rate of growth, deprives them of their food. The other species of cowbirds are found chiefly in the American tropics. The giant cowbird (*Psomocolax*) lays its eggs in the long hanging nests of the tropical orioles known as oropendolas. The latter try to drive away the cowbird, but she eventually sneaks into the nest and lays one of her eggs.

Consult Friedman, Herbert, *The Cowbirds* (Springfield, Ill., 1929).

DEAN AMADON,
Associate Curator, Department of Birds, The
American Museum of Natural History.

COWBOYS, in the American Revolution, a band of American Tories who infested the neutral ground of Westchester County, N. Y., robbed Whigs and Loyalists, and made a specialty of stealing cattle. A similar band of marauders

on the British side received the name of Skinners.

The word cowboys is now used to designate the men who have charge of the cattle on the vast ranges in the west and southwest of the United States. A number of them were enlisted in two regiments of cavalry for the war with Spain and, under the popular name of Rough Riders, greatly distinguished themselves in the early part of the campaign against Santiago in Cuba.

COWDENBEATH, kou-d'n-bèth', burgh, Fifeshire, Scotland. About 18 miles northwest of Edinburgh, it is an important mining center. Here the Solemn League and Covenant was drafted about 1642. Pop. (1951) 13,153.

COWELL, kov'el, **Edward Byles**, English Sanskrit scholar: b. Ipswich, England, Jan. 23, 1826; d. Cambridge, Feb. 9, 1903. He was educated at Oxford and was for some years principal of the Sanskrit College, Calcutta, India. From 1867 he was professor at Cambridge University and was ranked as the foremost English Orientalist of his day. His association with Edward Fitzgerald, the translator of Omar Khayyám, made him an important figure in English literature. He published a great number of works in both Sanskrit and English, and translated many religious works from Sanskrit into English. His *Life and Letters* were edited by his relative George Cowell (Oxford 1904).

COWEN, kou'en, **SIR Frederic Hymen**, English composer and conductor: b. Kingston, Jamaica, B. W. I., Jan. 29, 1852; d. London, England, Oct. 6, 1935. He was brought to England at an early age and studied music under Sir Julius Benedict and Sir John Goss. He published his first composition when he was six years old. From 1888 to 1892, and from 1900 to 1907, he conducted the Philharmonic Society, holding many musical posts in the interim and subsequently. His best-known works include *Pauline*, an opera (1876); six symphonies, the chief being No. 3 (Scandinavian, 1880), No. 4 (Welsh, 1884), and No. 6 (Idyllic, 1897); the cantatas, *The Corsair* (1876), and *The Sleeping Beauty* (1885); and four English dances (1881). He composed over 300 songs, duets, piano pieces, and oratorios. In 1911 he was knighted and in 1913 he published an informal autobiography, *My Art and My Friends*.

COWEN, **Joseph**, English statesman and journalist: b. Blaydon-on-Tyne, England, July 9, 1831; d. Newcastle-upon-Tyne, Feb. 18, 1900. Educated at Edinburgh University, he became a passionate foe of oppression at an early age. His close ties with Giuseppe Mazzini, Lajos Kossuth, Aleksandr Ivanovich Herzen, and Giuseppe Garibaldi, as well as his outspoken support of the Chartists and the Irish Nationalists, brought him into opposition with most of the leading English political figures of the day. In 1886 he retired from Parliament, where he had served in the House of Commons as a Liberal member from 1873, to devote himself to writing and speaking. He was renowned as an orator, speaking strongly for Home Rule for Ireland before that cause was supported by Cecil John Rhodes and William Ewart Gladstone. Through his newspaper the Newcastle *Daily Chronicle*, and his monthly *Northern Tribune*, he wielded strong

influence in northern England for the causes which he so uncompromisingly supported.

COWES, kouz, seaport, England, located on the north coast of the Isle of Wight, 10 miles west-southwest of Portsmouth. The Medina River separates East Cowes from West Cowes. In 1540 Henry VIII erected here a castle which since 1856 has been the headquarters of the Royal Yacht Squadron. Outside Cowes, which is mainly a resort, is Osborne House, long a favorite residence of Queen Victoria. Pop. (1951) 17,916.

COWHAGE, kou'ij, **COUHAGE**, **COW-AGE**, or **COWITCH**, a plant (*Stizolobium pruritum*) belonging to the pea family (Papilionaceae). It is a twining annual with large racemes of dark-colored flowers, which in India appear in the rainy season. The pod, shaped like the letter *s*, is covered with delicate bristlelike spines, which are easily detached and, sticking in the skin, produce an intolerable itching. In India these spines are mixed with sirup and used as a vermifuge, the spines acting mechanically. When young, the pods are cooked and eaten like string beans.

COWHIDE. See **LEATHER AND SHOE TRADE TECHNICAL TERMS—Cowhide**.

COWL, koul, **Jane** (nee **COWLES**), American actress: b. Boston, Mass., Dec. 14, 1884; d. Santa Monica, Calif., June 22, 1950. After studying at Columbia University she made her Broadway stage debut in *Sweet Kitty Bellairs* (1903). Among the plays in which she starred were *Within the Law*, *Common Clay*, *Romeo and Juliet*, *The Road to Rome*, *Rain From Heaven*, *Old Acquaintance*, and *Camille*. She was also co-author of, and appeared in, *Daybreak*, *Information Please*, *Smilin' Through*, and *Lilac Time*. A great actress, she was called by the critics of her time the most beautiful woman on the American stage.

• **COWLES**, kôlz, **Henry Chandler**, American botanist: b. Kensington, Conn., Feb. 27, 1869; d. Chicago, Ill., Sept. 12, 1939. A graduate of Oberlin College, he received his doctorate in philosophy from the University of Chicago in 1898 and taught there from 1902 until 1934. He wrote *Plant Societies of Chicago* (1901) and *Textbook of Plant Ecology* (1911) and was editor of the *Botanical Gazette* (1925–1934).

COWLEY, kou'li, **Abraham**, English poet: b. London, England, 1618; d. Chertsey, Surrey, July 28, 1667. He so early imbibed a taste for poetry that in 1633, while yet at school, he published a collection of verses, entitled *Poetical Blossoms*. In 1637 he was elected a scholar of Trinity College, Cambridge, where he soon obtained a great literary distinction, and published in 1638 a pastoral comedy, entitled *Love's Riddle*, and another in Latin, called *Naufragium Jocularé*, acted before the university by the members of Trinity College. He was ejected from Cambridge as a Royalist in 1644 and went to St. John's College, Oxford, where he published a satirical poem entitled the *Puritan and the Papist*. He engaged actively in the royal cause, and when the queen was obliged to quit England, Cowley accompanied her. In 1656 he returned to Eng-

land, where he published an edition of his poems, containing *Miscellanies*, *The Mistress*, *Pindarique Odes*, and the never-finished epic, *Davidis* (on the history of King David). He again visited France, and resumed his functions of agent in the royal cause on the death of Oliver Cromwell. At the Restoration he returned with the other Royalists. By the interest of the duke of Buckingham and the earl of St. Albans he obtained the lease of a farm at Chertsey, whither he retired in 1665. In 1660 Cowley took part in founding the Royal Society; in 1661 he published *A Proposition for the Advancement of Experimental Philosophy*; and *Vision Concerning . . . Cromwell the Wicked . . .*, which is one of the best of his prose works. He published two books of a Latin poem on plants in 1662; he afterward added four more books, and the whole, together with other pieces, was published in 1678 under the title of *Poemata Latina*. A poem *On the Civil War* appeared in 1679; his *Select Works* were published in 1772.

Cowley was extremely popular in his day, and his style, both in prose and verse, has been highly commended by critics; but his poems have failed to maintain their earlier popularity. The wit for which they once were celebrated has become obsolete, and he is now little read; but Charles Lamb spoke highly of him as a poet and William Hazlitt praised him as a prose writer. Good modern editions of his works are *The Complete Works in Verse and Prose of Abraham Cowley*, ed. by A. B. Grossart, 2 vols. (Edinburgh 1881), and *The English Writings of Abraham Cowley*, ed. by A. R. Waller, 2 vols. (Cambridge 1905–1906).

Consult Nethercot, A. H., *Abraham Cowley* (Oxford 1931).

COWLEY, Hannah (nee **PARKHOUSE**), English poet and dramatist: b. Tiverton, Devonshire, England, 1743; d. there, March 11, 1809. Challenged, after her remark at a tedious play that she could do better, she finished *The Runaway* in a fortnight; it was produced in 1776 by David Garrick and became an instant success. Of her many subsequent successes the best known are *The Belle's Stratagem* (1782), *A Bold Stroke for a Husband* (1783), *More Ways Than One* (1784), and *The Town Before You* (1795). As one of the Della Cruscan (q.v.) she contributed verse to the *World*; a great deal of this was of such a sentimental nature that her pseudonym, Anna Matilda, has become a byword for mawkishly emotional writing.

COWLEY, Malcolm, American writer and editor: b. Belsano, Pa., Aug. 24, 1898. His first book, *Blue Juanita*, a collection of verse, was published in 1929, followed by *Exile's Return* (1934) and *The Dry Season* (1941). He was literary editor of the *New Republic* (1929–1944) and has been a contributor to numerous periodicals. His translations from the French include Paul Valéry's *Variety* (1926) and André Gide's *Imaginary Interviews* (1944). He is the editor of *The Portable Hemingway* (1944), *The Portable Faulkner* (1946), *The Portable Hawthorne* (1948), *The Complete Whitman* (1948), *The Stories of F. Scott Fitzgerald* (1951).

COWLEY FATHERS. See **ORDERS, RELIGIOUS—Anglican Orders** (Saint John the Evangelist, Society of).

COWPEA, kou'pé, an annual plant (*Vigna sinensis*) of the family Leguminosae, native originally to central Africa and introduced into the American colonies in the early 18th century. In appearance it resembles garden and field beans, since it produces trifoliate leaves and bears its seeds in long, slender, beanlike pods. Because the plants are very sensitive to frost, in the United States they are grown only in the South. With the rise of the soybean, with which it competes, the cowpea has declined in importance.

Thirteen states are responsible for most of the cowpea acreage in the United States. In 1953 these states grew an estimated 318,000 acres for peas, 254,000 acres for hay, and 467,000 acres for pasture or plowing under to enrich the soil. The total acreage of 1,039,000 is small when compared with the total United States soybean acreage of 16,510,000 for the same year. Several Southern states prefer the cowpea to the soybean, however, and grow considerably greater acreages of the former. The principal cowpea-producing states are Texas, South Carolina, Georgia, North Carolina, Oklahoma, Mississippi, and Alabama.

The cowpea plant has what botanists call an indeterminate type of growth, meaning that it continues to grow until frost. (The soybean, on the other hand, has a determinate type of growth, flowering, producing seed, and stopping growth after maturity.) The cowpea is therefore desirable for hay, grazing, and plowing under in the South, where the long growing season makes possible a long period of usefulness.

About one third of the United States crop is grown for seed production, and most of this is used for human food and seed for planting. The peas for food are harvested as green pods, green beans to be canned, and dry beans. Average yields, ranging from 5.5 to 6.5 bushels per acre, are so low compared with those of soybeans that the cowpea does not compete with the soybean for dry bean production for animal use.

For many years Southern farmers have used the cowpea for soil enrichment, since its heavy growth of nitrogen-rich foliage is excellent for replenishing depleted soils. Nevertheless, the trend has been toward the use of other types of legumes for this purpose, since the cowpea is comparatively less economical when all factors are considered.

Like other crops, the cowpea is subject to disease and insect attack. A wilt disease usually causes most damage when it appears. Bean rust is another disease of some importance. Nematodes do great damage in some areas and the bollworm often attacks the crop, especially in late summer. The best means of controlling diseases and insects is to practice crop rotation and clean cultivation. Some work has been done to develop disease-resistant varieties. The principal varieties grown in the United States are Black, Brabham, Clay, Groit, Iron, Monetta, Ripper, New Era, Taylor, and Whippoorwill.

Consult Mone, W. J., *Cowpeas: Culture and Varieties*, Farmers' Bulletin No. 1148, rev., U.S. Dept. of Agriculture (Washington 1924).

COWPENS, kou'pénz, locally küp'énz, town, South Carolina, in Spartanburg County, near the North Carolina line, is located nine miles east-northeast of Spartanburg, on the Southern Railway. The manufacture of textiles is the chief

industry. Others include machinery and food products. Nearby is Cowpens National Battlefield Site, established in 1929 to mark the victory gained Jan. 17, 1781 by American forces under Brig. Gen. Daniel Morgan over a British division under Lieut. Col. Banastre Tarleton. Cattle pens here gave the town its name in the 1700's. It is governed by a mayor and council. Pop. (1950) 1,879.

COWPENS, Battle of, in the American Revolution, Jan. 17, 1781. At the end of 1780 Lord Charles Cornwallis held South Carolina with a little over 3,000 men, having lost about 1,100 with Maj. Patrick Ferguson two months before, at Kings Mountain. Waiting for reinforcements, he lay at Winnsborough, north of the center, within supporting distance of Fort Motte and Orangeburg in the center, Charleston and Georgetown on the coast, and Augusta and Ninety-Six in the west. In December, Maj. Gen. Nathanael Greene entered the state with only 2,000 men, but with several subordinate leaders fit for separate commands. With 1,100 men he occupied Cheraw Hill in the northeast and kept Cornwallis in alarm for his communications with the coast. Under Brig. Gen. Daniel Morgan he sent 9,000 men (part militia, part regulars) to join the victors of Kings Mountain and to alarm Cornwallis for the western posts. Cornwallis moved north into North Carolina to force a like movement on Greene and sent Lieut. Col. Banastre Tarleton with 1,100 men after Morgan.

The Americans took post in a pasture ground called the Cowpens, near the northern boundary, a few miles southwest of Kings Mountain and just west of Broad River. A long slope led to a low rise; then came a depression, succeeded 150 yards farther by another rise; and in rear of this was the river, cutting off retreat. Morgan's move was in violation of all military rules, but he was a man of genius and used to militia; he said that he could ask but one thing better—and that was to have them entirely surrounded by the enemy, so that they could not run. Tarleton came in sight on the morning of Jan. 17, 1781, and Morgan placed his militia 150 yards in front of the first hill, with injunctions to fire at least two volleys at close range before breaking; on the hill, the famous 1st Maryland regulars, with some fine Virginians; on the second hill, his cavalry under Col. William Washington, a second cousin of George. As the British closed, the militia did not break; they were under Col. Andrew Pickens and fired many more than the two volleys with destructive effect. Finally forced back, they retired to the left around the hills to the river bank, in rear of the cavalry, to reform. The British left stretched around to flank the right of the American regulars, who withdrew to face them; the British thought them retreating and hurried forward in some disorder. Just then Colonel Washington's cavalry charged around the two hills to the left, coming up to the militia's old position and taking the British in rear, with the river on their flank; the militia rushed around the hills to the right, taking them in flank on the left; and the Continental regulars, only 30 yards off, poured in a withering fire and charged with bayonets. Hannibal himself neither wrought a finer piece of tactics nor caught an enemy in a deadlier trap. Most of the British troops threw down their arms; the remnant fled with Tarleton, who barely escaped being cut down

by Colonel Washington's saber. Of the British 270 were killed or wounded and 600 were captured, with 2 fieldpieces and 1,000 small arms. The Americans lost 12 killed and 62 wounded. Nearly a third of Cornwallis' army, including all his light troops, were annihilated at a blow.

COWPER or COOPER, kōō'pēr, William, English anatomist and surgeon: b. Petersfield, Sussex, England, 1666; d. London, March 8, 1709. Considered the foremost anatomist of his time, Cowper gave a classic description of aortic insufficiency and made valuable contributions to the study of muscles. However, he is remembered chiefly for the first satisfactory description of the bulbo-urethral glands, which later were called Cowper's glands. He was the author of *Myotomia Reformata* (1692), *The Anatomy of Humane Bodies* (1698), and *Glandularum . . . Descriptio* (1702).

Consult Cole, F. J., *History of Comparative Anatomy: From Aristotle to the Eighteenth Century* (New York 1944).

COWPER, William, 1ST EARL COWPER, English jurist: b. about 1665; d. Hertfordshire, England, Oct. 10, 1723. Called to the bar in 1688, he served in the House of Commons from 1695 until he was made lord keeper of the great seal in 1705. He played a leading role in the union of Scotland with England (1706) and was the first lord chancellor (1707-1710). He left office with the Whigs in 1710, when their unpopularity reached its peak at Dr. Henry Sacheverell's trial, at which Cowper presided. Under George I he became again lord chancellor (1714-1718) and was created (1718) Viscount Fordwich and Earl Cowper. Although he gave ill-health as his reason for retirement (1718), political intrigue was more probably the cause. Cowper's contemporaries considered him a consummate orator in parliamentary debate. Cowper's private diary, edited by E. C. Hawtrey, was published in 1844.

COWPER, William, English poet: b. Great Berkhamstead, Hertfordshire, England, Nov. 15, 1731; d. East Dereham, Norfolk, April 25, 1800. At 10 he entered Westminster School and showed fondness for athletics and literary studies; but he also displayed some morbidity, particularly in religious matters. After eight years at Westminster and nine months at home, he was articled for three years to a London solicitor. Later he described these and the following 12 years as misspent, meaning that he thought little about the state of his soul and enjoyed visiting the three attractive daughters of his uncle, Ashley Cowper. In 1752 he took chambers in the Middle Temple. He was called to the bar in 1754, but made few efforts to secure clients, his conduct being partly explained by the fact that in 1753 he was afflicted with a sort of mental dejection that for many months paralyzed his energies. Finally, after he had received consolation from George Herbert's poetry and had had his "hard heart" softened by prayer, a visit to the seashore completed a temporary cure.

In 1756 his father died; the same year his suit for the hand of his cousin, Theodora Cowper, was rejected by his uncle. She remained true to him, and shortly after her death the love poems which he wrote to her were published (1825). Cowper does not appear to have been

inconsolable. In 1759 he bought a suite of chambers in the Inner Temple and was made a commissioner of bankrupts, at which time he habitually spent more than his income. In his pecuniary stress he obtained from his cousin, Maj. William Cowper, the gift of the patent office of clerk of the journals of the House of Lords. But his kinsman's right to bestow the post being questioned, it was decided that Cowper's fitness must be tested by an examination. He broke down in his preparation for this and, as the ordeal drew near, grew more and more despondent. Finally he made three vain attempts to commit suicide (November 1763). The idea of his securing the office had to be abandoned, and a few weeks later he was placed in the private asylum kept at St. Albans by the poet-physician, Dr. Nathaniel Cotton.

After about five months he began to improve. He continued at the asylum, however, until June 1765, when he removed to Huntingdon, resolving to break away forever from his former life. He became practically a recluse, but he had acquired the urbanity which was to be so marked a characteristic of his poetry and of his correspondence.

In Huntingdon Cowper began his famous friendship with the family of the Rev. Morley Unwin, particularly with the latter's pious wife (Mary Cawthorne) and his son, later the Rev. William Cawthorne Unwin. They took Cowper as a boarder, and at last his religious aspirations were satisfied. Every day was spent in attending church twice, in singing hymns, and in reading and conversing on evangelical topics.

In the summer of 1767 the elder Unwin was killed in a fall from his horse. John Newton, curate of Olney, persuaded Mrs. Unwin and Cowper to move to that town, which has since been associated with the poet's memory. They took a house called Orchard Side, and Cowper found congenial employment in assisting Newton in his work among the poor and in writing hymns. In 1770, on the death of his brother John, Cowper wrote *Adelphi* (published 1802), an account of that clergyman's conversion to evangelical tenets. Two years later he and Mrs. Unwin became engaged, but all thoughts of marriage were soon dispelled by Cowper's third derangement, which began in January 1773 and lasted until May 1774. After a terrible dream in February 1773, he seems never to have been able to believe for long that there was any hope of his salvation. Yet, when he had outwardly recovered, he strove not to exert a depressing influence on others and he took much pleasure in keeping a garden, building his summer house, and describing to correspondents such local events as the Olney fire of 1777. In 1799 Newton published the *Olney Hymns*, of which 68, including *Oh for a Closer Walk with God* and *God Moves in a Mysterious Way*, were by Cowper. Later in the same year Newton accepted a rectory in London. Whether his intense nature had oppressed Cowper's mild genius is a moot point. It is at least certain that the latter's literary career commenced in full after Newton had left Olney.

Under the encouragement of Mrs. Unwin, Cowper began to work steadily upon a series of didactic, semisatiric poems—*Progress of Error*, *Truth*, *Table Talk*, and *Expostulation* (December 1780-February 1781). Newton acted as a friendly critic and secured a publisher for the volume, which, with the addition of *Hope*, *Charity*, *Com-*

versation, Retirement, and some shorter pieces, appeared in February 1782 and was moderately successful. Time has shown not only that it contained many apt passages of observation and reflection, but that it heralded a departure, not too violent, from the overpolished style and somewhat metallic versification of Pope.

Meanwhile, the poet had made the acquaintance of Lady Austen, a baronet's widow who was visiting near Olney. The intimacy, which Mrs. Unwin shared, became too intense to last more than a few years; but, whatever Lady Austen's disappointments, we owe to them two of Cowper's best poems—the humorous ballad of *John Gilpin* (1782), based on a story which she told Cowper to dispel his melancholy, and *The Task*, his great discursive poem in blank verse, which, beginning with Lady Austen's theme, the sofa, broadened into reflections upon life and descriptions of nature unrivaled in their day and in respect to realistic fidelity and homely charm not clearly surpassed since. *The Task* was probably begun in July 1783 and was finally published in June 1785, along with *John Gilpin* (which had been circulated in periodicals), the admirable *Epistle to Joseph Hill*, and *Tirocinium*, a satire upon current education (1782–1784). Cowper meanwhile had begun his translation of the *Iliad* in blank verse and had written some of his shorter poems like *The Poplar Field*. All this time he believed firmly that God had abandoned him and that it was his duty not to pray, since that would imply a questioning of the righteousness of the divine decree.

The Task, helped by the vogue of *John Gilpin*, attained success. Cowper became the chief poet of the day and secured a popularity which lasted well into the next century. His relatives began to pay more attention to him, and in Lady Hesketh, sister of his former love Theodora, and the Rev. John Johnson, of Norfolk, he found supporters during the trying years which were in store for him. His income was increased, and with Lady Hesketh's aid he and Mrs. Unwin moved from Olney to the neighboring Weston in November 1786. Shortly afterward they were shocked by William Unwin's sudden death. At that time Cowper suffered his fourth derangement, which lasted from January to June 1787. He recovered rather speedily and worked at Homer, wrote excellent short poems, and resumed his correspondence, while continuing to suffer from hallucinations and melancholia. In September 1788 he began translating the *Odyssey*, and the complete Homer, including the *Batrachomyomachia*, was published by subscription in July 1791 with a success which time has not ratified. Posterity much prefers the pathetic lines *On the Receipt of My Mother's Picture out of Norfolk*, written in the spring of 1790. Having been assured by a demented schoolmaster-friend named Teedon that heaven was willing, Cowper undertook to edit an elaborate edition of his favorite, Milton. The scheme came to little, but it was the occasion of his forming a warm friendship with his future biographer, William Hayley, to whom he paid a visit in August 1792, accompanied by Mrs. Unwin, who had been partly incapacitated by paralysis. Mrs. Unwin's health sank steadily, and Cowper, in a sad state himself, became in his turn the indefatigable nurse. The lines *My Mary* commemorate the melancholy situation. In January 1794, Cowper was seized with his old complaint and sank into a stupor, from which

he practically never rallied. He did not appreciate the fact that he had been granted a pension of £300 by the government. Mrs. Unwin also grew worse, and but for the ministrations of Lady Hesketh, Hayley, and John Johnson, the last six years of Cowper's life would have been a stretch of unrelieved gloom. In July 1795, Johnson removed the two invalids to Norfolk. They settled finally at East Dereham, where on Dec. 17, 1796, Mrs. Unwin died, the event producing little emotion in the man who loved her. Cowper continued in his state of dejection, though he could still work at the revision of his *Homer*. His only important original composition during the period was the poignantly pathetic *Cast-away*, written March 20, 1799. He still persisted in believing that God had forsaken him, and in this belief he died April 25, 1800. He was buried in East Dereham Church beside Mrs. Unwin.

Cowper's importance as a precursor of Wordsworth as well as the positive excellence of many of his descriptive and satiric passages and of his humorous and pathetic shorter poems are generally acknowledged. If his range of work were sufficiently taken into account—his heroic odes, his familiar verse, his humorous ballads, his poems of domestic affection, his verses on animals (in which he is almost unrivaled), his reflective lyrics, his satires and his faithful descriptions of quiet life and English nature—he would be ungrudgingly pronounced a great classic. As a correspondent his supremacy is generally allowed.

To his works enumerated above should be added the unpleasant satire *Anti-Thelyphthora* (1781), and *Latin and Italian Poems of Milton* (1808).

WILLIAM P. TRENT,
Late Professor Emeritus of English Literature,
Columbia University.

Bibliography.—The first edition of William Hayley's biography of Cowper, with letters and supplementary material, appeared in four volumes between 1803 and 1806. In 1835 T. S. Grimshawe edited the life and letters in eight volumes. However, Robert Southey's edition of Cowper's works together with his life of Cowper, in 15 volumes (1834–37), is still the standard work. A good modern edition of Cowper's works, containing a bibliography of the earlier editions, is that of H. S. Milford (3d ed., Oxford 1926).

C., *William Cowper: Humanitarian* (Chapel Hill, N.C., 1938); Thomas, G. O., *William Cowper and the Eighteenth Century*, 2d ed. (London 1949).

COWPOX. See CATTLE, DISEASES OF.

COWRIE or **COWRY**, kou'ri, any snail in the family Cypræidae, a family of marine snails which contains upwards of 300 species, generally highly colored and glossy, considered among the most beautiful of the marine shells. The cowries are confined to tropical and subtemperate regions. A few species are found in the West Indies and the Atlantic coast of Central and South America. A few other species live along the Pacific coast of Central and South America, and in North America, as far north as southern California. The greatest number of the species, however, appear in the tropical portions of the vast Indo-Pacific region.

The Money Cowrie (*Cypræa moneta*) once was used extensively as money, particularly in Africa, and to a less extent in other portions of the world. It still is used in a limited way

in remote sections of Africa as a means of trade. The supply of these cowries came mainly from coral-reef areas of the East Indies.

COWRY BIRD. See NUTMEG BIRD.

COWSLIP, kou'slip, a common name often applied to marsh marigold (*Caltha*), a genus of about 20 glabrous perennials of the cold temperate and arctic regions of both hemispheres, belonging to the crowfoot family (Ranunculaceae). Two species of *Caltha* occur in the eastern United States: *C. palustris*, cowslip or kingcup, with yellow flowers, and the smaller *C. nutans*, with white or pinkish flowers and floating stems, which is rare and local in its distribution. Half a dozen other species are found in the western United States.

Cowslip is also used to two genera of the primrose family (Primulaceae): the primrose (*Primula*) and the American cowslip (*Dodecatheon*). The primroses are low perennial herbs, mostly of boreal or alpine distribution (one or two in southern South America), with single or tufted and simple scapes, and flowers in umbels. The European cowslip (*P. veris* or *P. officinalis*) has large yellow or purple corollas and is often found as an escape from cultivation. Four species of primrose with white, yellow, or lilac corollas are native in eastern North America. *Dodecatheon*, a genus of mostly western species, is represented in the eastern states by the shooting star (*D. Meadia*) with lilac, pink, or violet, showy, nodding flowers, and another species (*D. amethystinum*) with deep red-purple flowers and limited distribution.

COWWHEAT, kou'hwët, a genus (*Melampyrum*) of about 15 species of erect branching semiparasitic annuals of the Northern Hemisphere belonging to the figwort family (Scrophulariaceae), is represented in North America by the highly variable narrowleaf cowwheat (*M. lineare*) and its four varieties. This species may be two feet tall, has white flowers, and black seeds (as indicated by the generic name). It is found in Canadian woods from Labrador to British Columbia, but in the United States mostly in the east from New England to Georgia.

COX, köks, David, English landscape painter: b. Deritend, near Birmingham, England, April 29, 1783; d. Harborne, near Birmingham, June 7, 1859. Drawn to painting as a schoolboy, before the age of 20 he found work as a painter of scenery in English and Welsh theaters. To increase his income after marriage in 1808, Cox taught drawing in schools until 1820 and thereafter took private pupils occasionally. In nearly every year from 1820 until his death Cox took sketching tours in England and especially in Wales. His election to the Society of Painters in Water-colours in 1813 preceded his publication of *A Treatise on Landscape Painting and Effect in Water-colours* . . . (1814). After 1839 he turned more to oils as a medium, in which he did very skillful work, but Cox is remembered mostly for his water-color paintings of Welsh landscapes and is ranked among the best English painters of landscapes. His colors are pure and fresh, his treatment of light and shade is superb, in small productions he excels. Some of Cox's drawings are in the British Museum and the South Kensington Museum, London, others are

in the Birmingham Art Gallery, but his best water-color paintings are in private collections.

COX, SIR George William, English clergyman and historian: b. Benares, India, Jan. 10, 1827; d. Walmer, Kent, England, Feb. 9, 1902. He was educated at Trinity College, Oxford, and was ordained in 1850. After serving several parishes, he became rector of Scrayingham, Yorkshire (1881-1897). In 1877 he succeeded his uncle in the baronetcy. In 1886 he was chosen bishop of Natal by the friends of Bishop John W. Colenso, but the archbishop of Canterbury refused him consecration. Cox was the author of many historical works of popular character, several of which treated the history of Greece and the study of mythology and of folklore. Among his most important published works are *A Manual of Mythology* (1867), *A History of Greece*, 2 vols. (1874), and *The Life of John William Colenso, D.D., Bishop of Natal*, 2 vols. (1888).

COX, Jacob Dolson, American soldier and statesman: b. Montreal, Canada, Oct. 27, 1828; d. Magnolia, Mass., Aug. 8, 1900. After graduating from Oberlin College in 1851, he taught school in Warren, Ohio, for two years, and in 1853 he began the practice of law there. At the outbreak of the Civil War he was made a brigadier general of the Ohio Volunteers. In 1862 he became major general of the United States Volunteers and in 1864 he commanded a division at Nashville. Cox was elected governor of Ohio in 1865, but lost favor with his party over his opposition to Negro suffrage and was not renominated. In 1869 he became secretary of the interior in President Ulysses S. Grant's cabinet. He resigned office in 1870 after differences with Grant about the need for civil service reform, Cox being supported by progressive opinion in general; his political "martyrdom" had, in all likelihood, a hastening effect on the establishment of subsequent reform.

Cox resumed the practice of law, but in 1873 he became the president of the Wabash Railroad. He served one term (1877-1879) in Congress, after which he retired from public life, becoming (1881) dean of the Cincinnati Law School. From 1874 until his death he was military critic for the *Nation*, and his published books and articles earned him a reputation as one of the foremost military historians of his time. Included among his works are *Atlanta, The March to the Sea, Franklin and Nashville*, and *The Battle of Franklin*; his *Military Reminiscences of the Civil War* was published posthumously in two volumes in 1900.

COX, James Middleton, American journalist and statesman: b. Jacksonburg, Ohio, March 31, 1870. Educated in the public schools of Ohio, he was employed in a printer's office, taught in a country school, became a newspaper reporter, and was for a time on the editorial staff of the Cincinnati *Enquirer*. In 1898 he became proprietor of the Dayton *Daily News*, the first of eight newspapers which he eventually owned. He served in Congress from 1909 to 1913 and was governor of Ohio (1913-1915, 1917-1921). In 1920 he was the unsuccessful Democratic candidate for the presidency. In 1933 he served as vice chairman of the United States delegation to the World Monetary and Economic Conference in London. His autobiog-

raphy, *Journey Through My Years*, appeared in 1946.

COX, Kenyon, American painter: b. Warren, Ohio, Oct. 27, 1856; d. New York, N. Y., March 17, 1919. He began the study of art in Cincinnati and at the Pennsylvania Academy of Design. From 1877 to 1882 he worked in Paris under Carolus Duran and Jean Léon Gérôme. Returning to America, he settled in New York City, and embarked on a varied career, painting, illustrating, and writing. He is known principally as a mural painter: decorations by him are in the Library of Congress in Washington, in the state capitol at St. Paul, Minn., and in courthouses in New York, Newark, Jersey City, and Wilkes-Barre. His paintings are on view in many of the large museums of the United States, including the Metropolitan Museum in New York, N. Y., and the National Gallery in Washington, D.C. He was the recipient of various awards, among them the Medal of Honor for Mural Painting bestowed in 1910 by the Architectural League. He was a member of the Society of American Artists, the American Academy of Arts and Letters, and the National Academy. Cox was a writer of artistic criticism as well as a painter; he received the degree of doctor of letters from Oberlin and Dartmouth colleges. Besides numerous reviews and magazine articles, he published six volumes of criticism on art, *Old Masters and New* (1905), *Painters and Sculptors* (1907), *The Classic Point of View* (1911), *Artist and Public* (1914), *Winslow Homer* (1914), and *Concerning Painting* (1917).

Consult Smith, Minna C., "The Work of Kenyon Cox," *International Studio*, vol. 32 (1907); Mather, Frank J., *Kenyon Cox* (New York 1919).

COX, Louise Howland King, American artist: b. San Francisco, Calif., June 23, 1865; d. Windham, Conn., Dec. 10, 1945. She studied art in New York City at the National Academy of Design and at the Art Students' League under Kenyon Cox, whom she married in 1892. In 1900 she received a medal at the Paris Exposition and was the recipient of many other honors. She was a member of the Society of American Artists and was an associate of the National Academy. Louise Cox was especially talented as a painter of children and made many portraits of her own three children. Although she seldom exhibited her work, it is represented in many private collections in the United States and also in the National Gallery of Art in Washington, D.C.

COX, Palmer, Canadian author and illustrator: b. Granby, Quebec, Canada, April 28, 1840; d. there, July 24, 1924. Originally a contributor of cartoons and verse to newspapers in California, where he settled in 1863, Cox first attained success with the publication of *Squibs of California, or Every-Day Life Illustrated* in 1875. In that year he moved to New York and in 1880 began to illustrate stories for *St. Nicholas Magazine*, where his famous "Brownie" series first appeared. In book form his "Brownie" stories sold over a million copies during his lifetime. He also wrote *Hans Von Pelter's Trip to Gotham* (1876), *How Columbus Found America* (1877), and *That Stanley* (1878). Two plays, both written in 1895, were

produced on the stage: *The Brownies in Fairyland*, a cantata in two acts, and *Palmer Cox's Brownies*, a three-act play which ran almost five years.

COX, Richard, English prelate: b. Whaddon, Buckinghamshire, England, 1500; d. Ely, July 22, 1581. Educated at Eton and King's College, Cambridge, he was invited by Thomas Cardinal Wolsey to join his new foundation of Christ Church, Oxford. He is known to have supported King Henry VIII's divorce in 1530, and by 1540 he was one of the 15 divines settling crucial church questions. He was among those who declared the marriage of Henry and Anne of Cleves null and void in 1540. In the same year he became archdeacon, in 1542 prebendary of Lincoln, and in 1547 dean of Christ Church, Oxford. At the accession of Edward VI (1547), Cox advanced rapidly, becoming dean of Westminster Abbey in 1549. His zeal in eradicating all manuscripts, books, and statutes savoring of Romanism while he was chancellor of Oxford (1547-1552) earned him the nickname of "cancellor" of the university.

After the death of Edward (1553) Cox was arrested on suspicion of being engaged in Northumberland's plot to seize power, but he escaped to the Continent, where he lived in exile at Frankfurt on the Main (1555-1559). Here John Knox, under Calvinistic influence, had persuaded adoption of a service far more puritanical than that of the Book of Common Prayer established under Edward VI. Cox opposed such doctrine, and the two factions, which came to be known as Knoxians and Coxians, split the city into rival parties. Although Knox accused Cox of pluralism, the latter charged him in turn with treason against the emperor, Charles V. Knox and his followers were banished from the city, and the Book of Common Prayer was restored.

In 1559, after Elizabeth I's accession, Cox returned to England, where he first was created bishop of Norwich, but shortly thereafter was translated to the see of Ely. He remained there for 21 years, a period marked by his harshness, intolerance, power-seeking, and enmity to Roman Catholics; he refused to serve in the queen's chapel because of the presence of candles and the crucifix. His arbitrary judgments were felt also by Puritans and Protestants, and he was in frequent conflict over his property, much of which he was subsequently forced to cede to his enemies and accusers. The hostility of the court caused him to request permission to resign his see, which he did in 1580, receiving a pension of £200 and the palace of Doddington.

Cox translated the Acts of the Apostles and the Epistle of St. Paul to the Romans for the Bishops' Bible, and assisted in compiling and then in revising the first Book of Common Prayer.

COX, Samuel Hanson, American clergyman and educator: b. Rahway, N. J., Aug. 25, 1793; d. Bronxville, N. Y., Oct. 2, 1880. Originally studying for the legal profession, he abandoned it for the study of theology and was ordained to the Presbyterian ministry in 1817. From 1817 until 1854 he held pastorates in New Jersey and New York; during these years he was outspoken in his antislavery views. As a leader in that movement, he was burned in effigy in Charleston.

S. C. (1835). He was a director of Union Theological Seminary and a founder of New York University. From 1856 to 1863 he was head of Ingham University in New York State. Cox was the author of *Quakerism not Christianity* (1833) and *Interviews, Memorable and Useful* (1853).

COX, Samuel Sullivan, American statesman and author: b. Zanesville, Ohio, Sept. 30, 1824; d. New York, N. Y., Sept. 10, 1889. After graduating with high honors from Brown University in 1846, Cox studied law and was admitted to the Ohio bar, but soon turned to literature and travel. After the publication of *A Buckeye Abroad* (1852), he became editor of the *Ohio Statesman*, where he earned his lifelong nickname "Sunset" after an extraordinarily rhetorical description of a sunset. He served as a Democratic member of Congress from Ohio (1857-1865), and from New York (1869-1873, 1875-1885, 1887-1889). In 1885 he was appointed by President Grover Cleveland as ambassador to Turkey, but resigned after a year. He was called the Letter Carriers' Friend for his efforts in their behalf for better working conditions, and a statue of Cox stands in Astor Place, New York City, erected by the letter carriers. Cox was a religious man of independent mind and a scholar of broad learning. He supported the Civil War, but stood for complete amnesty after its end.

A prolific writer, Cox was the author of a number of volumes of verse, and *Puritanism in Politics* (1863), *Why We Laugh* (1876), *Free Land and Free Trade* (1880), and *Three Decades of Federal Legislation* (1885).

COXALGIA, kōk-sāl'jī-ā, or **COXITIS**, kōks-ī'tis, a term formerly applied to a disease of the hip joint. It is characterized by inflammation, sometimes accompanied by suppuration, which leads to stiffness of the joint and its final destruction by necrosis.

COXE, Arthur Cleveland, American prelate and author: b. Mendham, N. J., May 10, 1818; d. Clifton Springs, N. Y., July 20, 1896. He was the son of Samuel Hanson Cox, but adopted an earlier spelling of the name. He took orders in the Episcopal Church in 1841 and after holding rectorships in Hartford, Conn., Baltimore, Md., and New York City, he was consecrated in 1865 assistant bishop of Western New York, of which diocese he became the bishop later in that year. He was a founder of the Christian Literature Company, for which he edited a series of *Ante-Nicene Fathers* (1885-1886). He published several volumes of ecclesiastical poetry, of which *Christian Ballads* (1840) was the best known and appeared in many editions. His strongly conservative influence was directed toward Christian unity and, through the Anglo-Continental Society, promulgation of the principles of the English Reformation. He wrote books controverting the Roman Catholic interpretation of history and opposed revision of the Bible on the ground that the Authorized Version was a bond uniting many churches. To support this thesis, he published (1857) his *Apology for the English Bible*.

COXE, Tench, American economist: b. Philadelphia, Pa., May 22, 1755; d. there, July

16, 1824. Whether or not Coxe was a Royalist at the time of the Revolution is debatable; however, as a Whig he was a member of the Annapolis Convention in 1786 and of the Continental Congress in 1788. He was assistant secretary of the treasury in 1789 and served (1792-1797) as commissioner of the revenue. After Coxe's break with the Federalists, Thomas Jefferson made him (1803) purveyor of public supplies, which office he held until 1812. He early devoted much attention to political economy, and his writings and ideas on this subject constitute his chief claim to remembrance. He favored the prohibition of the coasting trade to foreign shipping, the importation of foreign goods only in the ships of the country producing them, the special encouragement of the manufacturing industry, and the exemption of raw materials from tariff duties. He urged the South to cultivate cotton and is sometimes called the father of the American cotton industry. An important key to his economic outlook is his pamphlet (1787) *An Enquiry Into the Principles on Which a Commercial System for the United States of America Should be Founded*. A compilation of his papers, *View of the United States*, was published in 1794.

COXE, William, English traveler and historian: b. London, England, March 7, 1747; d. Bemerton, Wiltshire, June 8, 1828. He was educated at King's College, Cambridge, and in 1771 was ordained and took the curacy of Denham. He soon resigned to become the tutor of several young noblemen and spent many years traveling about the Continent with them; his accounts of these travels and his series of memoirs of 18th century figures are his chief claim to recognition. He published accounts of his travels in Switzerland, Poland, Russia, Sweden, and Denmark, these being translated into most of the languages of Europe. His most important works include *Memoirs of Sir Robert Walpole*, 3 vols. (1798); *History of the House of Austria . . . from 1218 to 1792*, 2 vols. (1807); *Memoirs of Horatio, Lord Walpole*, 2 vols. (1808); *Memoirs of the Bourbon Kings of Spain . . . from 1700 to 1788*, 3 vols. (1813).

COXEY, kōk'sī, Jacob Sechler: b. Selinsgrove, Pa., April 16, 1854; d. Massillon, Ohio, May 18, 1951. Leader in 1894 of the famous march of unemployed on Washington, D.C., he remained throughout his long lifetime one of the nation's most colorful personalities.

Educated in public schools at Danville, Pa., by 1881 he had established at Massillon a sandstone quarry which he operated until 1929. In 1894, amid the economic unrest which followed on the heels of the panic of 1893, Coxe organized a "living petition" of unemployed who marched as the Army of the Commonweal of Christ from Massillon, Ohio, to Washington, D.C., to petition the enactment of remedial legislation. In a parade down Pennsylvania Avenue on May Day, 1894, fewer than 500 Coxeites participated, and their leader was arrested for trespassing while delivering a speech from the Capitol steps. Perennially a candidate for public offices ranging from mayor to president of the United States, he was elected only once, serving as Republican mayor of Massillon from 1931 to 1933. He was the author of *Coxey's Own Story* (1914).

COXIE or **COXCIE**, kōk'sē, **Michiel van**, Flemish painter and engraver: b. Mechlin, Belgium, 1499; d. there, March 5, 1592. His works were long concealed under the signature M.C.O.-K.X.I.N., which accounts for variations in the spelling of his name. He was a pupil of Bernard van Orley and traveled to Rome, where he remained for several years, attracted by the work of Raphael, whom he probably knew personally. Here he executed many paintings in fresco and painted in the style of Raphael the *History of Cupid and Psyche*, which was engraved on 32 copperplates. In the Imperial Gallery in Vienna there is a *Madonna with the Infant Jesus* by him. He was appointed court painter by Philip II of Spain and was commissioned to copy the altarpiece of the brothers Van Eyck in Ghent. He painted in a cold but clearly defined style, and there are good examples of his work in the museums of Madrid, Vienna, Prague, Brussels, and Antwerp, but his works are rare even in the Netherlands.

COXITIS. See **COXALGIA**.

COXSWAIN or **COCKSWAIN**, kōk's'n or kōk'swān, a minor officer on board a ship, who commands a boat's crew in the absence of superior officers and usually steers the boat. The term also designates the helmsman of a racing crew.

COYOTE, kī'ōt or kī-ōtē, prairie wolf (*Canis latrans*), native to the western United States, and before the advent of civilization numerous as far east as the extent of the prairies of the Mississippi Valley, where it was called the red wolf in distinction from the large gray or timber wolf. It is abundant in open country from Alaska and British Columbia south to Central America. Coyotes are smaller than other wolves, being about the size of setter dogs, and, although they often travel in packs, as do other wolves, they are cowardly where man is concerned and confine their raids to the brute creation. Their fur is soft, reddish or tawny-gray in color, sometimes slightly tipped with black. The tail is bushy, the ears are upright, and the slender muzzle is very pointed. Coyotes live in hollows among rocks or in deserted burrows, whence they usually issue at dusk to hunt. Their food is chiefly gophers, mice, ground-nesting birds, prairie dogs, rabbits, sheep, and goats. Their depredations on cattle ranches are mainly reserved for winter. In former days they were persistent enemies of the pronghorns. They are fleet footed, and cunning in avoiding snares. They adapt themselves readily to varying conditions.

COYPEL, kwā'pēl, a celebrated family of French artists.

NOËL COYPEL: b. Paris, France, Dec. 25, 1628; d. there, Dec. 24, 1707. After he had embellished, by the royal command, the Louvre with his paintings (from the cartoons of Charles Le Brun) and had in like manner adorned the Tuileries, Fontainebleau, and Versailles, he was appointed director of the French Academy in Rome (1672). His chief works are the *Martyrdom of Saint James* (in the Cathedral of Notre Dame), *Cain Murdering His Brother* (in the Louvre), the *Trinity and the Conception of the Holy Virgin* (in the Hôtel des Invalides). He

became director of the Royal Academy of Painting and Sculpture in 1695.

ANTOINE COYPEL, his son: b. Paris, France, April 11, 1661; d. there, Jan. 7, 1722. At the age of 20 he was elected to the Royal Academy of Painting and Sculpture; in 1707 he became professor there and in 1714 its director. He was made painter to the king in 1716 and painted many pictures for the royal palaces and the churches of Paris. Among his best works are 12 subjects from the *Aeneid*, a portrait of Molière, and *Jugement de Paris*. The designs of the *Histoire numismatique du règne de Louis XII'* are mostly his. His collected lectures were published under the title *Discours sur la peinture* (1721).

NOËL NICOLAS COYPEL: b. Paris, France, Nov. 18, 1690; d. there, Dec. 14, 1734. He excelled in mythological painting. His best-known pictures are the paintings in the Chapel of the Virgin at the Church of St. Saviour. He became a member of the Royal Academy of Painting and Sculpture in 1720, professor there and court painter in 1731.

CHARLES ANTOINE COYPEL, etcher, painter, and dramatist, son of Antoine: b. Paris, France, July 11, 1694; d. there, June 14, 1752. He studied with his father. At court his dramas made him very popular, especially *Les folies de Cardenio* (1720). His 25 pictures from the history of *Don Quixote* (at the Palace of Compiègne) were very well known. He painted in pastel and also numerous portraits. In 1715 he was admitted to the Royal Academy of Painting and Sculpture, became professor there in 1722, chief court painter in 1747, and director of the academy in the same year.

Consult Pierre Marcel, *La peinture française au début du XVIII^e siècle* (Paris 1906).

COYPU, koi'pōō, or **NUTRIA**, nū'trī-ā, an aquatic rodent (*Myocastor coypus*), native to South America from Peru southward. It is known colloquially as the nutria and its pelt furnishes the fur commercially used in hats and coats. It is dull brown, has a gray muzzle and yellow incisors. Its nostrils are so set that it can breathe when all immersed except the top of its nose. It is somewhat smaller than the beaver and has a slender, ratlike tail. It is distinctly aquatic, dwelling in ponds, and burrowing into the banks or building platform nests among the reeds on the shore. Owing to the threatened extermination of the coypu, local laws have been enacted for its protection as a valuable fur-bearing animal. In the 1930's coypus were imported into the United States, where they abound in the southwest and are important in the fur industry.

COYSEVOX, kwāz-vōks', **Antoine**, French sculptor: b. Lyon, France, Sept. 29, 1640; d. Paris, Oct. 10, 1720. He studied with Louis Lerambert, was admitted to the Royal Academy of Painting and Sculpture in 1676, was employed by Louis XIV in decorating Versailles and Marly. Among his best works are an equestrian statue of Louis XIV; the statue of Jules Cardinal Mazarin; the tomb of Jean Baptiste Colbert; the *Crouching Venus*; the *Nymph of the Shell*; and the *Hamadryad*. He did portrait busts and statues of Louis II de Bourbon, prince de Condé; François de Salignac de la Mothe-Fénelon; Jean Baptiste Racine; Charles Le Brun;

and Marie Thérèse. His work may be seen in Paris at the Louvre, the Tuileries, and various churches, at Versailles, and elsewhere.

COZAD, kô-zăd', city, Nebraska, in Dawson County; altitude 2,487 feet; on the Platte River; 50 miles west of Kearney; on the Union Pacific Railroad. It calls itself "the alfalfa shipping center of the world." Irrigation siphon tubes are made here. Founded in the early 1870's by an Ohioan, John J. Cozad, it was incorporated in 1905. Pop. (1950) 2,910.

COZENS, kûz'nz, John Robert, English water-color painter: b. London, England, c.1752; d. c.1799. A pupil of his painter father, Alexander Cozens (d. 1786), a reputed natural son of Peter the Great by an Englishwoman of Delftford, Cozens visited Switzerland and Italy in 1776 with Payne Knight, and in 1782 toured Italy with William Beckford, for whom he executed many wash paintings. He was the first English water-color painter to sketch in Italy and the Alps. He suffered a mental collapse in 1794, from which he never recovered. Among his English subjects are some fine studies of trees in Windsor Forest. Painting first in monochrome, he later widened his color range. A forerunner of the Impressionists, his handling of composition departed from traditional practice, and his treatment of light was highly sensitive. John Constable paid tribute to the poetic quality of his work, and Joseph M. W. Turner acknowledged an important debt to Cozens' oil painting of Hannibal's march over the Alps (1776). Examples of Cozens' work may be seen at the Victoria and Albert Museum and the British Museum.

COZUMEL, kô'sô-měl', island, Caribbean Sea. Located off the northeast coast of Quintana Roo territory, Mexico, at latitude 20° 34' N. and longitude 86° 44' W., it is 29 miles long and 9 miles wide. It is low, tree-covered, and fertile, and abounds in fruit and cattle. Many remains of ancient Maya buildings have been discovered on it. When Juan de Grijalva visited it in 1518 it contained a large population, and was regarded as a place of peculiar sanctity by the Indians of the neighboring continent.

CRAB, a common name applied to the short-tailed (brachyurous) decapod (ten-legged) crustaceans. The head, provided with short feelers, two stalked eyes, and feeding appendages around the mouth, is inseparably fused with the thorax into one piece, the cephalothorax, covered with a hard shell (carapace) whose sides conceal the gills. In typical crabs the cephalothorax is square across the front and wide from side to side. The thorax bears five pairs of legs, the first pair of which usually terminate in large defensive claws (chelae). The outstanding feature of brachyurous crustaceans is the greatly reduced abdomen or tail kept folded out of sight under the thorax. The sexes are easily distinguished by external features. The female fastens her eggs to the under side of her abdomen, where they form a protruding mass called the sponge. This hatches in about two weeks to a minute larva (zoea) having no resemblance to a crab. After several molts the zoea becomes another strange larval type, the megalops, which molts into a tiny crab. Growth to the adult

stage involves a large number of molts, extending over about a year.

Most crabs are marine, inhabiting more or less rocky bottom, where they live in burrows or retreats in the rocks. They run about at night on the tips of their legs, seeking food, mostly animals. The sidewise locomotion is characteristic. In some the last pair of legs is broadened for swimming. Fresh-water crabs live in streams in tropical and subtropical countries. The tropics also abound in land crabs, which live in burrows in sandy shores and mud flats, and run about at night in search of food. Among these is the ghost crab of the Atlantic coast. Land crabs go down into the water to hatch their eggs, as they have the same aquatic larvae as other crabs.

The common edible crab or blue crab (*Callinectes sapidus*) of the Atlantic coast is a swimming crab, whereas the Pacific and European edible crabs of the genus *Cancer* lack swimming capacity. Soft-shelled crabs are obtained for the market by capturing crabs about to molt and keeping them in floats until the old shell is shed; the new shell remains soft for several hours.

Among other types of crabs are the spider crabs, which have distinctively long legs and a smaller triangular cephalothorax with pointed head end. These include the giant spider crab of Japan with legs about three feet long. Spider crabs do not burrow but live mostly among

Crab (*Cancer irroratus*).

seaweeds, and many have the habit of fastening seaweeds, sponges, and other organisms to their backs as a means of concealment. The fiddler crabs (*Uca*) are distinguished by their single, relatively large chela, found only in the male sex. The oyster or pinnotherid crabs generally live inside bivalves and other animals, clinging to the gills, on which they inflict some damage, and robbing the host of food. The box crab is a thick-shelled crab of the genus *Calappa*. Some other marine crustaceans called crabs, such as hermit crabs and mole crabs, are not true crabs, but belong to the anomorous decapods.

CRAB APPLE or **CRAB**, a common name for various native American and introduced Asiatic apples with small, acid fruits suitable for preserves or pickles. All crabs are either shrubs or small trees belonging to the genus *Pyrus* (subgenus *Malus*) of the rose family (Rosaceae). Native American species are the narrow-leaved crab apple (*P. angustifolia*), with fragrant pink flowers and greenish-yellow sour fruits about 1 inch in diameter used for jelly, and its thorny variety *spinosa*; the highly ornamental and variable American crab apple (*P. coronaria*), with sweetly scented rose flowers and yellow-green sour fruits about 1½ inches in diameter; the western crab apple (*P. ioensis*), which crosses freely with other species, one of its commonest hybrids with apple being known as Soulard crab (x. *P. Soulardi*); and the Oregon crab apple (*P. fusca*), with white flowers, the only species found on the Pacific coast. Well-known introduced crabs are the Chinese apple (*P. prunifolia*) and the Siberian crab (*P. baccata*), with a small red or yellow fruit. Some of the many cultivated forms escape easily from cultivation. The common cultivated apple hybridizes readily with wild forms.

CRAB ISLAND, West Indies. See VIEQUES.

CRAB LOUSE, a sucking louse (*Phthirus pubis*), belonging to the family Phthiridae of the order Anoplura. It is closely related to the head and body lice which attack man. It gets its name from the fact that its feet end in a clawlike structure with which it grasps the hairs of the body so firmly that it is very difficult to dislodge. The crab louse is irregular in outline and only a little longer than wide. It is usually found in the pubic area and is often called the pubic louse. However, it is also found on hair of the chest, armpits, eyebrows, eyelids, and, rarely, upon the head. Crab lice are spread not only by personal contact but also through public toilets—infested individuals scratch them off onto the seats and they infest subsequent users. When numerous they produce a skin irritation called phthiriasis, a condition resulting from their bites. Their presence upon an individual is usually due to ignorance rather than lack of cleanliness. They are small and difficult to see. Until recently it has been difficult to control them, but now a single application of DDT, chlordan, or lindane powder eliminates them. If these are not available sulfur ointment may be used but two or three applications may be necessary.

CHARLES M. CURRAN.

CRAB SPIDER, a medium-sized spider belonging to several arachnid families, the best-known members belonging to the Thomisidae. They get their name from the fact that the anterior two pairs of legs are so modified that they resemble crabs. This adaptation enables them to move sideways with great speed and also provides them with the strength to hold their prey. The crab spiders are essentially hunting spiders. They build no webs and the only silk they spin is, that in which their eggs are en-

closed. Many kinds travel over the ground and bushes to ambush their prey, but species of *Misumena* and related genera conceal themselves in flower heads and capture insects seeking nectar or pollen. See also SPIDERS.

CHARLES M. CURRAN.

CRABB, kräb, George, English lawyer and philologist: b. Palgrave, England, Dec. 8, 1778; d. Hammersmith, Dec. 4, 1851. He studied in Germany and on his return to England published a German reader, grammar, and conversation book which were long in use. In 1829 he was admitted to the bar. His chief works are *Dictionary of English Synonymes* (1816) and *History of English Law* (1829). Among his other works are *Universal Historical Dictionary* (1825) and *New Pantheon or Mythology of All Nations* (1847).

CRABBE, kräb, George, English poet: b. Aldeburgh, Suffolk, England, Dec. 24, 1754; d. Trowbridge, Wiltshire, Feb. 3, 1832. He early showed a passion for reading. After a short time at school he became an assistant to an apothecary and, later, to a surgeon. He contributed verse to *Wheble's Magazine* in 1772. He continued his medical studies in London and returned to Aldeburgh to practice, but in 1780 abandoned medicine and went to London to pursue a literary career. The failure of his work *The Candidate* (1780) left him in financial straits and he appealed for aid to Edmund Burke, who became his patron and arranged for publication of *The Library* (1781). At Burke's suggestion he entered the Anglican ministry. He was chaplain to the duke of Rutland and held several other church livings, including the one at Trowbridge, which he held from 1814 until his death. His works, which were popular in his time, include *The Village* (1783), an object of Samuel Johnson's praise; *The Newspaper* (1785); *The Parish Register* (1807); *The Borough* (1810); *Tales in Verse* (1812); and *Tales of the Hall* (1819). Although he followed the classical convention and wrote mostly in heroic couplets, his works were admired by such Romantics as William Wordsworth, Sir Walter Scott, and Lord Byron. His reputation has declined, but he remains important for his unflinchingly realistic portrayals of the lives of the poor in old East Anglia. He is the subject of one of E. A. Robinson's most memorable poems, *The Children of the Night* (1897). Crabbe's *Works*, 8 vols., with a memoir by his son, first appeared in 1834. Sir Adolphus William Ward edited the *Complete Works*, 3 vols., which were published by the Cambridge University Press in 1905-1907. See PARISH REGISTER, THE.

Consult Ainger, Alfred, *Crabbe* (London 1903); Evans, John H., *The Poems of George Crabbe: a Literary and Historical Study* (New York 1933).

CRABETH, krä-bät', Dirck Pieters and **Wouter Pieters**, Dutch stained-glass painters of the 16th century: b. Gouda, Netherlands; d. there. Dirck's dates are usually given as 1501-1577; Wouter's, as 1509-c.1590. Both traveled in Italy, and Wouter especially was influenced by Raphael. Then each established a glass factory at Gouda. Wouter's paintings are found in France and Italy, but the best work of both brothers is in the Groote Kerk at Gouda, where they painted 13 windows. The nine windows

done by Dirck are more brilliantly colored than those done by Wouter. The finest of those done by Dirck are *Driving the Traders from the Temple*, *The Baptism by John*, and *The Last Supper*. The other windows include *Jonah and the Whale* (Dirck); and *The Queen of Sheba before Solomon*, *The Sacrifice by Elijah before the Priests of Baal*, and *The Sacrilege of Heliodorus* (Wouter). Wouter's work was of wider range than Dirck's, including some portraits and archer groups in the museum at Gouda, and surpassed his brother's in drawing and composition. Portraits of the brothers are in the Groote Kerk. Wouter's grandson, Wouter, was an historical painter.

CRABGRASS, a genus of annual and perennial grasses belonging to the millet tribe. The 50-odd species occur throughout the warmer regions of the world. The Latin name of the genus, *Digitaria*, is an allusion to the characteristic inflorescence, which consists of long, narrow, flower- and seed-bearing racemes radiating from the top of the stem in a digitate or finger-like manner. On account of the form of the inflorescence the plants are sometimes called finger grass. Most of the native North American species (that is, *Digitaria violascens*, *D. serotina*, *D. filiformis*, *D. villosa*, and *D. texana*) are good forage grasses. Some native European and Asiatic species introduced in North America, for example *Digitaria sanguinalis* and *D. ischaemum*, are troublesome weeds in cultivated fields and gardens.

CRABTREE, Lotta (originally CHARLOTTE), American actress: b. New York, N. Y., Nov. 7, 1847; d. Boston, Mass., Sept. 25, 1924. At the age of 10 she played the part of Gertrude in *The Loan of a Lover* at Petaluma, Calif. In 1864 she appeared in New York City in spectacular plays at Niblo's Garden, and first gained a reputation in John Brougham's *Little Nell and the Marchioness*. She soon became a favorite with the American public in pronounced comedy, playing parts especially written for her. Her chief successes were in *Topsy*, *Sam Willoughby*, *Firefly*, *Musette*, *Zip*, *Bob*, *The Little Detective*, and *Nitouche*. She retired from the stage in 1891, having acquired a fortune estimated at several millions of dollars, most of which she left to charity.

CRABTREE, William, English astronomer: b. Broughton, near Manchester, England, 1610; d. place and date unknown. Educated probably at the Manchester grammar school, he engaged in business as a clothier. He early became interested in astronomy, and was able to find defects in the calculations of Continental astronomers. In 1636 he started a correspondence with Jeremiah Horrocks (q.v.), and on Nov. 24, 1639, they were the first to observe the transit of Venus.

CRACKER AND BISCUIT INDUSTRY. Like most of the industries so closely integrated with our daily life it is impossible to establish an exact date for the beginning of the manufacture of biscuits and crackers. The industry includes the manufacture by machines of various crackers and cookies—hard and semihard sweet biscuits made by either cutting, rotary, embossed, bar or wire cut machines. Also included in the industry are the specialized bakers making

ice cream cones, sugar wafers, pretzels, and various toasts. The actual development of the industry as it exists today started with the invention of bakery machines in the middle of the 19th century. However, the development of the process goes back 6,000 years.

Archaeological archives reveal manuscripts and pictures of tools showing the early methods of baking. All baked products were at first in the style of hardtack, large flat sheets of dough made by mixing cracked grain with water. As the knowledge of baking increased new and better ways of grinding, mixing and baking the grain were discovered. The earliest actual record of biscuit manufacture was made by the Pharaohs of Egypt on their tombs: on the walls of a tomb of the 4th dynasty are pictures of shepherds kneading dough in a round stone dish. In the heap of ashes of the fire nearby appear six small cakes. This apparently is the most primitive method of early baking. During the reign of Rameses III a small bakery was established for the use of the royal family. At this time an oven designed like a large conical jar about three feet high and open at the top was used. The fire was prepared inside, flames issuing from the top, and the cakes were baked on the outside of the oven on a little narrow shelf near the top of the jar.

In Babylonia and Assyria baking was done only in the household. No particular trade was established, at least no record can be found of it in the Laws of Hammurabi. An early picture of an Assyrian army camp dated approximately 800 B.C. shows perhaps the earliest view of an oven where the baking was done on the inside and not on the outside, as was the case in Egypt.

In Greece nearly all baking was the work of slave labor, most of it done in bake shops where the Athenian bakers prided themselves on the production of fancy biscuits using wheat, barley or spelt. Early Greek manuscripts mention both unleavened and leavened biscuits as baked on the hearth or in the oven and described as fair-complexioned wheaten cakes.

The first leavening was of course not yeast but sour dough carried over from a previous baking. When used with fresh dough it would give the biscuit a larger volume and a slightly different flavor. The sweetening was honey. Eubulus mentions the twice-baked cake of Greece, undoubtedly something like zwieback.

In Rome, as in Greece, bakers belonged to the slave class. In the 2d century A.C. the Romans developed a large hand mill for grinding wheat. Up to this time all grain had been milled either by mortar and pestle or by rubbing between two stones. Public bakers were quite well known in Rome. At the time of Emperor Augustus, Eury-saces, a baker, had constructed a burial monument to himself using old kneading stones, and around the top appeared a frieze showing all the different processes used in the early bakery. In the excavation of Pompeii, buried by the eruption of Mount Vesuvius (79 A.D.), several public bakers were brought to light. Here we find the use of a fire under the oven, and presume that this type was most extensively used. Formulas of that period contained spices and were rich in cheese, butter, and eggs.

During the Dark Ages when nearly all progress stopped, the art of baking suffered a tremendous blow and throughout Europe we find evidence that bakeries had reverted to

the most primitive form. Out of this period of blackness there began to appear some semblance of order and, after the Norman Conquest of England (1060 A.D.) we find bakers guilds once more forming and carrying forth the advancement of baking. They spread rapidly throughout Italy, France, Germany, and Flanders during the 11th and 12th centuries. In the 13th century we find manuscripts showing that bakers have returned to using large brick ovens, and at the time of the Council of Constance in 1417 bakers were using portable ovens which they could move about the city making pastries and biscuits to order. However, resistance to progress developed in the guilds, leading to the organization of bake shops outside the guilds, and during the first half of the 17th century, as the new bakers began to turn out better work using labor saving devices the guilds lost their hold on the industry.

In 1670 we find the first evidence of mass production trends. There was a form of traveling oven, elongated in design, in which biscuits were placed in long troughs running through the oven; the baker slowly pushed his production along the troughs fast enough for them to bake, placing one cake behind the other, keeping a steady progress of goods traveling through.

Up to this point we find the advancement in the industry exceptionally slow. Milling of the grain was now done by millers entirely, and some bakers were beginning to specialize as the demand for biscuits increased about the middle of the 17th century due to the introduction into western Europe of three new nonalcoholic beverages—chocolate, coffee, and tea. Chocolate not only stimulated the consumption of and demand for light cakes and fancy biscuits but gave the cracker baker a new and very important material and flavor. Cheese and ginger cakes were very popular in the early coffee houses. The English national custom of afternoon tea, so evident in everyday English life, was popularized with the rise of the tea gardens, the most famous of which was perhaps Fox Hall which was started in 1660 and remained in existence under the name of Vauxhall until 1859.

From that time on we find an interest and improvement in bake shops, with a larger variety of ingredients finding their way into the market. Although the advance of the industry had been exceptionally slow, the popularity of biscuits was increasing and bakers began to employ more and more personnel. It must be realized, however, that conditions in England and in Europe were vastly different from those in the United States. Those great countries, being heavily populated, with labor cheap, had no interest in mechanical advancement. In the United States where labor was scarce and population scattered it was necessary to replace manpower with mechanical machinery. The actual development of labor saving machines in the baking industry does not date back much further than 1824, and during the next forty years there was a record of progress little short of miraculous. From 1824 until 1858 there were no less than twenty important developments patented for the industry. Machines for some time did not produce the same quality as did hand work, but as the machines were improved and production became more uniform, and many new designs for quality were developed, the industry broke into two separate classes, that of hand work and of machine work. During this period reel ovens, automatic cutting machines, machine dough

breaks, cooling conveyors, and mechanical mixers were developed.

At the beginning of the 19th century unsweetened and unleavened biscuits were found principally on shipboard where leavened bread could not be kept. For this reason pilot bread, commonly called "hardtack" was in demand in large quantities. When gold was discovered in California cross-country travel required three months and made it impossible to carry bulky food. Consequently every wagon-train made an effort to carry large supplies of biscuits. Then with the Civil War the consumption again vastly increased.

In 1824 Daniel Poole of Baltimore, Md., was granted a patent on a cracker machine. The word "cracker" is a common Teutonic word, in German *krachen* and in Dutch *kraken*, meaning to break with a sharp sound. Thus a cracker when properly baked follows its definition by making a cracking noise as it cools coming from the oven.

Who made the first soda cracker will probably never be known but fermented bread was in general use, and its lack of keeping qualities must have brought about a desire to roll the dough thin and bake it dry so as to make a bread that would keep a long time. Making holes in it to keep it from puffing was merely a mechanical operation and the rubberiness of the younger dough would naturally bring about experimentation leading to longer fermentation that would handle better in forming thin fermented biscuits. As travel became more extensive new varieties of biscuits were found in different parts of the world, and exchanges of formulas between bakers of different areas broadened the manufacturing possibilities and increased sales.

New machinery was introduced in later years such as the chocolate coating machines, the sandwich making machines, carton forming machines, marshmallow depositing machines, icing machines, topping machines, drying equipment, continuous running aprons on cutting machines, ball bearing peeling, panning and embossing machines, new ideas in cutters, new and better types of mixers, continuous marshmallow beaters and many things designed to convey finished goods and bring all plants as near as possible to mechanical perfection and as nearly automatic as possible.

The American biscuit and cracker industry actually started with Theodore Pearson at Newburyport, Mass., in 1792, manufacturing pilot bread, commonly called hardtack. Better known is the name of Josiah Bent who established his water cracker business in 1801, today known as Geo. H. Bent Company of Milton, Mass. Then Smith & Son, Inc., of White River Junction, Vt., started a business in 1815. Alfred Wyman in 1845 opened a cracker plant in Westminster, Mass., which still operates in the original building under the name of Dawley and Shepard. Between that time and 1950 hundreds of plants were started and many failed, while others prospered, and some merged to form such large companies as National Biscuit Company, Sunshine Biscuits, Inc., and United Biscuit Company.

Modern biscuit and cracker plants in 1950 included mixers capable of handling 1,500 pounds of dough at a time, ovens producing 9,000 pounds of finished biscuits per hour, and 300 feet in length. This same progress, so vividly illustrated in American industry, followed throughout Europe as local taxation increased and world commerce became so important. We find that each

CRACKER AND BISCUIT INDUSTRY: Top left: This mixed dough is being dumped to the floor below for baking. Top right: Using machinery of a type that is gradually being replaced by automatic devices, these operators are rolling dough to the proper thickness. Above: Crackers are cut out and stamped from a continuous sheet of rolled dough. Leftover dough, lower right, is returned to hopper and then rolled and stamped again.

National Biscuit Company

 Above left: Finished crackers leave the oven. Above right: Operator regulates flow of crackers through packaging machine

nation has contributed in some respects to the furtherance of the industry. American ingenuity developed many of the mechanical means; English dexterity developed new and improved production methods; national traits and tastes brought macaroons from Italy, sugar wafers from England, and rye-crisp from the Scandinavian countries. In the United States alone the industry grew from \$89,484,000 in 1914 to \$540,222,000 in 1947.

Modernization within the plants also brought many additional changes which have definitely affected the sales of biscuits and crackers, as well as their quality. Among the changes, which the consumer never sees, are the laboratories which conduct research on new materials, and control raw materials and processed goods. Sanitary departments are continually checking the plant and production facilities to insure the purity of the resultant product. Supervisory staffs are technically trained with a background suitable to the responsibility with which they are charged. Among the changes and perhaps the most important to the growth of the industry has been the improvement in packaging methods, keeping pace with the changes in distribution. The familiar cracker barrel of the general store has been replaced first by tins, later cartons, and finally caddies. National Biscuit Company pioneered in producing the first individually wrapped small package which swept the industry during the following years. Bulk sales, representing at first the entire production, in 1950 had declined to a very small percentage. In the large supermarkets the consumer may observe as many as 150 varieties of cookies and crackers on display, representing 6,000 years of advancement in the industry. The latest development in the packaging of biscuits and crackers is the 4-in-1 principle, according to which four individually cellophane wrapped packages are assembled in one carton, providing the housewife with a unit or units which she may open as desired, allowing the remaining packages to stay fresh for future use. The trend is toward providing the consumer with additional packaging protection so that each cookie and cracker, regardless of time and distance from the oven, will taste oven fresh.

The words biscuit, cracker, and cookie have been used by the industry to describe the type or classification into which a product falls. For instance the word biscuits is a term generally used to indicate any of the biscuit and cracker products. English biscuits specifies a type of sweetened product originating in England; under this heading we will find such items as Arrow-root, Nice, and Alberts. Nonsweetened and hard-crisp products such as Sodas and Grahams are referred to as crackers. Cookies are made from soft batters somewhat like cake batter and deposited on pans or on a band oven by means of a depositor.

E. J. VAN ALLSBURG,
Editor, "The Cracker Baker."

CRACKING PETROLEUM. The process in petroleum distillation known as cracking is the subjecting of certain distillation products to a degree of heat so far above their boiling points that they are decomposed into component parts whose boiling points are lower. It is accomplished in an ordinary fire still by condensing vapors arising from the boiling petroleum upon the cool dome of the still, whence they drop into

the superheated oil below, where they are broken up into lighter oils and instantly vaporized, passing over into the condenser. As ordinarily carried on, the process aims to increase the yield of illuminating oil (kerosine) by thus cracking the heavier oils, which distill over immediately after the kerosine vapors have ceased, that is, above the temperature of 625°F. When this temperature is reached the fire under the still is subdued, and the distillation continued slowly up to 700°, during which period the heavier oils dripping back are cracked into gasoline and kerosine. The additional amount of kerosine obtained from the oil is from 18 to 28 per cent. See also PETROLEUM.

The cracking process has more recently been invoked to secure a larger amount of gasoline from crude oil, and from kerosine, to meet the enormous demand for motor fuel. Several processes were invented, or at least patented, almost simultaneously. The Burton process in extensive operation in the United States keeps the entire contents of the still and also of the condenser under a pressure of 60 to 75 pounds to the square inch, through the manipulation of a valve, which is opened occasionally to avoid the liquefaction of the gases in the tubes. The sirupy residue of the distillation is distilled at atmospheric pressure, and its distillate returned to the cracking still. Some crude oils by this process are made to yield as much as 60 per cent in crude gasoline distillate. This is immediately available for use in marine motors, but requires deodorizing for use in automobiles.

The Hall process (American), patented in 1913, met with a warm reception in England and on the Continent, and many large plants are using it. The raw material in this process is common gas oil, and the gasoline yield reaches 70 per cent of "motor spirit," as it is called, having from 18 to 31 per cent more power than ordinary standard gasoline.

In the Rittman process the petroleum vapor is passed into a tube heated to 850°F., under very heavy pressures, ranging up to 500 pounds to the square inch. This vapor is then condensed under pressure, and the resulting liquid distilled for gasoline. The yield is from 60 to 70 per cent of the original bulk of the oil, in small quantities.

Other processes first subject the oil to great heat under heavy pressure, and then distill it; or take the vapors of boiling oil through iron tubes containing a red-hot sponge of some metal; or vary the operation either in the heat and pressure in the still, or in a decomposer, or by some other manipulation, the essential features being heat and pressure. All of these processes are successful to some degree in securing an increased yield of the sought-for gasoline.

CRACOW. See KRAKOW.

CRADDOCK, Charles Egbert, pseudonym.
See MURFREE, MARY NOAILLES.

CRADLE, krá'd'l, in its primary meaning, a baby's bed, usually equipped with rockers or

suspended in some way so the baby may be rocked. The name has also been extended to various kinds of framework suggesting a baby's cradle—the framework that keeps a boat or ship upright while on the ways; that which supports a rigid or semirigid airship during construction, or its car during inflation; the framework supporting a heavy gun; the framework used in building large rafts.

In engraving, a cradle (or rocker) is a sharp-toothed steel tool which is used with a rocking motion to raise burrs on the plate and so lay the ground in mezzotints.

In placer mining, a cradle (or rocker) is a box on rockers which contains a screen with small openings. Material from the deposit is placed on the screen and water is poured over it from a dipper while the cradle is rocked by hand. The water and small particles pass through the screen into the box, where the values (such as gold) are retained, while the water and waste material are discharged over the tailpiece. The cradle is invaluable for sampling placer deposits and may be used exclusively in small-scale placer mining.

In scything, a cradle is an attachment for the scythe, which is furnished with a set of long parallel fingers for catching the hay or grain being mowed and laying it in swaths.

CRADOCK, krăd'ŭk, **STR Christopher** (George Francis Maurice), British naval officer: b. Hartforth, Yorkshire, England, July 2, 1862; d. at sea off Coronel, Chile, Nov. 1, 1914. He entered the navy in 1875, served in the Sudan campaign of 1884, and during the Boxer Rebellion in 1900 distinguished himself at the storming of the Taku forts and participated in the relief of Tientsin. Thereafter he rose by normal stages to the rank of rear admiral (1910), becoming a Knight Commander of the Victorian Order in 1912. His *Whispers from the Fleet*, addressed chiefly to young naval officers, was published in 1907.

In February 1913, Cradock was given command of the North America and West Indies station, and on the outbreak of World War I had the responsibility of keeping the trade lanes free of German raiders. In September 1914, he undertook similar operations in the South Atlantic, at a time when Vice Admiral Maximilian von Spee, commander of the German Far Eastern Squadron, was known to be moving eastward across the Pacific with five cruisers superior in speed, armor, and gun power to Cradock's force of three cruisers, an armed merchantman, and an old, slow battleship.

Cradock's urgent request for reinforcements was refused by the Admiralty, which issued ambiguous orders that Cradock interpreted to mean he was to seek out von Spee and fight. He therefore rounded Cape Horn. New orders belatedly sent by the Admiralty, clarifying his instructions and informing him that reinforcements were being sent, never reached Cradock, who left the battleship behind to increase his squadron's speed in the search and engaged von Spee off Coronel, 15 miles south of Concepción, Chile. The Germans' superiority and von Spee's skillful use of it won them a quick victory, in which Cradock went down with his flagship, the *Good Hope*. Von Spee's squadron was destroyed in the Battle of the Falkland Islands in December. See also **WAR, EUROPEAN—Naval Operations**.

CRAFTS, kräfts, **James Mason**, American organic chemist: b. Boston, Mass., March 8, 1839; d. Ridgefield, Conn., June 20, 1917. He graduated from Lawrence Scientific School, Harvard, in 1858, and in 1860 went to Germany to continue his studies at the Bergakademie in Freiberg and at the University of Heidelberg, where for a year he was an assistant to Robert Wilhelm Bunsen. In 1861, Crafts moved to Paris to study under Charles Adolphe Wurtz and here he met Charles Friedel, with whom he later carried out some of his most brilliant researches.

Crafts returned to the United States in 1865 and after investigating mines in Mexico, 1866–1867, he became professor of chemistry at Cornell, 1868–1871, and then at the Massachusetts Institute of Technology, 1871–1874. Ill health forced his retirement from teaching and in 1874 he joined Friedel in Paris to devote himself to research, mainly in the field of organic chemistry.

Crafts made important contributions to thermometry and the determination of vapor densities, but his most fruitful achievement was his discovery with Friedel of the so-called Friedel-Crafts reaction, by which hundreds of new carbon compounds have been brought into existence.

In 1891, Crafts returned to the United States. He was professor of organic chemistry at the Massachusetts Institute of Technology from 1892 to 1897, and became president of the institute in 1898, resigning the presidency in 1900 to resume teaching and conduct research in thermometry and catalysis in concentrated solutions. Besides innumerable scientific papers, Crafts published *Qualitative Chemical Analysis* (1870), *Studies in Thermometry* (1880), *Catalysis in Concentrated Solutions* (1908), and *Thermometry* (1913–1915).

CRAG MARTIN or **ROCK SWALLOW**, a swallow (*Hirundo rupestris*) allied to the barn swallow. It is found from central Europe, the Mediterranean region, and northwestern Africa, eastward to China and Manchuria, the northern populations migrating to India and to Egypt and northeastern Africa in the winter. It frequents rocky cliffs along river banks and in mountainous areas, and builds a large open-topped nest of mud

Crag martin.

in niches of the rocks, or occasionally on the timbers of buildings or among ruins. The general color of the bird is ashy brown above, the lower parts creamy buff. The tail feathers are conspicuously spotted with white. A very similar species, the pale crag martin (*H. obsoleta*), occurs in some of the more arid parts of the range of the crag martin.

DEAN AMADON.

CRAIG

CRAIG, kräg, Charles Franklin, American bacteriologist and army officer: b. Danbury, Conn., July 4, 1872. He graduated from the Yale Medical College in 1894 and entered the army as an acting assistant surgeon in 1898. From that year until 1906 he served as a pathologist and bacteriologist in army hospitals in the United States, Havana, and Manila. He then became assistant professor of bacteriology and clinical diagnosis in the Army Medical School at Washington, 1909-1913, and from 1913 to 1918 he was the commanding officer of army laboratories at Fort Leavenworth, Kans., and El Paso, Texas. He was promoted to the rank of colonel in 1918.

Subsequently Craig served as professor and director of laboratories in the Army Medical School, 1920-1922; medical inspector of the Hawaiian Department, 1922-1926; and commandant and director of clinical pathology and preventive medicine at the Army Medical School, 1926-1930. He was professor of tropical medicine at Tulane University from 1931 to 1938.

Craig is known particularly for his studies of dengue and of *Plasmodium ovale* in malaria, and for his development of a new technique for the Wassermann test and a diagnostic test for amebiasis. Among his writings are *The Acute-Autumnal Malarial Fevers* (1901); *The Parasitic Amoebae of Man* (1911); *The Wassermann Test* (1918); *Amebiasis and Amebic Dysentery* (1935); *Clinical Parasitology*, with Ernest Carroll Faust (1937); *The Laboratory Diagnosis of Protozoan Diseases* (1941); and *The Etiology, Diagnosis and Treatment of Amebiasis* (1944).

CRAIG, Edward Gordon, English stage designer, actor, and producer: b. Harpenden, Hertfordshire, England, Jan. 16, 1872. The son of Ellen Terry and Edward William Godwin, he made his first stage appearances in London in 1878 and at Chicago in 1885, and his adult debut under Sir Henry Irving in London in 1889, with his mother in *The Dead Heart*. Craig continued with Irving, playing many Shakespearean roles, until 1897. He then left the stage to study drawing and wood engraving, publishing his woodcuts in *The Page* (1898-1901), but soon turned to stage design. From the start his work in this field assumed importance for the future of the theater.

He produced Henry Purcell's *Dido and Aeneas* in 1900 and George Frederick Handel's *Acis and Galatea* in 1902; followed in 1903 by Henrik Ibsen's *Vikings at Helgeland* (*Warriors at Helgoland*), with Ellen Terry in the lead, and Shakespeare's *Much Ado About Nothing*; a German version of Thomas Otway's *Venice Preserved* (Berlin 1904); designs for the production of *Electra* with Eleanor Duse in 1905; and Ibsen's *Rosmersholm* with Duse (Florence, Italy, 1906). Later productions included *Hamlet* for the Moscow Art Theatre in 1912 and a gala presentation of Ibsen's *Pretenders* at Copenhagen in 1926.

The keynote of Craig's designs is simplicity, a stage "cleared for acting," and the use of color and controlled light to create imaginative, symbolic, poetic effects. Like the achievement of Adolphe Appia (1862-1928) in Germany—above all in lighting—his work stands in sharp contrast to the cluttered sets of "photographically realistic" stage design. Not infrequently Craig's designs are difficult to adapt to existing theater architecture, however, and thus when seen in the theater are necessarily compromises.

Craig edited *The Mask*, a magazine devoted to theatrical masks, published from 1908 to 1929 in Florence, where he conducted his School for the Arts of the Theatre, founded in 1913. His publications include *The Art of the Theatre* (1905), *Towards a New Theatre* (1913), *The Theatre Advancing* (1921), *Scene* (1923), *Henry Irving* (1930), and *Ellen Terry and Her Secret Self* (1931).

Consult Rose, Enid, *Gordon Craig and the Theatre* (New York 1932).

CRAIG, James. See CRAIGAVON, 1ST Viscount.

CRAIG, Sir James Henry, British soldier and governor general of Canada: b. Gibraltar, 1748; d. London, England, Jan. 12, 1812. He entered the army in 1763 and in 1771 became captain of the 47th Regiment, which he accompanied to America in 1774 on the eve of the revolution. Craig was wounded at the Battle of Bunker Hill, and in 1776 with his regiment helped to repel the American invasion of Canada. The next year he distinguished himself in the early part of Gen. John Burgoyne's invasion of the Hudson River valley from Canada and was sent home with dispatches, thus escaping the fate of Burgoyne's army. In 1781 he fought under Gen. Charles Cornwallis in North Carolina and was promoted lieutenant colonel.

Craig took part in the disastrous expedition against the French in the Netherlands in 1794 as adjutant general to the duke of York's army. He was then given command of the troops sent from England with the fleet of Vice Admiral George Keith Elphinstone, which in cooperation with an army under Maj. Gen. Alured Clarke captured the Dutch colony at the Cape of Good Hope in 1795. Craig served as temporary governor of this colony until 1797, when he was made a Knight Commander of the Bath. Subsequently he held commands in India (to 1802) and England (to 1805), being promoted lieutenant general in 1801. On the outbreak of the War of the Third Coalition against Napoleon in 1805, Craig was sent to the Kingdom of Naples in command of 7,300 troops to join a Russian army of some 13,000 men under Gen. Maurice Lacy in a northward movement against the flank of Napoleon's army; but upon receiving news of Napoleon's shattering victory at Austerlitz, he abandoned the indefensible Italian mainland for Sicily, which was thenceforth a bastion of British strength in the Mediterranean. Ill health forced his return to England in 1806.

On Aug. 29, 1807, Craig was appointed governor general of Canada, a position for which he was ill-suited because of his temperament, lack of experience, and the precarious condition of his health. He reached Quebec on Oct. 18, 1807, and almost at once fell under the influence of the governing clique. Persuaded that French Canadian separatism implied disloyalty, he followed a repressive policy and undertook a long struggle with the Assembly of Lower Canada. This contest, in which his opponents were led by Jean Antoine Panet, speaker of the Assembly, and the bishop of Quebec, Joseph Octave Plessis, culminated in the arbitrary imprisonment of several members of the Assembly and the closing of the French Canadian journal *Le Canadien*. Pierre Bédard and others connected with *Le Canadien* were also imprisoned.

Craig resigned his office in October 1811 and returned to England, where he was promoted general in January 1812, shortly before his death. The conciliatory policy of his successor, Sir George Prevost, undid the damage of Craig's administration in time to unite Canadians against invasion by the United States during the War of 1812.

CRAIG, John, Scottish religious reformer: b. Aberdeenshire, Scotland, about 1512; d. Scotland, Dec. 12, 1600. He entered the Dominican Order some two years after completing his education at St. Andrews, but before long he was imprisoned on suspicion of heresy. Upon his release he went to England, in 1536, and from there to Rome, where through the influence of Reginald Cardinal Pole he was made master of novices in the Dominican monastery at Bologna, of which he later became rector. A chance reading of John Calvin's *Institutes of the Christian Religion* strengthened Craig's Protestant leanings. When this became known he was sent to the prison of the Inquisition at Rome. Condemned to the stake, he escaped—apparently when the mob broke open the prison on the death of Pope Paul IV in 1559—and ultimately reached Vienna, where he obtained the favor of the Archduke Maximilian (later the Emperor Maximilian II). Pope Pius IV sought his return as a heretic, but Maximilian provided for Craig's safe return to England in 1560.

Upon his return to Scotland, Craig became a preacher in the reformed church and in 1563 was appointed the colleague of John Knox in his church at Edinburgh. He is perhaps best known for his bold refusal, in 1567, to publish the banns for the marriage of James Hepburn, earl of Bothwell, to Mary, queen of Scots, after the murder of her previous husband, Lord Darnley—although Craig later complied under protest. During the years 1572 to 1579, he preached and taught at Montrose and Aberdeen, returning to Edinburgh in 1579 as chaplain to the young James VI. He took a leading part in church affairs, usually as a moderate following a middle course between the two extreme parties. Craig participated in the composition of the *Second Book of Discipline* and the National Covenant of 1580, and in 1581 wrote *Ane Shorte and Generale Confession of the True Christian Fayth and Religion, According to God's Worde and Actes of Our Parliamantes*, which was signed by the king and his household—hence called the King's Covenant—and became the basis of the National Covenant of 1638 and the Solemn League and Covenant of 1643, both of major importance in the religious history of Scotland.

CRAIG, Malin, United States army officer: b. St. Joseph, Mo., Aug. 5, 1875; d. Washington, D.C., July 25, 1945. He graduated from the United States Military Academy in 1898 and served in the Santiago (Cuba) campaign in that year during the war with Spain. Craig served in China in the Boxer Rebellion (1900), subsequently in the Philippines, and in France from 1917 to 1919. After World War I he was given commands in the United States, the Philippines, and the Panama Canal Zone, being promoted brigadier general in 1921 and major general in 1924. Craig served as army chief of staff with the rank of general from Oct. 2, 1935, to Aug. 31, 1939, when he retired. During World War II he was

recalled to duty as head of the Personnel Board of the War Department from 1941 to 1945.

CRAIG, Sir Thomas, Scottish jurist: b. Scotland, 1538?; d. there, Feb. 26, 1608. He was educated at St. Andrews and the University of Paris (1555–1561), and from 1564 to 1573 was justice depute (deputy) of Scotland, presiding over criminal trials. An adherent of James VI (James I of Great Britain from 1603), Craig was one of the Scottish commissioners appointed to confer on the projected union with England in 1604.

He was the author of many poems in Latin (including an epithalamium on the marriage of Mary, queen of Scots, and Lord Darnley in 1565) and of the following works, also written in Latin: *Ius Feudale*, his most important work published in 1603, demonstrating the common origin of Scottish and English feudal law; *Treatise on the Right of James VI to the Succession to the English Crown*; *Treatise on the Union* written about 1604; and *De Hominio*, a patriotic work written in 1605, contending that Scotland had never paid homage to English rulers except during the brief periods of English conquest.

CRAIG, William James, British Shakespearean editor: b. County Derry, Ireland, Nov. 6, 1843; d. London, England, Dec. 12, 1906. He was educated at Trinity College, Dublin, graduating M.A. in 1870. From 1874 to 1898 he was a tutor in London, except for the years 1876 to 1879, when he was professor of English language and literature at University College Aberystwyth, Wales. Craig edited the one volume *Oxford Shakespeare* (1894), and after 1898 he devoted himself to research and to editing *The Little Quarto Shakespeare* (40 vols. 1901–1904). He was general editor of the *Arden Shakespeare* from 1901 until his death.

CRAIGAVON, kräg-äv'un, 1st Viscount (JAMES CRAIG), a statesman of Northern Ireland: b. Sydenham, suburb of Belfast, Ireland Jan. 8, 1871; d. Glencairn, County Down, Northern Ireland, Nov. 24, 1940. He served with the British Army in South Africa in 1900–1902, and in 1906 was elected member of Parliament for East Down, Ulster. Craig held this seat until 1918, when he was elected member of Parliament for Mid-Down, 1918–1921. During this period Craig became Edward Carson's chief lieutenant in the Unionist agitation against the Home Rule Bill, which would have placed all Ireland, including Protestant Ulster, under a parliament at Dublin, thus breaking the ties with London.

While Carson led the Unionists in Parliament, Craig concentrated his efforts in Ulster, where a provisional government was made ready and the Ulster Volunteer Force was raised for armed resistance to a union with southern Ireland. The impending civil war was averted by the outbreak of World War I, and Craig served with the Ulster Volunteer Force (renamed the Ulster Division) in France, 1914–1915. Following the peaceful solution of the home rule question in 1920–1921, Craig resigned his seat at Westminster to enter the Parliament of Northern Ireland and become its first prime minister. He held this office from 1921 until his death, when he left the new state on a firm foundation. Craig was created a baronet in 1918, and Viscount Craigavon in 1927.

CRAIGIE, krä'gī, Pearl Mary Teresa (nee RICHARDS; pen name JOHN OLIVER HOBBS, höbz), English author: b. Chelsea, near Boston, Mass., Nov. 3, 1867; d. London, England, Aug. 13, 1906. She was born Pearl Richards, the daughter of a New York merchant who moved his family to London in 1868. London was thenceforth her home. In 1887 she married Reginald Walpole Craigie, but the marriage was unhappy and ended in divorce in 1895. She adopted the Christian names Mary Teresa on her conversion to Roman Catholicism in 1892.

Mrs. Craigie was a curious combination of religious mystic and worldly-wise member of fashionable London society. She began writing while still a girl and had her first considerable success with her first and second novels, *Some Emotions and a Moral* (1891) and *The Sinner's Comedy* (1892). These and her later works appeared under her pseudonym. Other novels, of which *The Herb Moon* (1896) is perhaps the best known, were comparative failures with the public. Between 1894 and 1904 she wrote several plays, of which *The Ambassador* (produced in 1898) and *The Bishop's Move*, written in collaboration with Murray Carson and produced in 1902, were well received. At its most successful, Mrs. Craigie's fictional work shows an acute observation of contemporary social life, sprinkled with epigrams; a glittering surface which does not always compensate for the slenderness of plot and characterization or the elusiveness of her ideas.

CRAIGIE, SIR William Alexander, Scottish philologist and lexicographer: b. Dundee, Scotland, Aug. 13, 1867. Educated at St. Andrews, 1883-1888, and at Oxford, 1889-1892, he studied Scandinavian languages in Copenhagen, 1892-1893, and returned to St. Andrews as lecturer, 1893-1897. In the last-named year he joined the staff working on the *Oxford English Dictionary*, of which he was joint editor from 1901 to 1933. Craigie was lecturer in Scandinavian languages at the Taylor Institution, Oxford, from 1905 to 1916, professor of Anglo-Saxon at Oxford, 1916-1925, and professor of English at the University of Chicago from 1925 to 1935. At Chicago he was coeditor, with James R. Hulbert, of *A Dictionary of American English on Historical Principles*, published in four volumes in 1938-1944. He was knighted in 1928.

Craigie was also the editor of *A Dictionary of the Older Scottish Tongue* (1931-) and edited a number of Scottish texts. Among his works on Scandinavian, Anglo-Saxon, and English subjects are: *The Religion of Ancient Scandinavia* (1906); *Skotlands Rimur* (1908); *The Icelandic Sagas* (1913); *Easy Readings in Anglo-Saxon* (1923); *Specimens of Anglo-Saxon Prose and Poetry* (1923-1931); *Easy Readings in Old Icelandic* (1924); *The Study of American English* (1927); *The Northern Element in English Literature* (1933); *The Art of Poetry in Iceland* (1937); *Specimens of Icelandic Rimur* (1952).

CRAIK, kräk, Dinah Maria (nee MULOCK and best known as Miss MULOCK, mü'lök), English author: b. near Stoke-upon-Trent, Staffordshire, England, April 20, 1826; d. near Bromley, Kent, Oct. 12, 1887. She was the daughter of a clergyman, who moved his family to London in 1839. She began as a writer of stories for children. Later works in this field, especially *The*

Fairy Book (1863), *The Adventures of a Brownie as Told to My Child* (1872), and *The Little Lamc Prince* (1874), were widely read, but her first success came with the appearance of her novel *The Ogilvies* in 1849. After writing several more novels, in 1856 she published her best known work, *John Halifax, Gentleman* (q.v.), which was followed by *A Life for a Life* (1859) and many others. She was also noted for her essays *Sermons out of Church* (1875) and *Plain Speaking* (1882), and wrote other poems, tales, and travel books. Her fiction is habitually optimistic in tone and frankly didactic. Modern readers are likely to find most of it kindly and pious but dull. Miss Mulock married the publisher George Lillie Craik in 1864.

CRAIK, James, American physician: b. Arbigland, near Dumfries, Scotland, 1730; d. Fairfax County, Va., Feb. 6, 1814. His father, William Craik, owner of the estate of Arbigland, had as gardener the father of John Paul Jones. The younger Craik studied medicine at the University of Edinburgh and in 1750 crossed the Atlantic, practicing in the West Indies and at Norfolk and Winchester in Virginia. On March 7, 1754, he was commissioned an army surgeon and in the next year he accompanied Gen. Edward Braddock's disastrous expedition against Fort Duquesne. When, later in 1755, Washington was appointed commander in chief of the Virginia forces, Craik became his chief medical officer.

A close friend of Washington, Craik played a prominent part in exposing the plot of the "Conway Cabal" to remove Washington from command during the American Revolution. In 1780 he organized hospitals for the comte de Rochambeau's army on its arrival at Newport, R. I. Craik was chief physician and surgeon of the army from 1781 to 1783, and physician general, 1798-1800, when there was a threat of war with France. He attended Washington in his last illness, concerning which he and Dr. Elisha Dick wrote a report. Washington bequeathed him a bureau and a chair from his study.

CRAIOVA, Krä-yö'vä (also spelled KRAJOVA), administrative region, Rumania, formed in 1952. The region, which is part of the great Rumanian grain and livestock district, lies in the southwest, between the Danube River in the south and the Transylvanian Alps in the north. The main centers, in addition to Craiova, the capital, are Turnu-Severin, near the Danube's Iron Gate, and the Danube River port of Calafat opposite Vidin, Bulgaria. Area about 6,000 square miles; pop. (1952 est.) 1,480,000.

CRAIOVA, Krä-yö'vä (also KRAJOVA), city, Rumania, on the Jiu (or Jiul) River, about 120 miles west-southwest of Bucharest. It became the capital of the Craiova Region under the Rumanian Constitution of 1952. Situated on the Bucharest-Budapest railway, in an upland region of grainland, pasture, and forest, Craiova is the commercial and industrial center of the district of southwest Rumania known as Oltenia or Little Walachia. The city is an important grain market and manufactures textiles, machinery, ceramics, cordage, leather goods, and foodstuffs.

Craiova, presumably founded on a Roman settlement, had become an important center of trade

the two most serious in New Jersey; bitter rot, fruit rot, and end rot are the three most serious in Massachusetts; and late rot is the most serious in Wisconsin and on the Pacific coast. Fermate, Karbam, and Karbam White have been found the most effective sprays in their control. Rose bloom is a fungus disease causing enlarged rose-colored shoots; it is controlled by spraying with bordeaux mixture. False blossom, the most serious of all diseases, is a virus disease producing a witches-broom development of the plant. It also stops fruit production. It is spread by the blunt-nosed leafhopper and is controlled by controlling the leafhopper with a 5 per cent DDT dust, a pyrethrum dust, or dusts containing rotenone.

Aside from the leafhopper, the root grub, fruitworm, fireworm, gypsy moth, and the girdler are the most serious insect pests. The root grubs are estimated to reduce the crop in Massachusetts alone by 150,000 barrels annually. Flooding until midsummer is considered the best control. The fruit worm may take one-third of the entire crop in some years; it is controlled by spraying or dusting in the blossoming period with derris or cryolite. Growers become expert in insect control.

Weed control is a major part of cranberry production. Many weeds, such as grasses, sedges, and rushes are controlled by spraying with water-white kerosene at 300 to 600 gal. per acre about the second week in May. Various other materials are used for other weeds.

Besides *O. macrocarpus* there are several other species of cranberries, none of which are cultivated. One, *V. vitis idaea*, is extensively harvested in northern Europe, northern Asia, and to a lesser extent in northern North America in the wild, and is used in commerce about as is the cranberry of this country. It is known by scores of common names. It is commonly called the European cranberry in this country, the "mountain cranberry" in New England, "foxberry" in Nova Scotia, "partridge berry" in Newfoundland, "cowberry" and "foxberry" in England, "tyttebaer" in Norway, Denmark, and Germany, "lingonberry" or "kroesa" berry in Sweden and Finland, and "preusselbeere" in Germany. It is represented in this country by a variety "minor," smaller in plant and fruit than the form found in Europe, which is shipped into this country from Canada. The European form is used much more commonly in the countries to which it is native than is the American cranberry in this country; and it is preserved by the housewives in great quantities. The berries ripen from August to October, are smaller than the American cranberry, and grow in clusters at the end of the shoot. They are gathered chiefly by hand but also with miniature scoops. They are sold on the fresh fruit market, and dried, are preserved, and the juice is packaged to be used in fruit soups. So far as known, it has not been crossed with the American cranberry.

The other species of cranberry are *O. quadripetalus* and *O. macrocarpus*. Both are commonly called "mossberries." They are circumpolar and are usually found growing on sphagnum moss. Though both are harvested for home use, they are rarely as abundant as the European cranberry and the cultivated species. *O. quadripetalus* is a tetraploid form in the United States while *O. macrocarpus*, the diploid form, is found in Alaska and British Columbia. Recently the chromosome number of the culti-

vated cranberry has been doubled by artificial means, and crosses have been made with the tetraploid *quadripetalus*.

The highbush cranberry, cranberry bush, or pembina is not a cranberry but a native American shrub, *Viburnum trilobum*, which commonly grows 6 to 12 feet high and bears clusters of very acid scarlet berries which are used for jelly. The European species, *V. opulus*, has bitter inedible berries.

GEORGE M. DARROW,
Principal Horticulturist, United States Department of Agriculture.

CRANBROOK, Gathorne Gathorne-Hardy, 1st EARL, English statesman; b. Bradford, Oct. 1, 1814; d. Hemsted Park, Oct. 30, 1906. In 1865 he defeated Mr. Gladstone in the celebrated Oxford University election; in 1878 he was raised to the peerage as Viscount Cranbrook. He was under secretary of state for the Home Department (1858–1859), president of the Poor-law Board (1866–1867), home secretary (1867–1868), war secretary (1874–1878), secretary of state for India (1878–1880) and lord president of the council (1885, 1886–1892).

CRANBROOK, Canada, town of British Columbia, in the Kootenay Valley between the Selkirk and Rocky mountains, on the Canadian Pacific Railroad, 35 miles west of Fernie. It contains the provincial buildings, a high school, manual training school, several primary schools and churches. It has extensive agricultural and mining interests and is an important trade center. Its manufactures include brick yards, mineral water works, iron foundries, planing mills and sash and door factories. Pop. (1931) 3,067.

CRANCH, Christopher Pearse, American artist and poet; b. Alexandria, Va., March 8, 1813; d. Cambridge, Mass., Jan. 20, 1892. He was a son of William Cranch (q.v.). He studied at Columbian University, Washington, D.C.; was graduated at the Harvard Divinity School 1835; preached in Unitarian pulpits for a few years, and then gave himself up entirely to painting and poetry. He studied in Italy 1846–1848, 1853–1863, when he returned to America and was elected a member of the National Academy, but exhibited nothing after 1871. He was an intimate friend of Lowell and Longfellow; a man of versatile if not commanding talent; and one whose friendship was highly cherished by the few favored with it. Some of the best known of his paintings are *Val de Moline, Amalfi, Italy* (1869); *Venice* (1870); and *Venetian Fishing Boats* (1871). His well-known poem *Thought* appeared in *The Dial* (1840). His published works include *Poems* (1844); *Salan: a Libretto* (1874); *The Bird and the Bell, and Other Poems* (1875); *Ariel and Caliban* (1887).

CRANCH, William, American jurist; b. Weymouth, Mass., July 17, 1769; d. Washington, D.C., Sept. 1, 1855. He was graduated at Harvard in 1787; admitted to the bar in 1790; appointed an associate judge of the United States Circuit Court for the District of Columbia in 1801; and chief justice of that court in 1805.

CRANDALL, Prudence, American school-teacher: b. Hopkinton, R. I., Sept. 3, 1803; d. Elk Falls, Kans., Jan. 28, 1889. Of Quaker descent, she opened a school for girls at Canterbury, Conn., in 1831. She admitted a Negro pupil, whom she declined to dismiss despite the protests of the townspeople. The white pupils were then withdrawn from the school, and Miss Crandall decided to teach only Negroes. In 1833, as the new school was about to open, a town meeting was held to protest her action, and when this failed to dissuade her, her opponents influenced the state legislature to pass a law making it illegal to establish a school for Negroes not resident in the state unless the town in which the school was to be situated consented. Arrested and imprisoned under this law, Miss Crandall was brought to trial. Her case was espoused by noted abolitionists, who engaged counsel to defend her, and a newspaper, the *Unionist*, was founded in Brooklyn, Conn., to plead her cause. The jury disagreed, and a second trial was held, resulting in Miss Crandall's conviction. She appealed to the state supreme court, which reversed the judgment (1834). During the two years' struggle with the town, she had been subjected to threats and persecution, and she decided that it would be impossible to continue to operate a school there. Shortly thereafter, she married the Rev. Calvin Philleo and moved to Illinois. In 1874 she went to Kansas, where she spent the remainder of her life.

CRANE, (Robert) Bruce, American landscape painter: b. New York, N. Y., Oct. 17, 1857; d. Bronxville, N. Y., Oct. 29, 1937. He studied art in New York, where he was a pupil of Alexander H. Wyant, and in Paris, and held his first exhibition at the National Academy of Design in 1879. During his career he received numerous honors, including gold medals from the academy (1901 and 1912), the Webb Prize of the Society of American Artists (1897), and the bronze medal of the Carnegie Institute (1909), as well as medals at all the principal expositions. He became a member of the National Academy in 1902.

Among Crane's paintings are *March*, in the Brooklyn Museum; *Autumn Uplands*, in the Metropolitan Museum of Art; *Springtime*, in the Peabody Institute, Baltimore; *November Hills*, in the Carnegie Institute, Pittsburgh; *Autumn*, in the National Collection of Fine Arts, Washington; and *November Hillside*, in the Corcoran Gallery of Art, Washington.

CRANE, (Harold) Hart, American poet: b. Garrettsville, Ohio, July 21, 1899; d. at sea, April 27, 1932. Brought up mainly in Cleveland, he began writing verse at the age of 13. He traveled to Cuba and France; worked in a munitions plant and a shipyard in World War I, and later as a book clerk, reporter, and writer of advertising copy. Early in his twenties he moved to New York, where, with the aid of the banker-philanthropist Otto H. Kahn, he completed *The Bridge* (1930), a series of poems about the United States inspired by the Brooklyn Bridge. In 1930 he won the Helen Haire Levinson Prize awarded by *Poetry: A Magazine of Verse*, and in the following year was awarded a John Simon Guggenheim fellowship.

His brief career was marked by progressive personal disintegration until, while returning by

ship from Mexico to New York, he jumped or fell overboard. In his poetry, Crane has been accused of practicing the cult of unintelligibility, and as vehemently defended. He himself admitted that he was more interested in the psychological impingement of words on the consciousness than in their "rigid" logical meanings. Besides *The Bridge*, his books include *White Buildings* (1926) and *Collected Poems* (1933).

CRANE, Ichabod, the superstitious Yankee schoolmaster in Washington Irving's *Legend of Sleepy Hollow*, in *The Sketch Book* (1820), who was frightened away from the Hollow by his adventure with the Galloping Hessian, and so lost Katrina Van Tassel to his rival.

CRANE, Stephen, American writer: b. Newark, N. J., Nov. 1, 1871; d. Badenweiler, Germany, June 5, 1900. He attended Lafayette College and Syracuse University, but his mother's death in 1890 cut short his education. Moving to New York, he led a hand-to-mouth existence for five years as a free-lance writer for the *Tribune* and the *Herald*. He knew hunger and illness, and with the clear eyes of a reporter saw the life of derelicts in a great city. Out of this inner and outer turmoil came his first book, *Maggie: A Girl of the Streets* (issued by himself in 1892), which, though immature and a failure, was later to be called "the earliest of American realistic novels." The same extraordinary vividness and intensity characterized his masterpiece, *The Red Badge of Courage*, finished before he was 23 and published in 1895. Crane evoked the clamor and terror of death on the battlefield, creating an impressionistic picture of ordinary soldiers in the Civil War that perhaps no factual account could render. The book struck a new note in descriptive writing and made Crane famous, though it earned him little.

In 1896 he joined a filibustering expedition to Cuba. Out of his experiences when his ship was wrecked off the coast of Florida came his most famous short piece, *The Open Boat*, considered one of the finest stories in English. He was a war correspondent in Greece in 1897 and in Cuba, during the Spanish-American War, in 1898. His last year was spent in England, which he left just before his death from tuberculosis.

Besides other novels and two volumes of verse, *The Black Riders and Other Lines* (1895) and *War Is Kind* (1899), Crane wrote numerous sketches and short stories, some about children, others colorful tales of adventure in the West and Mexico. Much of his best-known writing is gathered in *Men, Women and Boats* (1921). *The Works of Stephen Crane*, in 12 volumes, edited by Wilson Follett, was published in 1925-1926. See also RED BADGE OF COURAGE, THE.

J., 1923); Starratt, Vincent, *Stephen Crane: A Bibliography* (Philadelphia 1923); Berryman, John, *Stephen Crane, American Men of Letters Series* (New York 1950); valuable material collected by the Stephen Crane Association of Newark, N. J.

CRANE, Thomas Frederick, American teacher and scholar: b. New York, N. Y., July 12, 1844; d. De Land, Fla., Dec. 9, 1927. He was educated at the College of New Jersey (now Princeton University), from which he received his B.A. degree in 1864, his M.A. in 1867, and his Ph.D. in 1883. After studying law, he was ad-

mitted to the New York bar in 1866, but practiced for only two years before he joined the faculty of the newly founded Cornell University as assistant professor of Spanish and German. He became a full professor in 1873, professor of Romance languages in 1882, dean of the college of arts in 1896, and dean of the university faculty in 1902, retiring as professor emeritus in 1909. In 1898-1899 and again in 1912-1913 he served as acting president of the university. Crane did pioneer research in folklore and medieval literature. His published works include *Mediaeval Sermon-Books and Stories* (1883); *Italian Popular Tales* (1885); an edition of *The Exempla, or Illustrative Stories from the Sermones Vulgares of Jacques de Vitry* (1890); *Mediaeval Sermon-Books and Stories and Their Study Since 1883* (1917); *Italian Social Customs of the 16th Century* (1920); and an edition of *Liber de Miraculis Sanctae Dei Genitricis Mariae, Published at Vienna, in 1731 by P. Pes* (1925).

CRANE, Walter, English painter and illustrator: b. Liverpool, England, Aug. 15, 1845; d. Horsham, March 14, 1915. The son of Thomas Crane (1808-1859), portrait painter and miniaturist, he was apprenticed in 1859 to the wood engraver William James Linton (q.v.), in whose employ he became acquainted with the works of the Pre-Raphaelites. He soon began to illustrate books and paint pictures, and became associated with William Morris in the movement to reform British decorative art and in the advocacy of socialism. He served as president of the Arts and Crafts Exhibition Society (1888-1890; 1895-1915), director of design at the Manchester Municipal School of Art (1893-1896), and principal of the Royal College of Art (1898-1899). Among the books which he illustrated are *The New Forest* (1863); *The Baby's Opera* (1877); *Household Stories from Grimm* (1882), in which *The Goose Girl*, from which Morris wove a tapestry, appears; *The Sirens Three* (1886), a volume of his own poems; *Flora's Feast, a Masque of Flowers* (1888); *Queen Summer* (1891); *Renaissance* (1891); and *Spenser's Faerie Queene* (12 parts, 1894-1896), his masterpiece. He also wrote a number of books, including *The Bases of Design* (1898); *Line and Form* (1900); and *An Artist's Reminiscences* (1907). His pictures include *The Renaissance of Venus* (1877); *The Bridge of Life* (1884); *The Mower* (1891); and *Neptune* (1893).

CRANE, William Henry, American actor: b. Leicester, Mass., April 30, 1845; d. Los Angeles, Calif., March 7, 1928. He made his professional debut in 1863 with the Holman Opera and Dramatic Troup in Utica, N. Y., and remained with that company until 1870, when he joined the Oates Opera Company. At first a singer, he soon discovered that he had a natural talent for comedy. In 1874 he became a member of R. M. Hooley's stock company in Chicago, and three years later went to New York, where, with Stuart Robson, he enjoyed his first marked success in *Our Boarding House*. The two actors appeared together in a number of Shakespearean roles and, in 1889, in *The Henrietta* by Bronson Howard, their greatest success. Crane starred alone in *The Senator* (1889); *On Probation* (1890); *A Virginia Courtship* (1898); *David Harum* (1900-1903); in which he gave his most notable portrayal; *Business Is Business* (1906);

Father and the Boys (1907-1910); *The Senator Keeps House* (1911); and *The New Henrietta* (1914). After retiring from the legitimate stage in 1916, he played for a year in vaudeville, and later appeared in motion pictures.

CRANE, Winthrop Murray, American manufacturer: b. Dalton, Mass., April 23, 1853; d. there, Oct. 2, 1920. From 1870 he was employed by the Crane Company, his family's paper-manufacturing business, for which he secured the contract to supply paper for United States notes. He was a member of the Republican National Committee from 1892 to 1900 and from 1904 until his death. From 1897 to 1899 he served as lieutenant governor of Massachusetts, and from 1900 to 1902 as governor. In 1904, on the death of Senator George F. Hoar, he was appointed to the United States Senate, elected to fill the balance of the unexpired term, and re-elected in 1906, becoming one of its most influential members. Although ill health forced him to retire from public life in 1913, he retained an active interest in politics, and in 1919-1920 waged an unsuccessful fight for Republican approval of the League of Nations.

CRANE, the common name of the birds of the family Gruidae. Often confused with herons, to which they are not closely related, cranes are tall and graceful birds with long legs and a long neck. The plumage of some species is white with black wing quills, but others are brown and white, or gray; and the skin of the face, which is often devoid of feathers, is red. The beauty of some species, such as the crowned or Balearic crane and the demoiselle crane, is enhanced by ornamental plumes, which are displayed in curious courtship dances common to all cranes. Dante noted how the migratory European cranes (*Grus grus*), "chanting their dolorous notes, traverse the sky, stretched out in long array." The nearly extinct whooping crane (*G. americana*) of North

Whooping crane.

America was reduced, by 1954, to about 26 living individuals. This tallest of American birds has a wing spread of seven feet. A somewhat smaller species, the sandhill crane (*G. mexicanus*) lives in Cuba, Florida, and the Western states, ranging north to Alaska.

Cranes eat green shoots, seeds, snails, and insects which they find in marshes and open plains. They lay two eggs in a nest on a hummock in a marsh; the downy young are led away from the nest by their parents.

Consult Walkinshaw, Lawrence H., *The Sandhill Cranes* (Bloomfield Hills, Mich., 1950); Allen, Robert P., *The Whooping Crane* (New York 1952).

DEAN AMADON,
Associate Curator, Department of Birds, The
American Museum of Natural History.

CRANE, a hoisting machine so constructed as to move loads both vertically and in other directions. The use of cranes, in primitive form, can be traced back to antiquity. In modern times they have become universal, indispensable tools of industry and commerce. Cranes can be hand operated or driven by electric, steam, diesel, pneumatic, or hydraulic power. They can be (1) of the stationary type; (2) operated along overhead, side-wall, or ground rails limited to a plant area; or (3) mounted on a truck or caterpillar chassis or railroad car, for mobility. The variety of sizes and designs is extensive, consisting of adaptations of the crane's basic principles to a wide range of special uses.

Pillar Crane.—This type of crane consists of a column turning on a vertical axis, with an inclined boom which carries the load. Operating on ball or roller bearings, the boom is able to swing in a full circle, and the hoisting is done by means of a hand winch. The pillar crane is a light-duty type, usually designed for loads not exceeding 20 tons, with a working radius up to 20 feet.

Pillar Jib Crane.—This type has a mast supporting a horizontal boom. The latter is usually an I-beam, with its lower flange serving as the track for the trolley which carries the hoist forward and back. As a rule, the trolley is op-

erated by hand; the hoist, by electric or pneumatic power.

the top of the mast to the ends of two sills, or timbers, set on the ground. These are bolted or weighted down, and each is secured at one end to the base of the mast. Jinniwink derricks use an A-frame instead of a mast, with an inclined strut resting on a T-shaped frame for its base. A tower derrick, used in building construction, has a square, guyed tower with a pivoted, counterweighted boom. The boom is shifted to progressively higher footings on the tower as the building goes up.

Traveling Bridge Cranes.—Overhead traveling bridge cranes operate on elevated parallel tracks, as far apart as the width of the plant area to be serviced. A bridgelike structure consisting of one or two main girders traverses the runway on wheels. A trolley carrying the hoisting equipment moves back and forth along the bridge, and a drum powered by an electric motor winds and unwinds the hoisting cable. Cranes of this type are usually controlled by an operator in a cab or cage attached to the underside of the bridge. They range in capacity from 2 to 400 tons, and in bridge span from 20 to 120 feet.

A gantry crane is a modification of the traveling bridge crane, for use out of doors where it is not convenient to erect an overhead runway. The bridge is mounted at each end on steel legs, which run along tracks at ground level.

erated by hand; the hoist, by electric or pneumatic power.

Other Jib Cranes.—Foundry cranes, machine-shop side-wall cranes, and yard derricks are varieties of jib cranes which require that the top of the column be secured to a ceiling or wall, or be braced by struts, guy ropes, or cables. Bracket jib cranes have a horizontal I-beam jib hinged to a wall bracket, and braced by an inclined rod that is hinged to a higher bracket. This type can be made portable, to serve different areas inside a plant, by means of socket and loose-pin connections. A walking crane is a jib crane designed for longitudinal traverse, moving along a floor track with a second rail on the wall supporting the top of the mast. A traveling wall crane requires three tracks: upper and lower rails to take the thrust, and a third track mounted on wall brackets to support the vertical loads.

Derricks.—Guy derricks, of wood or steel, are used in quarries, and in bridge and building construction. This type consists essentially of a mast, braced by guy ropes and pivoted at its base, with a hinged boom whose inclination is controlled by means of tackle connecting the top ends of the mast and boom. A double-drum winch, mounted at the base, operates the hoisting (up-and-down) and luffing (in-and-out) actions. Stiff-leg derricks are similar to guy derricks, except that, instead of using guy ropes, they are supported by two inclined struts running from

Crawler Cranes.—These consist of a lower frame (with caterpillar treads or heavy-duty wheels), and a rotating upper frame carrying the hinged boom, cables, power plant, and operating machinery. The boom can be raised and lowered to handle loads at different radii. Locomotive cranes are identical with crawlers, except that they are mounted on a base frame with four or eight wheels for traveling on standard-gauge tracks.

CRANE FLY, any member of the dipterous family Tipulidae. Crane flies have long, slender legs which are weakly attached to the thorax and pull off easily. The larger ones are sometimes called daddy longlegs, and in some areas Jersey mosquitoes, although they do not bite. Their mouth parts are situated on a short or long snout. Crane flies are readily distinguished

from related families by the presence of a V-shaped depression on the top of the thorax. In size they range from one third of an inch to more than two inches. The larvae are elongate and have a distinct head and usually four anal appendages. The vast majority are aquatic or subaquatic and soft bodied, but some have a tough, brownish integument and are known as leatherjackets. These feed on the roots of plants and are sometimes serious pests of cultivated crops. More than 6,000 different kinds of crane flies have been described. See also DADDY LONGLEGS.

CRANE'S-BILL, wild geranium. See GERANIUM.

CRANFORD, township, New Jersey, situated in Union County, at an altitude of 75 feet, 5 miles west of Elizabeth, on the Rahway River, and on the Lehigh Valley Railroad (freight only) and the Central Railroad of New Jersey. Primarily a residential community, it is the seat of Union Junior College and has plants producing metal goods, heaters, baby products, and razor blades. The township was incorporated in 1871. Pop. (1950) 18,602.

CRANFORD. Not exactly a novel, Mrs. Elizabeth Gaskell's *Cranford* was first published as a series of 16 "sketches from life" in *Household Words*, a periodical which Charles Dickens was editing. When the series came to an end in 1853, the sketches were collected and issued as a book. Mrs. Gaskell wrote from memory upon Knutsford (renamed Cranford), a little country town in Cheshire, England, where she passed her childhood, where she later visited, and where she was married. And yet, though she drew freely from her recollections, her art required that she make many alterations in incident and character. Her Cranford is a town given over mostly to spinsters, who somehow manage to live in a genteel manner on small incomes inherited from a father or a mother dead long ago. A widow may be received into the society, but it is with some suspicion; and a retired army officer is welcome, provided he brings no wife. Rarely are there any marriages except among servants and shopkeepers. Mr. Hoggins, the doctor, manages to take Lady Glenmire, a newcomer, to the altar, but their conduct is frowned upon by the chaste ladies, one of whom, on retiring, always rolls a ball under her bed as a sure and easy means of detecting whether by chance a man lies concealed there to frighten her with "a great fierce face." The most exciting amusements are visits to the shops, little select parties at tea or at cards, and an occasional exhibition of a traveling juggler in the assembly rooms. A cow falls into a lime pit and loses all her hair, and her feminine owner dresses her in "a flannel waistcoat and flannel drawers" to keep away the winter's cold. The literary lady cultivates her mind with the works of Dr. Samuel Johnson, and contends that *Rasselas* far surpasses in humor anything in Mr. Dickens' *Pickwick*, then just appearing in monthly numbers. There are, of course, no children, but the younger members of the best society find something to do in chasing sunbeams from a new carpet in order that it may not fade. If Cranford has a central figure, it is Miss Matty Jenkyns, who should have married in youth Thomas Blundell, Esq., and been made happy

long ago. Both live into old age and die unmarried. Theirs is a romance of subdued but rare pathos.

Mrs. Gaskell wrote novels of wider sweep than *Cranford*. Her *Mary Barton*, for example, dealing with the conflict between labor and capital, between the manufacturer and the operatives in his mill, made a profound impression upon the Europe of her day. *Cranford* depicts a state of society which has very few resemblances to anything that may be seen in modern times; but it is a society upon which intrude none of man's darker passions—no greed or avarice or distrust or treachery. Over a woman's world as it once was, with its small duties, anxieties, fears, moderate pleasures, and respectable poverty, Mrs. Gaskell throws the glamour of her own delightful personality. Hers was a delicate humor, a true but not insistent pathos, and a charming style.

WILBUR L. CROSS,

Late Professor of English, Yale University.

CRANIAL INDEX. See CEPHALIC INDEX.

CRANIAL NERVES, the major paired nerves communicating with the central nervous system and passing into the skull. There are 12 pairs in man and the higher vertebrates and 10 pairs in fish and amphibia. An additional pair, the terminal (preoptic) nerve, occurs in all vertebrates but was not known when the numbering system was standardized. Beginning with the most anterior, the nerves are the first or olfactory, second or optic, third or oculomotor, fourth or trochlear, fifth or trigeminal, sixth or abducens, seventh or facial, eighth or auditory, ninth or glossopharyngeal, tenth or vagus, eleventh or accessory, and twelfth or hypoglossal.

Three pairs of cranial nerves supply the organs of special sense, nose, eye, and ear. The olfactory and optic nerves are composed of fibers originating in the sense organ and running to the brain as purely sensory nerves. At the optic chiasma, fibers of the optic nerve cross over to the opposite side of the brain. In forms with binocular vision approximately half of the fibers in each nerve cross over, and half are ipsilateral. The auditory nerve, concerned also with balance, is likewise a sensory nerve but possesses a ganglion along its course to the brain. Three pairs of cranial nerves (the third, fourth, and sixth) are distributed to the six muscles of the eye, and these nerves contain predominantly motor fibers. The fifth (trigeminal) nerve is one of the largest cranial nerves and bears a large ganglion (semilunar or Gasserian ganglion) near its origin. Beyond the ganglion the nerve divides into three main branches called the ophthalmic, maxillary, and mandibular nerves. The ophthalmic and maxillary nerves contain exclusively sensory fibers, while the mandibular nerve provides mixed sensory and motor elements for the lower jaw. Many of the sensations of pain in the facial area are referable to various branches of the fifth nerve.

The seventh or facial nerve arises from the medulla of the brain just anterior to the ear and bears a large (geniculate) ganglion. It supplies motor fibers to muscles of the face, neck, scalp, and ear, and also contains a sensory part as well as some fibers of the sympathetic nervous system. The sensory part includes the fibers from the taste buds of the anterior two thirds of the tongue. The facial nerve has branches com-

municating with fifth, eighth, ninth, and tenth cranial nerves. The eighth (auditory) nerve consists of two distinct branches: the cochlear (nerve of hearing) and the vestibular (nerve of equilibrium). The respective fibers arise in different structures in the internal ear and lead to different nuclei in the brain.

The ninth, tenth, and eleventh cranial nerves show a structural resemblance to the paired spinal nerves that is largely lacking in the cranial nerves anterior to the ear. These three nerves in the higher vertebrates have many communicating branches and are mixed motor and sensory nerves with sympathetic fibers. The ninth (glossopharyngeal) nerve is distributed primarily to the tongue and pharynx and includes taste fibers from the posterior part of the tongue. The eleventh (spinal accessory, accessory) nerve has two origins, cranial and spinal, some of the fibers of the latter arising as low as the fifth cervical nerve. The tenth (vagus, pneumogastric) nerve has the widest distribution of any of the cranial nerves. It courses through the neck, thorax, and abdomen. One branch supplies the heart with inhibitory fibers, and there are motor fibers to the esophagus, stomach, small intestine, and bile duct. This nerve is also distributed to the lung to form a pulmonary plexus. In the vertebrates with gills, each gill cleft receives fibers from the vagus, as does the swim bladder when it is present.

The twelfth (hypoglossal) nerve is a purely motor nerve primarily supplying the tongue. In lower vertebrates with 10 cranial nerves there are spino-occipital nerves which are probable homologues of the hypoglossal.

WILLIAM L. DOYLE,
*Professor of Anatomy, Department of Medicine,
University of Chicago.*

CRANIOTOMY. See OPERATIONS, SURGICAL—*Operations on the Nervous System.*

CRANIUM. See SKULL.

CRANK, in mechanics, is a fundamental form of the lever. The word, which is derived from the Anglo-Saxon *cranc*, meaning basically "to turn" or "to twist," signifies primarily a bend, the simple form of the crank consisting of the bent portion of an axle with which the axle is turned. In a windlass the crank is the crosspiece joining the axle and the handle. In a steam engine the crank may take the form shown in the accompanying diagram at 1, in which the broad end of the crank is keyed fast to a rotating shaft, and the smaller end is loosely bolted with a crank-pin to a connecting rod, to produce reciprocating motion.

Sometimes the crank takes the form of a wheel, as at 2, and is then termed a wheel crank. In the diagram the other end of the connecting rod is connected with a piston.

The double crank shown at 3 is employed

where the crank interrupts the axle lengthwise. In the diagram, *B* and *B* are the cranks, and *A* is the connecting rod. A three-throw crank consists of three of these double cranks on one axle. When there are two or more cranks on one axle, they are placed on opposite sides so as to balance. The one theoretical difficulty in the use of a single crank is that it has two dead centers in each revolution, the dead center being the point at which, if the motion is stopped, the parts are so aligned that neither a push nor a pull on the connecting rod will start rotation. With a three-throw crank the dead centers are timed so that one crank is always in working position.

A bell crank is a bent lever somewhat resembling an engine crank. It is used to change the direction of motion of a wire that pulls a mechanically operated bell.

The crank is the simplest device known for changing reciprocating (back-and-forth) motion into rotary motion, or vice versa, since it has few parts and nothing to get out of order, and the reciprocating part slows up and starts again with the most desirable speed ratio, obviating all shocks in the machine.

CRANMER, Thomas, English prelate and reformer: b. Aslacton, Nottinghamshire, England, July 2, 1489; d. Oxford, March 21, 1556. He was educated at Cambridge University, from which he received his B.A. degree in 1512 and his M.A. in 1515, and became a fellow of Jesus College. Ordained in 1523, he was appointed reader of a theological lecture at Jesus and public examiner of candidates for degrees in theology. In 1529, while he was staying at Waltham Abbey, he made the observation on the mediated divorce of King Henry VIII from Catherine of Aragon that the question of its propriety might better be decided by consulting learned divines and members of the universities than by an appeal to the pope. Cranmer suggested that if the queen's prior marriage to Prince Arthur were established, this would nullify her marriage to the king. His opinion gained the favor of Henry, who summoned Cranmer and ordered him to write a treatise on the subject. He was also made a king's chaplain. In 1530 he accompanied a mission to a meeting of the pope and Emperor Charles V at Bologna, and then went to Rome, where he had an interview with the pope. Two years later he was sent on a diplomatic mission to the emperor. While in Germany, he collected the opinions of various divines and canonists on the validity of Henry's marriage, and became acquainted with a number of reformers, including Andreas Osiander, whose niece he married.

Returning to England on his appointment as archbishop of Canterbury, he was consecrated at Westminster on March 30, 1533. Soon thereafter he declared the marriage of Henry and Catherine null and void, and confirmed the king's marriage with Anne Boleyn. He crowned Anne queen and served as godfather to the future Queen Elizabeth I. Archbishop Cranmer supported Henry's claim to supremacy over the Church of England, which was confirmed by Parliament in 1535 in the Act of Supremacy. In 1536 he annulled the king's marriage with Anne, and in 1537 he stood as godfather to the future King Edward VI. He attempted unsuccessfully to prevent passage of the Six Articles, abolishing diversity of opinion in theological matters. The revised English translation of the Bible, ordered in 1539 to be placed in

churches, received the name of *Cranmer's Bible*.

On the death of Henry, in 1547, the archbishop was named one of the executors of his will and a member of the regency appointed to govern the kingdom during the minority of Edward VI. He proceeded to model the Church of England according to the notions of Huldreich Zwingli, rather than those of Martin Luther. Under his direction the liturgy was drawn up and established by act of Parliament, and the prayer book and articles of religion (42 at first, later reduced to the famous Thirty-nine Articles) were compiled, the validity of which was enforced by royal authority and for which infallibility was claimed. The exclusion of Princess Mary from the crown by the will of Edward VI (d. 1553) was endorsed by Cranmer along with the partisans of Lady Jane Grey, apparently in opposition to his own judgment. With others who had been most active in her elevation, he was sent to the Tower on the accession of Mary. He was tried for treason, and being condemned, was sentenced to death but was spared by the queen, although he lost his position as archbishop of Canterbury. In March 1554 he was sent to Oxford with Nicholas Ridley and Hugh Latimer, and after being kept in prison for nearly a year and a half was formally tried. Cranmer's trial took place before a papal commissioner on the charges of blasphemy, perjury, incontinence, and heresy, and he was sentenced to be deprived of office and executed. After this, promises were made which induced him to sign a recantation of his alleged errors. He was placed on a scaffold in St. Mary's Church the day he was to suffer, there to listen to a declaration of his faults and heresies. Instead of confessing the justness of his sentence and submitting to it in silence or imploring mercy, he calmly acknowledged that the fear of death had made him belie his conscience, and declared that nothing could afford him consolation but the prospect of extenuating his guilt by encountering, as a Protestant penitent, with firmness and resignation, the fiery torments which awaited him. According to an eye witness report, after finishing his confession, he literally ran up the steps leading to the stake, with his guardians running after him. He was tied to the stake, the fire was lit and Cranmer, as he had promised, kept his right hand, with which he had signed his recantation, extended in the flames, that it might be consumed before the rest of his body, exclaiming from time to time, "This hand hath offended."

CRANNOG, krăn'ög, a fortified lake dwelling. See LAKE DWELLINGS.

CRANSTON, krăn'stün, **Earl**, American Methodist bishop: b. Athens, Ohio, June 27, 1840; d. near New Richmond, Ohio, Aug. 18, 1932. He was graduated at Ohio University 1861 and served in the cavalry during the Civil War, rising to the rank of captain. He entered the Methodist Episcopal ministry (1867) and after serving numerous parishes, was publishing agent of the church from 1884 to 1896 when he was elected a bishop. During 1898-1900 he visited China, Japan, and Korea in discharge of his episcopal duties. He was commissioned by his church to unite all Methodist missions in Japan into one Japanese Methodist Church in 1907. He became resident bishop at Washington, D.C., in 1904 and retired in 1916 and devoted himself to the task of uniting the Methodist Church in America which had separated over the question of slavery.

CRANSTON, city, Rhode Island, in Providence County, altitude 60 feet, on the Pawtuxet River, served by the New York, New Haven and Hartford Railroad, four miles southwest of Providence. Surrounded by agricultural and industrial areas, its own industries are the manufacture of machinery, metal goods, plastics, rubber goods, chemicals, fire extinguishers, and textiles, especially print goods. It has several public libraries and is the seat of some state institutions, including a reformatory for boys and one for girls, a hospital, and a state prison. The villages of Arlington, Auburn, Meshanticut Park, and Pawtuxet are part of Cranston. Settled about 1638, incorporated as a township in 1754 and at that time named in honor of the colonial governor, Samuel Cranston, it became a city in 1910. It has a mayor and council type of government. Pop. (1950) 55,060.

CRANTARA, krăn-tä'rà (Gael. *crann*, wood or beam; *tair*, gathering) a half burned cross, dipped in blood, which was the rallying symbol in the Highlands of Scotland on any sudden emergency. It was dipped in blood to imply that any clansman failing to answer the call would suffer in kind. The Highlanders appear to have borrowed it from the ancient Scandinavians, of whose use of it Olaus Magnus, in his *Historia de Gentibus Septentrionalibus* (1555), gives a particular account. It was also called *crois-taraidh* or *croishtarich*.

CRANTOR, krăn'tör, Greek philosopher: b. Soli, Cilicia, c.335 B.C.; d. about 275 B.C. A pupil of Xenocrates at the Academy in Athens, he is best known for his commentary on Plato's *Timaeus*, the first commentary on Plato, and for his religious and philosophic work on grief.

CRAPPIE, kräp'i, a common name applied to two members of the freshwater sunfish group, the white crappie, *Pomoxis annularis*, and the black crappie, *Pomoxis nigromaculatus*. The white has six dorsal spines; the black, seven or eight. The length of the dorsal fin is relatively short in the white and long in the black. The greenish vertical bands of the white crappie are more conspicuous than those of the black.

Crappies range naturally from southern Canada through the Great Lakes area south to Florida and the Gulf of Mexico, and west to

CRASH — CRATAEGUS

Crappie

Nebraska, the white being more abundant in the southern parts of the range, and the black in the northern. Both species have been widely introduced into other waters.

CRASH, a coarse, heavy fabric, generally of linen, but sometimes of jute, cotton, or a mixture of fibers. It is used for toweling, table linen, suiting material, and draperies.

CRASHAW, krăsh'ô, Richard, English poet of the metaphysical school: b. London, England, ?1613; d. Loreto, Italy, Aug. 21, 1649. The son of William Crashaw (1572-1626), a Puritan poet and clergyman, he was educated at Charterhouse and at Pembroke Hall, Cambridge University, receiving his B.A. degree in 1634 and his M.A. in 1638. In 1634 he published anonymously a volume of 185 Latin epigrams, entitled *Epigrammatum Sacrorum Liber*. He became a fellow of Peterhouse in 1637, but lost his fellowship in 1643 because of his refusal to accept the Solemn League and Covenant. Three years later he went to Paris, where he became a convert to the Roman Catholic faith. Through the influence of his friend Abraham Cowley, he was introduced to Queen Henrietta Maria, who recommended him to Cardinal Palotta and others at Rome. In 1649 the cardinal made him a subcanon at Loreto. Crashaw's principal published work appeared in London in two parts in 1646. The first, entitled *Steps to the Temple*, is a collection of religious poems showing the influence of George Herbert. The second, called *The Delights of the Muses*, consists of secular poems. A second edition appeared in 1648; a third, bearing the title *Carmen Deo Nostro Te Decet Hymnus*, and including 12 engravings made from the poet's designs, was published in Paris in 1652. Crashaw also left many poems in manuscript.

CRASSULACEAE, krăs-û-lă'sê-ê, the orpine family, belonging to the order Rosales. Various circumscribed, the family includes several to more than 30 genera and from 500 to over 1,000 species of annual or perennial succulent herbs and shrubs and a few climbing members. It is widely distributed in dry regions, especially south central Asia, the Mediterranean area, South Africa, and Mexico, but few species are found in South America and practically none in Australia and Oceania. Well-known genera are stonecrop (*Sedum*), with about 350 species mostly of the temperate and northern boreal regions; houseleek (*Sempervivum*), with some 30 species of Eurasian distribution; the South African genus *Crassula*, with some 250 species; the African and Asian genus *Kalanchoe*, with 125 species; and the Mexican genus *Echeveria*, with some 80 species. Fanciers of succulent plants grow some 400 species belonging to about 20 genera as ornamentals.

THEODOR JUST.

CRASSUS, Lucius Licinius, Roman orator and politician: b. 140 B.C.; d. 91 B.C. In his early years a supporter of the Gracchi, he later became

more conservative in his views. In 95 B.C., he was elected consul together with Quintus Mucius Scaevola. During his term of office he proposed a law compelling all persons who were not citizens to leave Rome, a measure which proved a major cause of the Social War (q.v.). As censor in 92 B.C., he closed the schools of the rhetors on the ground that their influence on the minds of the young was bad. Crassus was a patron of the arts, and his mansion on the Palatine Hill was noted for its architecture, statuary, and paintings. The leading orator of his time, he was introduced as a speaker in *De Oratore*, as the representative of Cicero's own views on the subject of oratory.

CRASSUS, Marcus Licinius (surnamed Dives, meaning "the Rich"), Roman financier and politician: b. about 115 B.C.; d. Carrhae, Mesopotamia, June 6, 53 B.C. The younger son of Publius Licinius Crassus, who served as consul in 97 B.C. and committed suicide in 87 after being proscribed by the supporters of Gaius Marius, he fled to Spain after his father's death. When Lucius Cornelius Sulla returned to Italy in 83, Crassus joined him and rendered him important services, including a major contribution to Sulla's victory at the Colline Gate in 82. He was rewarded with donations of confiscated property and was permitted to purchase other confiscated estates at an almost nominal value. By these means and by subsequent real estate speculations he acquired a substantial fortune. As praetor in 71, he was in command against Spartacus and the revolted slaves. Spartacus and a large number of his followers were defeated and killed. In the following year, Crassus was elected consul with Pompey the Great, and in 65 he became censor. With Gaius Julius Caesar and Pompey, he formed in 60 the First Triumvirate, to which he gave substantial financial assistance. In 55 he again shared the consulship with Pompey, and the next year secured the proconsulship of Syria. Ambitious for military success, he undertook a campaign against the Parthians in 54, but after invading western Mesopotamia returned to Syria. In the following year he set out again, crossed the Euphrates River, and met the enemy near Carrhae (modern Haran). Badly defeated, he retreated to the town, where he was treacherously slain at a conference with the Parthian general.

His younger son, PUBLIUS LICINIUS CRASSUS (c.85-53 B.C.), served in Gaul under Caesar. He helped to defeat Ariovistus (58), conquered the coastal tribes (57), and defeated the Aquitanians (56). After returning to Rome in 55, he accompanied his father in the campaign against the Parthians, in which he lost his life.

CRATAEGUS, kră-tê'gûs, or **HAW-THORN** (also called **HAW** and **THORN**), a large genus of shrubs or small trees, 20 feet or more in height, found mostly in the temperate parts of Eurasia and the Americas south to the Andes, belonging to the rose family (Rosaceae). It is most abundant in the north-eastern and central United States, where more than 1,000 species have been described. For the Eastern states, however, it is more practical and scientifically sound to recognize about 100 species and some 60 local forms that may prove to be hybrids.

The leaves of *Crataegus* are alternate, simple,

and highly variable in shape and in type of margin (most are irregularly toothed), depending on whether they are vegetative leaves found on sterile shoots or ends of branches or floral leaves found on flowering branchlets or spurs. The perfect flowers, which resemble apple blossoms, appear in late spring or early summer. They are white or whitish, are grouped in showy clusters at the ends of twigs, and measure one-half to one inch across. Often they have a disagreeable odor. The fruit is a small reddish pome (like an apple) of varying flavor; it has a rather large, hard, separable center. The common names of the genus refer to the frequent presence of formidable thorns on the twigs, whereas the classical name is derived from the Greek word *kratos*, meaning strength, alluding to the hard, close-grained, reddish brown wood.

Hawthorn (*C. monogyna*) was introduced in early American gardens, whence it escaped and became established. *C. Oxyacantha*, with sharp thorns, is a frequently cultivated tree over 20 feet tall. A well-known indigenous species is the cockspur thorn (*C. crus-galli*), a tree growing to 20 feet or more and, with its many forms, very common in the Central and Eastern states.

Thorns are ubiquitous pasture weeds, often growing along fence rows or overrunning grazing lots, where cattle browse for young growths. The fruits are eaten by many birds, deer, gray foxes, and other animals. In addition to these uses, thorns are a source of honey, their wood may be used for turning, and they are planted for soil anchorage in eroded areas.

Any study of this genus is exceedingly difficult and requires careful collecting of the various types of leaves, flowers, and fruits, all of which should be taken from the same tree, preferably for a period of two successive years. The number of stamens and the color of the anthers and ripe fruit should also be recorded in the field.

THEODOR JUST,

Chicago Natural History Museum.

CRATCHIT, Bob, a character in *A Christmas Carol* by Charles Dickens. He is the father of Tiny Tim and the clerk of Ebenezer Scrooge.

CRATER, in astronomy, a southern constellation near the autumnal equinox. One of the constellations described by Ptolemy, it is located between Leo and Corvus. It contains 35 stars visible to the naked eye, the two largest being of the fourth magnitude.

CRATER, in geology, the opening on the tops or sides of volcanic mountains through which the lava and ashes are ejected. The crater of Mount Etna, like those of many of the most ancient volcanoes, does not retain the bowl-like shape to which the name owes its origin; that of Vesuvius, however, preserves the typical form. Variations in the form of the crater are due to the varying violence of the eruption. The more powerful eruptions tear off the top of the mountain and produce the hollowed cup. The craters of the Hawaiian volcanoes are usually large, Kilanea on Mauna Loa being about two miles in diameter and filled with a lake of molten rock. Such large craters are known as *calderas*. See also **VOLCANO**.

CRATER LAKE, in general a term applied to any lake occupying the crater of an extinct or

dormant volcano. In the United States the name is applied to a vividly blue lake in Crater Lake National Park (q.v.).

CRATER LAKE NATIONAL PARK, a 250.4-square-mile area located in Klamath County, southern Oregon, on the crest of the Cascade Range. It has as its central feature vividly blue Crater Lake, the deepest lake in North America and the fifth deepest lake in the world. This beautiful body of water lies in the heart of Mount Mazama, an ancient volcano whose destruction many years ago resulted in the formation of a vast crater in which water, derived from rainfall and snowfall, accumulated. The lake is 1,983 feet deep, 5 miles wide, and 6 miles long, and has a 20-mile shoreline from which rise multicolored lava cliffs 500 to 2,000 feet high.

Crater Lake has no inlet, and no outlet except by seepage. Evaporation, seepage, and precipitation are in a state of balance, and as a result the water level remains almost constant. The brilliant blue of the water is said to be caused chiefly by the scattering of sunlight in its clear depths, the blue rays of the sunlight being reflected from the water and the rays of other colors being absorbed. Rising above the surface of the lake are Wizard Island, a symmetrical cinder cone 780 feet high, and the Phantom Ship, 169 feet high, its shape suggesting a ship under full sail.

Excellent views of the lake may be had from observation points on the 35-mile drive which circles the rim of the crater. Trails lead from the drive to such high points on the rim as Mount Hillman, Garfield Peak, and the Watchman, as well as to Mount Scott (8,938 feet), highest point in the park, located back from the rim. The lake shore is accessible by trail. Launches and rowboats are available for scenic trips around the lake and for trout fishing.

Crater Lake National Park has numerous trees, most of them cone bearers, and more than 570 species of flowering plants and ferns. Numerous small animals, such as golden-mantled ground squirrels, chipmunks, marmots, conies, and badgers, inhabit the park, and there are also some large species, such as bear and deer. More than 120 bird species have been noted, among them the golden eagle, southern bald eagle, falcon, and osprey.

Crater Lake was discovered on June 12, 1853, by John Wesley Hillman, a young prospector leading a party in search of the so-called Lost Cabin Mine. They named their discovery Deep Blue Lake. About a decade later, Chauncey Nye, leading a party of prospectors from eastern Oregon through the region, happened upon the lake. Thinking they had made a discovery, the prospectors named it Blue Lake. Yet another "discovery" was made in 1865 by two soldiers stationed at Fort Klamath, who called it Lake Mystery. In 1869 the lake was renamed Crater Lake by a group of visitors from Jacksonville, Oreg.

Crater Lake was little known until William Gladstone Steel visited it in 1885. Inspired by its beauty, Judge Steel conceived the idea of preserving it as a national park, an idea which he worked for assiduously until 1902, when Congress established the park, which now is administered by the National Park Service of the Department of the Interior. Following the establishment of the park, Judge Steel devoted his life to its development. He served as the second

superintendent of the park and later as park commissioner, an office he held at the time of his death in 1934.

CRATER MOUND or METEOR CRATER (formerly known as COON BUTTE), depression, Arizona, situated in Coconino County. This feature in the plains 20 miles west of Winslow is one of the most remarkable natural wonders in existence. It consists of a crater 600 feet deep and 4,000 feet in diameter surrounded by a rim 100 to 150 feet high. This rim consists of loose fragments of rock and sand from the hole. The walls of the hole are limestone (Kaibab) and sandstone (Coconino), more or less upbent and shattered. The relations are shown in the accompanying figure. The cause of this extraordinary hole is one of the perplexing questions over which scientists speculate. It has been suggested that the crater was caused by impact of a large meteor, a view sustained by the occurrence of

Section through Crater Mound, Arizona Plateau.

many small masses of meteoric iron in the vicinity, but a mining company organized to find and work the large mass of iron presumably buried in the hole obtained no evidence of its existence. A detailed survey with a magnetic needle hung to swing vertically also failed to indicate the presence of a body of metallic iron. A plausible suggestion is that the hole was caused by the explosion of volcanic steam accumulating in the porous sandstone under the dense limestone and finally reaching the limit of tension. Many conspicuous volcanic features occur in the general neighborhood but not in the immediate vicinity of the hole. Closely similar craters due to explosion are known in the Southwest, in Mexico, and in other parts of the world.

N. H. DARTON,

Late Director, United States Geological Survey.

CRATERS OF THE MOON NATIONAL MONUMENT, a 73.8-square-mile area located in Butte and Blaine counties, south central Idaho, established on May 2, 1924, to preserve a spectacular display of lava flows, cinder cones, and other volcanic phenomena. In its general appearance the area is suggestive of the surface of the moon as viewed through a telescope.

CRATERUS, krăt'ēr-ūs, Macedonian general: b. about 370 B.C.; d. Cappadocia, 321 B.C. One of Alexander the Great's most distinguished marshals, he fought in all the major battles in the East, from the Granicus (334 B.C.) to India (326). After the assassination of Parmenio in 330, he served virtually as second in command. Following the death of Alexander (323), Craterus was associated with his father-in-law, Antipater, as ruler of Macedonia and Greece. He was defeated and killed by Eumenes of Cardia.

CRATES, krăt'ēz, Greek comic poet: fl. about 450 B.C. His eminent success as an actor was repeated in his plays, which won praise from

Aristophanes and Aristotle. Crates was the first to concoct plots of a general character and to introduce intoxicated characters onto the comic stage. To him are ascribed 14 comedies, to 10 of which are assigned the 52 extant fragments of his work.

Consult Kock, Theodor, *Comicorum Atticorum Fragmenta*, vol. 1, pp. 130-44 (Leipzig 1880).

CRATES OF MALLUS, Greek grammarian: fl. about 160 B.C. He founded at Pergamum the grammatical school which, deriving its linguistic principles from Stoicism, espoused the system of anomaly in rivalry with the Alexandrian school of grammar under Aristarchus, who taught the system of analogy. (These systems treated mainly conjugational and declensional matters.) Crates probably supervised the composition of the Pergamene Library's catalogue. He introduced the formal study of literature into Rome, while on an embassy there about 159 B.C. His school had many eminent scholars and a long-lasting influence on Hellenistic theories of grammar.

While Crates commented critically and with antiquarian and allegorical interest on Greek poets such as Hesiod, Euripides, and Aristophanes, his chief commentary, which won much acclaim, was on the Homeric epics. Only a few fragments survive from these works and other treatises (agricultural, geographical, and scientific) ascribed to Crates of Pergamum, who may have been the grammarian.

Consult Sandys, J. E., *A History of Classical Scholarship*, 2d ed., vol. 1, pp. 156-60, 172 ff. (Cambridge, England, 1906).

CRATES OF THEBES, Greek Cynic philosopher: b. Thebes, about 365 B.C.; d. 285 B.C. Renouncing a large patrimony, which he bestowed on his native city, he migrated to Athens, where he imitated the self-control of his teacher, Diogenes, the notorious Cynic, but was more gracious in its practice than his master and became one of the most prominent professors of Cynicism. He taught Zeno, who founded Stoicism, and thus formed the link between the Cynics and the Stoics. Crates wrote many letters on philosophical problems and composed tragedies, all of which have been lost. Curious details of his career are given in Diogenes Laërtius' *Lives and Opinions of Eminent Philosophers* (book 6, chap. 5).

CRATINUS, krăt-i'nūs, Greek comic poet: b. about 484 B.C.; d. about 419 B.C. Although he began his dramatic career late in life, he lived to achieve much in his profession, exhibiting 21 comedies, of which 9 gained first prize (1 over Aristophanes) in the dramatic contests at Athens. Ancient authorities ranked him with Aristophanes and Eupolis as one of the greatest masters of Old Comedy. Cratinus found Greek comedy employed merely to excite merriment, but, while conserving its mirthful character, he converted it into a terrible weapon for chastisement of public and private vice and for satirical comment on prominent politicians. Thus he set the role peculiar to the poets of Old Comedy: severe censorship over contemporary politics and morals. Cratinus also developed that genre of comedy which burlesqued mythological characters. Whether he fixed the number of actors, which hitherto had been fluid, at three is uncertain, though he made some changes in comedy's external form. Vigor-

ous and direct in style, caustic in wit and satire, and ingenious in the invention of plots, he boldly changed the meaning of old words and cleverly coined new ones. His choruses were so admired that they were often sung at banquets. His dramas survive in 455 fragments, of which 182 are either too brief or too blind to allow assignment to his known plays.

Consult Kock, Theodor, *Comicorum Atticorum Fragmenta*, vol. 1, pp. 11-130 (Leipzig 1880).

CRATINUS, Greek comic poet: fl. about 350 B.C. An Athenian playwright of Middle Comedy, he sometimes is confused with his older and more celebrated namesake (c.484-c.419 B.C.). Consequently some scholars suppose that several of the comedies ascribed by ancient authorities to the elder Cratinus should be assigned to the younger. The 13 extant fragments apportioned among the nine plays attributed to him are too scanty to allow a confident appreciation of his style.

Consult Kock, Theodor, *Comicorum Atticorum Fragmenta*, vol. 2, pp. 289-93 (Leipzig 1884).

CRATIPPUS, krā-tīp'ūs, Greek historian: fl. about 390 B.C. Ancient authors report that he continued Thucydides' unfinished *History of the Peloponnesian War* by describing events in Hellas during 411-404 B.C., and then added a history of Hellas to 394 B.C. Only a few fragments of his work survive. There have been modern attempts to ascribe to him the authorship—which still awaits solution—of the *Hellenica Oxyrhynchia*, two groups of papyrological fragments (found in 1906 and 1934) giving a detailed history of Hellas for 396-395 B.C.

Consult Jacoby, Felix, "The Authorship of the *Hellenica* of Oxyrhynchus," *Classical Quarterly*, 44:1-11 (1950).

CRATIPPUS OF MYTILENE, Greek Peripatetic philosopher: b. Mytilene, ?75 B.C. He was held in the highest admiration by some of the principal Romans of his generation. Cicero, who called him the prince of all the philosophers whom he had heard and the peer of the most eminent Peripatetics, audited his lectures (51 B.C.) and sent his son to study under Cratippus in 44 B.C., when the latter was president of the Lyceum at Athens. After his defeat at Pharsalus (48 B.C.), Pompey received from Cratippus philosophical consolations on the lost cause of republicanism. Caesar conferred on the philosopher the prized possession of Roman citizenship (c.46 B.C.). Brutus attended his classes, while he prepared at Athens (44-43 B.C.) to resist Octavian and Antony. The only known treatise (now lost) of Cratippus treated divination, of which he eschewed all kinds except those induced by dreams and by frenzy.

CRAU, krō, plain, France, situated in Bouches-du-Rhône Department, west of the delta of the Rhone River and south of the Alpines. Covering an area of approximately 80 square miles, it consists partly of marshy lowlands and partly of stony wasteland. By means of irrigation canals from the Durance River grapes and olives are raised in some sections of the Crau, and sheep are raised elsewhere.

CRAUE, krōk, Gustave Adolph Désiré, French sculptor: b. Valenciennes, France, July

16, 1827; d. Paris, Nov. 17, 1905. A student of James Pradier, he won the Prix de Rome in 1851. Among his notable works are monuments to Admiral Gaspard de Coligny (Rue de Rivoli, Paris) and Charles Martial Cardinal Allemand-Lavignerie (Carthage); *La victoire couronnant le drapeau français* (Place des Arts et Métiers, Paris); *Le Crépuscule* (Avenue de l'Observatoire, Paris); a statue of Gen. Antoine Eugène Alfred Chanzy (Le Mans); and busts of Marshals Adolphe Niel and Patrice de MacMahon and of Empress Eugénie. There is a museum dedicated to Crauk in Valenciennes.

CRAVEN, Avery Odelle, American historian: b. Randolph County, N. C., Aug. 12, 1886. He was educated at Simpson College (B.A., 1908), Harvard University (M.A., 1914), and the University of Chicago (Ph.D., 1923). After teaching at the College of Emporia (1920-1922), Michigan State College (1923-1924), and the University of Illinois (1924-1928), he became associate professor and then (1929) professor of American history at the University of Chicago. His published works, dealing mainly with phases of Southern history and with the Civil War (which he maintains could have been avoided), include *Soil Exhaustion as a Factor in the Agricultural History of Virginia and Maryland, 1606-1860* (1926); *Edmund Ruffin, Southerner: A Study in Secession* (1932); *The Repressible Conflict, 1830-1861* (1939); *Democracy in American Life: A Historical View* (1941); *The Coming of the Civil War* (1942); *The United States, Experiment in Democracy* (with Walter Johnson, 1947); and *The Growth of Southern Nationalism, 1848-1861* (1953).

CRAVEN, Pauline, French author: b. London, England, April 12, 1808; d. Paris, France, April 1, 1891. The daughter of a diplomat, Comte Auguste Marie de la Ferronays, who served briefly as foreign minister during the reign of Charles X, she married in 1834 a British diplomat, Augustus Craven (d. 1884), grandson of the margravine of Anspach. She traveled extensively and spent much time in England and Italy. Her most celebrated work, *Récit d'une soeur, souvenirs de famille* (1866), which was crowned by the French Academy, tells the story of the vicissitudes of her own noble Roman Catholic family. Her first novel, *Ann Séverine* (1868), was followed by *Fleurange* (1869); *Le mot de l'énigme* (1874); and *Le Valbriant* (1886). Among her other published works are *La marquise de Mun* (1877); *Réminiscences: Souvenirs d'Italie et d'Angleterre* (1879); *La jeunesse de Fanny Kemble* (1880); and *Lady Georgiana Fullerton, sa vie et ses oeuvres* (1888).

CRAVEN, Thomas Tingey, American naval officer: b. Washington, D.C., Dec. 20, 1808; d. Boston, Mass., Aug. 23, 1887. The brother of Tunis Augustus Macdonough Craven (q.v.), he joined the United States Navy as a midshipman in 1822, and became a lieutenant in 1830. In 1838-1839 he served as first lieutenant of the *Vincennes*, the flagship of Lieut. Charles Wilkes' exploring expedition in Antarctic waters. He aided Commodore Matthew C. Perry in suppressing the slave trade off the African coast in 1843-1844, and in 1852 was promoted to the rank of commander. From 1850 to 1855 and again from 1858 to 1860 he was commandant of midshipmen

at the United States Naval Academy. He became a captain in 1861, and in the following year, while in command of the *Brooklyn* of Admiral David G. Farragut's squadron, assisted in the capture of New Orleans. While in command of the *Niagara* in 1863, he was promoted to the rank of commodore and ordered to European waters. He captured the *Georgia*, a Confederate steamship, off Portugal in 1864, but in the following year, outmatched by the Confederate ironclad *Stonewall*, refused its challenge. This action resulted in a court martial sentence of two years' suspension, which was set aside by Secretary of the Navy Gideon Welles. Promoted to the rank of rear admiral in 1866, he retired from the navy three years later.

His son ALFRED CRAVEN (b. Bound Brook, N. J., Sept. 16, 1846; d. Pleasantville, N. J., Sept. 30, 1926) was a civil engineer. A graduate of the United States Naval Academy (1867), he was a surveyor and mining engineer in California and Nevada from 1871 to 1884, when he moved to New York City. He was an engineer on the Croton Aqueduct (1884-1895); in charge of construction of the Jerome Park Reservoir (1895-1900); in charge of construction of the Broadway subway from 42d Street to 104th Street (1900-1905); deputy chief engineer of the Rapid Transit Commission (1905-1907); deputy engineer of subway construction for the Public Service Commission (1907-1910); and acting chief engineer and later chief engineer in charge of construction of the dual system of subways (1910-1916). After retiring in 1916 he served as a consultant to the Public Service Commission and its successor, the Transit Construction Commission, until 1920.

CRAVEN, Tunis Augustus Macdonough, American naval officer: b. Portsmouth, N. H., Jan. 11, 1813; d. Mobile Bay, Ala., Aug. 5, 1864. The youngest brother of Thomas Tingey Craven (q.v.), he joined the United States Navy as a midshipman in 1829 and became a passed midshipman in 1835. In that year he was first assigned to coastal surveying, a field in which he specialized during most of his naval service. He became a lieutenant in 1841 and a commander in 1861. He was chief editor of the *United States Nautical Magazine* (1845-1846); served in the Pacific Squadron (1846-1849); and was in charge of surveying a canal route through the Isthmus of Panama (1857-1858). While in command of the *Mohawk* (1859-1861), he captured a slave ship off the coast of Cuba. After the outbreak of the Civil War he was instrumental in preventing the Confederate capture of Key West. He served in European waters from 1861 to 1863, when he was given command of the ironclad *Tecumseh*. After serving in the James River, he was ordered to join Admiral David G. Farragut off Mobile, where he arrived on Aug. 4, 1864. In the ensuing Battle of Mobile Bay, the *Tecumseh* fired the first shot. Less than an hour later the ship struck a mine and sank, and Craven and almost all the members of the crew lost their lives.

CRAVEN, William, EARL OF CRAVEN, English Royalist: b. 1606; d. April 9, 1697. The eldest son of Sir William Craven (1548?-1618), who was lord mayor of London in 1610-1611, he attended Trinity College, Oxford, and entered the service of Maurice of Nassau, prince of

Orange, and his successor, Frederick Henry. Returning to England in 1627, he was knighted and created Baron Craven of Hampsted Marshall. In 1631 he became a commander of English troops under Gustavus Adolphus in Germany. In the following year he made a fruitless attempt to recover the Palatinate for Elector Frederick V and his consort, Elizabeth of Bohemia, daughter of James I of England. A similar effort on behalf of their son, Charles Louis, in 1637 was also unsuccessful, and Craven was taken prisoner. Ransomed two years later, he returned to England and gave considerable financial assistance to Charles I during the civil war. Subsequently he became a member of Elizabeth of Bohemia's court in the Netherlands and extended aid to her and to the exiled Charles II. His estates in England were confiscated by Parliament in 1651, but he recovered his fortune after the Restoration, when his loyalty was rewarded with numerous honors. In 1664 he was created Viscount Craven of Uffington and earl of Craven. He served as privy councilor (1666 and 1681), lieutenant general (from 1667), and lord lieutenant of Middlesex and Southwark (1670-1689). At James II's accession in 1685 he again became a member of the Privy Council and was made lieutenant general of the forces.

CRAWFISH. See CRAYFISH.

CRAWFORD, Francis Marion, American novelist: b. Bagni di Lucca, Italy, Aug. 2, 1854; d. Sorrento, Italy, April 9, 1909. Brought up mainly in Italy, where his American father, Thomas Crawford (q.v.), had long resided as a sculptor of some note, young Crawford received an amazingly varied and cosmopolitan education. He was early fluent in several languages—English, Italian, and French (the language of his governess), and soon was to know most European languages, including Russian and Turkish, and many Oriental tongues. At 12 he went to the United States and spent two years at St. Paul's School, Concord, N. H., then entered Harvard for a short period. He spent four years (1870-1874) in England, mainly at Trinity College, Cambridge, where he studied Spanish, German, and Swedish, followed by two years at Karlsruhe and Heidelberg, Germany, and a similar period at the University of Rome, where he specialized in Sanskrit.

His father had died, and the consequences of the panic of 1873 had greatly depleted his mother's fortune. In 1879, Francis went to India and, turning to journalism for a living, edited the *Indian Herald* at Allahabad for a year and a half, meanwhile continuing his studies of Eastern languages and philosophy. In 1881 he again went to the United States, living in New York and Boston; while writing for various periodicals, he studied Sanskrit and Zend at Harvard. In Boston he made his home with his maternal aunt, Julia Ward Howe, author of *The Battle Hymn of the Republic*.

The turning point in the young man's career came when he told his uncle, Samuel Ward, a story about the adventures of a diamond merchant in India. Urged to set it down on paper, Crawford, then 28, wrote his first novel, *Mr. Isaacs*, in less than six weeks. The book (1882) was a sensation; he had found a well of fiction in himself. With his abounding energy and his background of travel in romantic places, he poured

forth a stream of historical romances, sometimes finishing one in a single month, often publishing 2 or 3 in a single year. His books were immensely popular. In 25 years he produced more than 40 novels, besides serious historical and critical works of philosophy, philology, and archaeology. His only play, *Francesca da Rimini*, was produced by Sarah Bernhardt in Paris in 1902.

Naturally much of the high-speed output of F. Marion Crawford, as he signed himself, was ephemeral and of little artistic merit. But his Italian series, depicting the life of a noble Roman family in the picturesque setting he knew and loved so well, has held the respect of literary critics. These novels beginning with *Saracinesca* (1887) and including *Sant' Ilario* (1889), *Don Orsino* (q.v., 1892), and *Corleone* (1896) have been lauded as works of high dramatic and aesthetic quality, "hardly equalled in their kind by the romances of any other American writer." *A Cigarette Maker's Romance* (1890) has also won praise as displaying his technique at its soundest and most characteristic. Among his novels with an American locale, generally depicting aspects of New York life, *The Three Fates* (1892) is rated highest. His scholarly side as historian and archaeologist is found in the group of which *Ave Roma Immortalis* (1898) is most conspicuous. His two novels written in both English and French—*Zoroaster* (1885) and *Marsio's Crucifix* (1887)—won him a French Academy prize.

Crawford viewed the novel as "a pocket theater," and his own writing was frankly designed for entertainment (see his *The Novel—What It Is*, 1893). He had the authentic gift of the born storyteller, he was a master of plot and of dialogue, and he excelled in creating vivid characterizations and scenic pictures. Though he settled at Sorrento in 1885 in a villa overlooking the Mediterranean, Crawford was a great traveler; he made numerous trips to the United States and, as captain of his own yacht, to out-of-the-way spots in many parts of the world.

CRAWFORD, George Walker, American lawyer and public official: b. Columbia County, Ga., Dec. 22, 1798; d. July 22, 1872. Graduated from the College of New Jersey (now Princeton University) in 1820 and admitted to the bar in 1822, he opened a law office in Augusta, Ga., and served as attorney general of Georgia from 1827 to 1831. He was a member of the state legislature from 1837 to 1842, except for one year, and a Whig representative in Congress in 1843. In that year he was elected governor of Georgia and, re-elected in 1845, served until 1847. He was appointed secretary of war by President Zachary Taylor in 1849, but resigned after the president's death (1850) and retired from public life. In 1861, however, he served as chairman of the state's secession convention.

CRAWFORD, Isabella Valancy, Canadian poet: b. Dublin, Ireland, Dec. 25, 1850; d. Toronto, Ontario, Canada, Feb. 12, 1887. With her parents she emigrated to Canada in 1858 and lived in the Kawartha Lakes region, where her father practiced medicine. After his death she and her mother moved to Toronto, where she published poetry and short stories in newspapers. Her only book, *On the Spookiest Pass, Malcolm's Katie, and Other Poems*, appeared in 1884. Her poetry,

lyrical and rich in imagery, was inspired by the Ontario villages where she grew up. Her *Collected Works*, edited by J. W. Garvin, were published in 1905.

CRAWFORD, Thomas, American sculptor: b. New York, N. Y., March 22, 1813?; d. London, England, Oct. 10, 1857. Apprenticed at the age of 14 to a woodcarver, he later worked with the tombstone cutters Frazee & Launitz, and studied anatomy at the National Academy of Design. In 1835 he went to Rome carrying letters of introduction to Bertel Thorvaldsen, the Danish sculptor, with whom he studied. Crawford's earliest important independent work is the *Orpheus* in the Boston Museum of Fine Arts. There are three statues by him (*Genius of Mirth*, *Mexican Princess*, and *Babes in the Wood*) in the Metropolitan Museum of Art in New York, and the Washington Monument in Richmond, Va., is also his. By far his best-known works are the sculptures commissioned by the United States government for the Capitol in Washington, D.C., which he did not live to complete. These bronzes include the statue of *Armed Freedom* that surmounts the dome, the sculptures in the pediment of the Senate wing, and the pair of bronze doors of the Senate portico with bronze reliefs that contrast the terrors of war with the blessings of peace.

Consult Taft, Lorado, *History of American Sculpture* (New York 1903); Gardner, A. T., *Yankee Stonecutters* (New York 1945).

MARGARETTA SALINGER,
Metropolitan Museum of Art

CRAWFORD, William Harris, American lawyer and public official: b. Amherst County, Va., Feb. 24, 1772; d. Elberton, Ga., Sept. 15, 1834. He went with his family to South Carolina and then, in 1783, to Columbia County, Ga. After teaching school for a time, he studied with Moses Waddel, and then taught again in Augusta. In 1798 he was admitted to the bar and opened a law office in Lexington. He soon became interested in politics, and fought two duels (1802 and 1806) on political questions. In 1803 he was elected to the state legislature, and in 1807 to the United States Senate to fill a vacancy caused by the death of Abraham Baldwin. Re-elected for a full term, he was chosen president of the Senate pro tem. in 1812 on the death of Vice President George Clinton. He was appointed minister to France in 1813, and two years later became secretary of war, and in the following year secretary of the treasury, an office he held until March 1825. He was mentioned as a possible candidate for the presidency several times, and although he was stricken with paralysis in 1823, his friends put forward a plan to have him nominated by caucus. He received the nomination in 1824, and in the election was third among four candidates, with 41 electoral votes. Since none of the candidates had a majority, the election was decided in February 1825 by the House of Representatives, which chose John Quincy Adams. Crawford never wholly recovered his health, although he remained active in politics and served as a circuit judge in Georgia from 1827 until his death.

CRAWFORD NOTCH, mountain pass, New Hampshire, situated in Carroll County, west of the Presidential Range in the White Mountains. About five miles long, it is located

at an elevation of about 2,000 feet above the Saco River, which rises here. The pass was discovered in 1771, and the surrounding area was made a state forest in 1911. Its scenic beauty attracts many visitors.

CRAWFORDSVILLE, city, Indiana, seat of Montgomery County, situated at an altitude of 740 feet, on Sugar Creek, 43 miles west-northwest of Indianapolis. It is served by the Chicago, Indianapolis and Louisville, the Pennsylvania (freight only), and the New York Central railroads. The city is the trading center for an agricultural, livestock (pig and poultry), and dairying region, and has establishments processing food, and manufacturing wire and nails, brick and tile, culverts, shirts, coats, farm implements, lift trucks and skids, poultry roosts and brooders, caskets, and fences. There are also large printing houses.

Crawfordsville is the seat of Wabash College, a men's college founded in 1832. It was the home of Lew Wallace, author of *Ben Hur*, whose study has been preserved by the city as a memorial; of Henry S. Lane, United States senator in Civil War days; and of the novelists Meredith Nicholson and Maurice Thompson. Laid out about 1822, it became a city in 1865 and is governed by a mayor and council. The electric light plant and an airport are municipally owned. Pop. (1950) 12,851.

CRAWL. See **SWIMMING**—*Crawl*.

CRAYER, krá'yēr, Caspar de, Flemish painter: b. Antwerp, Spanish Netherlands, Nov. 18, 1584; d. Ghent, Jan. 27, 1669. A pupil of Raphael van Coxie, he became a member of the Guild of St. Luke in Brussels in 1607. There and in Ghent, where he spent his last years, he executed many works for the Spanish court, from which he received a pension. His paintings, which show the influence of Peter Paul Rubens, are found in many churches and museums in Belgium and elsewhere. Among them are *Christ on the Cross* and *Decapitation of St. John the Baptist* (Cathedral of St. Bavon, Ghent); *The Judgment of Solomon* and *Coronation of St. Rosalie* (Musée des Beaux-Arts, Ghent); an altarpiece, *Adoration of the Magi* (Aerschot); *Adoration of the Shepherds* (Brussels Museum); and *Alexander and Diogenes* (Metropolitan Museum of Art, New York).

CRAYFISH or **CRAWFISH** (Middle English *crevis*, from Old French *crevice*; Fr. *écrevisse*), a freshwater crustacean resembling a small lobster and unrelated to fish. Crayfish attain a length of three to six inches. The head, bearing one pair of long feelers, one pair of short feelers, a pair of stalked eyes, and some feeding appendages around the mouth, is completely fused with the thorax, which is provided with five pairs of walking legs, the first pair terminating in large defensive and aggressive claws (chela). This head-thorax region (cephalothorax) is distinctly separated from the jointed abdomen, which ends in a broad tail fin and bears on its underside swimming appendages or swimmerets, one pair to each joint.

Crayfish walk about, mostly at night, on their walking legs, but if alarmed give a sudden backward dart by flipping the tail fin under the abdomen. They eat almost anything, chiefly all kinds

of vegetation, but also animal food if available, and are generally regarded as scavengers. The sexes are separate and are easily distinguished by external anatomical differences. Mating occurs during the warmer part of the year. Before laying the eggs, the female cleans the abdomen thoroughly and exudes a sticky substance. Then, while lying on her back, she emits the eggs and glues them to the swimmerets. A female thus carrying eggs on her swimmerets is said to be in berry, and this condition is usually seen in spring and early summer. The eggs hatch after some weeks into tiny crayfish that remain with the mother for some time before taking off for a free existence. They molt several times before attaining the adult state.

Crayfish are aquatic, living in lakes, ponds, sloughs, and streams, mostly hiding by day under stones and coming out at night to feed. Some, however, inhabit swampy places and wet meadows that are not under water. Here they live in burrows constructed at night and marked by chimneys of mud thrown up around the entrance. They may be so numerous in poorly drained lands as to interfere seriously with agricultural processes. Some species are confined to cave waters, and these are small, slender, and translucent or whitish, with degenerated eyes (see also **CAVE ANIMALS**—*Blind Inhabitants*). About 130 species of crayfish are known in the United States.

For further information and extensive references on crayfish consult Pennak, R. W., "Decapoda," *Fresh-Water Invertebrates of the United States* (New York 1953).

L. H. HYMAN,
Department of Living Invertebrates, American Museum of Natural History.

CRAYFORD, urban district, England, situated in Kent, on the Cray River, 2 miles west of Dartford and 12 miles east-southeast of London. It is part of Greater London. Primarily a residential community, it also has flour mills, petroleum refineries, and plants processing wool. Points of interest include a pre-Norman manor and a 15th century church. Pop. (1951) 27,951.

CRAYON, Geoffrey, a pseudonym of Washington Irving (q.v.).

CRAYON, a pencil-like implement for marking or drawing, made of chalk, wax, or a combination of wax and clay (the so-called pressed crayon), and colored by the admixture of pigments. The chalk type is of ancient origin; it was used by most of the old masters in red, white, or black, and is now employed in a wide range of colors for pastel drawing. These crayons produce softer tone effects than oils or water colors. Their disadvantage lies in their physical delicacy. Because they smudge so easily, pastel drawings, to be preserved, must be kept under glass or sprayed with a fixative. Pastel crayons are made by mixing chalk and coloring materials with gum water to make a paste, which is then formed in the desired shape and dried. The wax varieties, developed in the latter part of the 19th century, are universally used in industry, in homes, and in elementary art courses, and are produced in by far the greater volume. Because of their widespread use by children, most wax crayons in the United States are now made entirely of non-toxic ingredients, and are so labeled. The most recent development is the wash-off

crayon, the composition of which is held to be a trade secret, but is generally understood to include the use of a soap base. A lithographic crayon is a black composition used for drawing on stones or plates for reproduction by lithography. It consists of soap, wax, resins, and lampblack, melted together. Crayon sticks are manufactured in various shapes, such as round, hexagonal, and square. Most, however, are made in the form of a cylinder, with the wax varieties usually encased in paper jackets.

CRAZY HORSE (Indian name TASHUNCA-UTCO), American Indian chief: b. about 1849; d. Fort Robinson, Nebr., Sept. 5, 1877. Little is known of his early life, but he probably fought with Red Cloud in Wyoming in 1866-1868. As chief of the Oglala tribe of Sioux, he was a leader in the Sioux War which broke out in 1876. This outbreak was due to several causes, chief of which was the occupancy of the Black Hills of South Dakota by white prospectors. The War Department had ordered the Indians to return to their reservations by Jan. 1, 1876, but Crazy Horse and his followers refused to do so. On March 17, Gen. Joseph J. Reynolds surprised the Oglala at their village near the mouth of the Little Powder River and destroyed it, but the Indians escaped and recaptured most of the ponies which had been taken away. In an engagement fought at Rosebud Creek on June 17, Crazy Horse, leading a force of about 1,200 Sioux and Cheyenne, compelled Gen. George Crook to retreat. He then strengthened his band with Indians from the various reservations, and others joined Sitting Bull in Dakota Territory. The two forces were joined on the Little Bighorn River in Montana, and there, on June 25, 1876, they annihilated the command of Gen. George A. Custer. For months thereafter the united bands held the country in terror. On Jan. 8, 1877, Col. Nelson A. Miles attacked Crazy Horse near the headwaters of the Rosebud, but he was able to retire with his band. Soon thereafter, however, the Cheyenne broke away, and Crazy Horse's remaining followers were constantly harried by the army. The pressure finally became so great that, on May 6, 1877, Crazy Horse surrendered with about 1,100 followers at Fort Robinson. Suspected of attempting to lead another outbreak, he was arrested on September 5 and, while attempting to escape, was fatally wounded.

CRAZYWEED. See LOCOWEED.

CREAGH, krā, SIR Garrett O'Moore, British soldier: b. Cahirbane, County Clare, Ireland, April 2, 1848; d. London, England, Aug. 9, 1923. Educated at the Royal Military College, Sandhurst, he became an ensign in the 95th Foot Regiment in 1866. Four years later he transferred to the Indian Army, with which he fought (1879-1880) in the Second Afghan War, receiving a Victoria Cross for bravery. He was stationed on the northwest frontier from 1884 to 1890, and in Aden from 1898 to 1900. In 1899 he was promoted to the rank of brigadier general. He commanded the 2d Brigade in the China Expedition in 1900, and the entire British expeditionary force in China in the following year, after which he returned to India. He was knighted in 1902 and became a major general in 1903, a lieutenant general in 1904, and in 1907, following his return to England, a full general. From 1907 to 1909 he

was assigned to the India Office, and then succeeded Lord Kitchener as commander in chief in India, remaining in this post until his retirement in 1914.

CREAM. See DAIRY PRODUCTS—*Milk*.

CREAM CHEESE. See CHEESE AND CHEESE MAKING; DAIRY PRODUCTS—*Cheese*.

CREAM NUT. See BRAZIL NUT.

CREAM OF TARTAR (also known as POTASSIUM HYDROGEN TARTRATE, POTASSIUM ACID TARTRATE, and POTASSIUM BITARTRATE), a white crystalline compound ($\text{KHC}_4\text{H}_4\text{O}_6$) which is not very soluble in water. At 0°C ., 0.37 grams will dissolve in 100 milliliters of water, and at 100°C ., 6.1 grams will dissolve in 100 milliliters of water. The specific gravity is 1.956. Potassium acid tartrate is formed when one of the two acid hydrogen atoms in dibasic tartaric acid is replaced by potassium; when both hydrogen atoms are replaced, potassium tartrate is formed.

Most tartrates are obtained commercially as byproducts of the wine industry, particularly from a certain variety of sour wine. Small quantities are also obtained from the grape juice industry. Tartrates exist in grapes as potassium acid tartrate, calcium tartrate, and, in small quantities, as free tartaric acid. When grapes are crushed and pressed, most tartrates remain in the juice. As the juice stands, crystals of tartrates called argols (see ARGOL) are formed and cling to the sides and the bottom of the container. Fermentation accelerates this process, but it is not absolutely necessary. From argols by repeated crystallization and decolorization with bone black, pure cream of tartar is prepared.

Cream of tartar's relatively low solubility, its acidity, and its edibility when pure make it a logical choice for the acid ingredient in the acid-soda type of baking powder (q.v.). It is widely used for this purpose in commercial baking powders, which contain sodium bicarbonate and cream of tartar in proportion to their molecular weights, and an inert material such as starch or flour to prevent premature reaction. Medically, cream of tartar is used as tartar emetic, which contains three parts of antimony oxide and four parts of cream of tartar, and as potassium borotartrate or soluble cream of tartar, which contains two parts of borax and five parts of cream of tartar. It is also used in calico printing and as a mordant in wool dyeing.

See also TARTARIC ACID.

PAULINE DIAMOND.

CREAM SEPARATOR. See CENTRIFUGAL; FARM MACHINERY—*Specialized Equipment*.

CREASY, krē'sī, SIR Edward Shepherd, English historian: b. Bexley, England, Sept. 12, 1812; d. London, Jan. 27, 1878. He was educated at Eton College and at King's College, Cambridge University, of which he became a fellow in 1834. Three years later he was called to the bar at Lincoln's Inn, and for several years was a member of the home circuit (London and vicinity). In 1840 he was appointed professor of history at the University of London, and in 1860 was knighted and made chief justice of Ceylon. Because of ill health he returned to England in 1870. Although he was able to resume his post,

he again became ill and retired within two years. Creasy is known chiefly for his *Fifteen Decisive Battles of the World* (q.v., 1851), a work which passed through many editions. He also published *Historical and Critical Account of the Several Invasions of England* (1852); *The History of the Ottoman Turks* (1854-1856); *History of England* (2 vols., 1869-1870); and *Imperial and Colonial Institutions of the British Empire, Including Indian Institutions* (1872).

CREATINE and **CREATININE**, organic nitrogen compounds closely related chemically and biologically. Creatine is found in the tissues of higher animals, while creatinine is an end product of their metabolism. Both are related to amino acids (q.v.). Creatine is alpha methyl-guanidinoacetic acid, $\text{HN}=\text{C}(\text{NH}_2)\text{N}(\text{CH}_3)\text{CH}_2\text{CO}_2\text{H}$, and creatinine is its anhydride derivative, $\text{HN}=\text{C}-\text{N}(\text{CH}_3)\text{CH}_2$.

Creatine may be synthesized from sarcosine, $\text{CH}_3\text{NH}-\text{CH}_2\text{CO}_2\text{H}$, and cyanamide, $\text{H}_2\text{N}-\text{CN}$. It is a crystalline solid and is sparingly soluble in water (1.5 per cent at room temperature). It is much more of a dipolar substance than any amino acid. Guanidine and its alkyl derivatives are strong bases; hence creatine is about 1,000 times as strong a base as it is an acid. Creatine is present in the human body to the extent of 90 to 120 grams (or 300 to 400 milligrams per 100 grams of tissue), 98 per cent of it being in muscles. Approximately 80 per cent of creatine is combined with phosphoric acid as phosphocreatine, an unstable addition product. This combination is of great importance in muscular activity, being broken up with the evolution of energy and re-formed when the muscle is in repose. Contrary to earlier theories that all amino acids could produce creatine, it is now generally believed that it is formed by the interaction of glycine, arginine, and methionine. This conclusion is supported by researches employing the heavy isotope of nitrogen, N^{15} . Creatine is probably formed mainly in the muscles, and is not merely a waste product of protein metabolism.

Creatinine is formed from creatine in acid solution with the loss of water. In water solution with a pH between 5 and 7, creatine and creatinine exist together in equilibrium in equimolecular quantities. Creatine forms a characteristic picrate which is sparingly soluble in water, and whose characteristic yellow color changes to an orange red in the presence of an alkali. The creatine picrate is soluble. Creatinine is present in the animal body in much smaller quantity than creatine, 100 grams of skeletal muscle, for example, containing from 300 to 500 milligrams of creatine and only 10 milligrams of creatinine. The latter is about equally distributed between cells and plasma. While there is relatively little creatinine in the tissues, it is regularly found in the urine, being an end product which the animal body cannot utilize. This is demonstrated by an experimental procedure in which creatinine is labeled with N^{15} and administered to an animal, and all of it is recovered from the urine. On the other hand, creatine similarly labeled is not found in the urine unless the dosage has been very large. When creatine is found in the urine of adult males, it is usually an indication of some sort of abnormal condition such as disturbances in phosphorus metabolism. It is commonly present in

the urine of children, however, and in that of women in pregnancy and during lactation. Creatinine is the next most abundant of nitrogen compounds in urine, an adult male secreting from 1.0 to 1.5 grams per day.

The so-called Folin coefficient is based on the assumption that creatine excretion is constant, and is the amount in milligrams excreted per hour divided by the body weight in kilograms. In men this value is between 20 and 26, except for athletes, whose coefficient is around 30, while for the average woman it is between 14 and 22. The coefficient is thus definitely related to muscular development. Creatinine concentration in the blood is a sign of the status of nonprotein nitrogen excretion.

W. T. READ,
*Chemical Adviser, Research and Development
Division, General Staff, Department of the
Army.*

CREATION (Lat. *creatio*, from *creare*, to create). The doctrines of creation in the various religions of the world are those which describe or explain the origin of the universe, the earth, and man upon it. Most of them appear to represent inferential thinking based on the nature of existence as it is expounded by the several religions, and they furnish the setting in which human life and society are comprehended. Generalizations on such a complex subject are bound to be oversimplifications to which exceptions can be made. Yet it would appear possible to say that a basic difference in views of creation can be observed between those religions in which the superhuman is understood as immanent in the natural process and those in which it is transcendent.

In the ancient polytheisms the universe was considered as alive, and the gods were personifications of elements, forces, and principles which alone explained movement, activity, process, order, and disorder. From such a point of view the gods are immanent within the order of things, and the doctrine of creation is depicted by myths which describe how the present order was achieved and what the place of human society is within it. In the ancient Middle Eastern polytheisms, for example, thought did not and could not reach behind the primordial, static chaos which was envisaged as the dark and watery deeps, or primeval ocean from which the salt and fresh waters come. In Mesopotamia the deeps were personified, and creation was represented as beginning with a process of sexual procreation, producing a series of gods who were the various elements of the universe as then understood. Order was achieved after a cosmic battle in which the younger and active forces won a victory over the static chaos and proceeded to establish world order. Man was created as the slave of the gods to do the menial work of the earth. Life, however, is an uncertain thing, and the creation battle among the forces of nature, while it issued in the initial victory, had to be refought and rewon each year.

The essentials of this view seem also to have been held in Canaan (Syria-Palestine), where the creation was described as a battle between the king of the gods and the primordial dragon of chaos, called Leviathan (Lotan) or Yam (sea). In Egypt the same once-for-all, and yet yearly, and daily, battle was waged by the sun against the dragon of chaos and darkness. Yet in Egypt

life was not seen as so precarious; victory was always assured; society and world order were static and rhythmic, and fixed in the order of creation. Hence other approaches to creation were made which emphasized the fullness of the present order, such as the emergence from the ocean of chaos of the primeval hill on which the sun, the primeval king, began the creation by procreation.

In religions and philosophies evolving from this polytheistic base the tendency was to demythologize the myths and to think in terms of an abstract principle or principles which had infinite existence as the explanation of world order. Thus in Greece various ideas of the basic principle underlying the evolution of the universe were discussed, whether it was water, fire, air, mind (nous), or desire. Yet in every case the principle or principles involved in the creation informed or reshaped a pre-existent entity. In Chinese Taoism creation is the emergence of all things through the activity of Tao, the latter being the substance of life which pervades all living things. Antedating Taoism were the principles of yang (the positive) and yin (the negative), whose interaction created life. In classical Buddhism and Hinduism, however, there is actually no doctrine of creation because the reality of the world as we see it is an illusion, and the only true reality is the incomprehensible and unknowable essence to which the Buddhists refer as nirvana and the Hindus as Brahma. Yet this essence is scarcely transcendent; it is immanent in every being, and if one can speak of a doctrine of creation at all, it would be in terms of the discovery of self.

In Jewish and Christian thought, however, insofar as it is based on the Bible, there is an emphasis on an independent, self-existent Deity Who transcends all that exists and thus is the source or Creator of all that is. Instead of the personification of elements or principles within the universe who can create only by achieving a harmony of wills, as in polytheism, Biblical faith projects a single Deity Who as Creator is utterly distinct from the creation, and as Ruler is not the ruled. ("To whom then will ye liken God? or what likeness will ye compare unto him?" Isaiah 40:18.) Israel had evidently arrived at this view of ultimate power through an interpretation of what had happened in her national life: that is, through an interpretation of historical events. This God had met Israel in history, had delivered her from Egyptian slavery, had formed her into a nation with an order of life provided in a covenant, and had given her a good land in which to dwell. In doing so He had revealed His complete power over all forces of nature and history, and had revealed as well a purpose to be observed in events. Hence Biblical faith was exhibited in the forms of historical tradition.

The creation stories in Genesis 1:1 to 2:4 and the following verses evidently represent a reworking of older materials, the chief purpose being to depict the complete dependence of all that is on God the Lord. Since His power controls all history, what exists springs from Him. As Lord of history, He is the Creator of history, of time, and of nature, which is the arena of history. At this stage of Biblical thinking the independent and self-existent Deity is represented as acting on a pre-existent chaos, but the stage is set for the later assertion that He was the Creator

even of the chaos and had created from nothing (compare II Maccabees 7:28).

The Biblical emphasis on God's relation to history is further reflected in the conception of human life presented in the creation stories. Man was conceived as the greatest of God's creative acts and given the task of ruling over the earthly dominion. The account of creation thus involved a high estimate of the dignity of man and his historical vocation. Freedom of mind and will were given to enable him to fulfill his task and to accept his creaturehood as a service of God in a divinely given vocation. His trouble on earth, however, as Genesis 3 and following chapters point out, results from his refusal to accept his creaturehood in this sense and his use of his freedom to grasp at equality with his Creator and Lord. This he cannot achieve, and the miseries of his existence are interpreted as his punishment. That man is created "in the image of God" (Genesis 1:26-27) thus does not mean that a portion of divine substance (or a spark of the divine) resides in him. God has preserved his independence. Instead, it refers to the dignity, freedom, and royal vocation given man to rule the earth as God rules His universe (compare the 8th Psalm, a poetic interpretation of Genesis 1), while at the same time it points to that in man which enables him alone among all living creatures to live in communion with his Maker. CREATIVE EVOLUTION (Fr. L'ÉVOLUTION CRÉATRICE), a philosophical work of great poetic power by Henri Bergson (q.v.), first published in Paris in 1907 and translated into English in 1911. A reaction from the sweeping claims made for science by Herbert Spencer, it is an attack on the competence of the intellect. Bergson's object is to vindicate the spiritual principle in nature and to assert the superior competence of intuition (q.v.). The intellect, completely at home in a world of inert matter where its principal use is to fashion tools out of solids, is not competent to deal with life and thought because it instinctively treats them as though they too were solids. The intellect treats time in the same way, as though it were a solid, dividing it into a series of separate, successive moments. Real time is beyond the grasp of the intellect; only the intuition can comprehend its smooth, continuous change without division. Bergson objects to the usual concept of evolution because it deals exclusively with the products of evolution, mistaking them for the evolutionary process itself. True evolution is a continuous creation in which an *élan vital* (vital impulse) pushes outward from inside every being, whether plant, animal, or man, in an effort to achieve perfection and freedom. This vital impulse is the source of the energy which impels a being to improve itself and to push over any obstacle which bars the way. It may be diverted or stopped, but the vital impulse is the source of all evolutionary change. Every action and response a being makes is part of its evolutionary process, and a recognition of the vital impulse, obtainable only through the intuition, allows higher beings to direct it fruitfully. The principal objection made to the theory of creative evolution is that its use of a mysterious vital impulse and its substitution of intuition for intellect lead to mysticism. Bergson fore-

saw this danger and denied that it was inevitable. See also BERGSONISM.

CREBILLON, krā-bē-yōn, **Claude Prosper Jolyot de**, French novelist: b. Paris, Feb. 14, 1707; d. there, April 12, 1777. He was the younger son of Prosper Jolyot de Crébillon (q.v.), and succeeded as an author in an age of licentiousness. For his theological allusions in his novels, especially concerning the papal bull *Unigenitus*, he was imprisoned in the Bastille and banished from Paris for five years. By the subtleties with which he excuses licentious principles, Crébillon contributed to diffuse a general corruption of manners, before confined to the higher circles of Parisian society. His own morals, however, appear to have been the opposite of those which he portrayed, and we are told of his cheerfulness, his rectitude of principle and his blameless life. He married Lady Stafford, an English woman, to whom he displayed a fidelity remarkable at this decadent period. Of his works the best are *Lettres de la Marquise* (1732); *Tanzai et Néadarné* (less licentious, but full of now unintelligible allusions); *Les égarements du cœur et de l'esprit* (1736); *Le Sopha* (1745). It is still a disputed point whether he was the author of the *Lettres de la Marquise de Pompadour*. Consult Amanton, C. H., *Particularités sur les deux Crébillon* (Paris 1835).

CREBILLON, Prosper Jolyot de, French dramatist: b. Dijon, France, Feb. 15, 1674; d. Paris, June 17, 1762. His first piece, *La Mort des Enfants de Brute*, was rejected by the players. His *Idoménée* was brought upon the stage in 1705. The faults of the play were overlooked in consideration of the youth of the author and the promising talent which it displayed, and his talents after the appearance of his *Atrée*, in 1707, were loudly applauded. A taste for unnatural declamation had been excited by Corneille's tragedy, *Rodogune*, and this manner was carried to excess by Crébillon in the *Antrée*. In 1709 appeared his *Electre*, which is as declamatory and as intricate as his earlier plays; yet it suited the taste of the age. His *chef-d'œuvre*, at least according to La Harpe, is his *Rhadamiste* (1711). In eight days the *Rhadamiste* passed through two editions, and Paris and Versailles vied with each other in admiring it. Crébillon had been told that his talent lay in the terrible, and thought, therefore, that he could not exert himself too much in scenes of horror. *Xerxes* (1714) exceeded in this respect all that he had before written, but soon disappeared from the stage. *Semiramis* (1717) was severely censured, but *Pyrrius* appeared in 1726 and met with a good reception, contrary to the expectation of the author, who, in this work, had abstained from the frightful and the shocking. When Madame de Pompadour wished to humble Voltaire, Crébillon was thought of as a fit instrument for her purpose. The king gave him the office of censor of the police, a yearly pension of 1,000 francs, and an appointment in the library. Thus freed from pecuniary anxiety, he finished his *Catiline*, which was represented in 1749 with all the pomp that the court theater could display. To make some atonement to the character of Cicero, thought to have been wronged in his *Catiline*, he wrote at 76 the *Triumvirate, or the Death of Cicero*, which was

brought upon the stage in his 81st year. The defects of this piece were overlooked, from respect to the age of the author. In general Crébillon shows none of the true elevation of the tragic art, but only an imitation, sometimes a happy one, of the manner struck out by Corneille. He was a man of a proud and independent character, disdained to flatter the great, and passed much of his life in a condition bordering on poverty. In 1731 he became a member of the Academy. His works were edited best by Didot (1812). There is a Life by the Abbé de la Porte, and a fine essay by Brunetière in *Époques de théâtre français*.

CRECHE, krāsh (Fr. "crib," "manger"), a sort of public nursery where, for a small payment or, as in America, usually for nothing, the children of women who have to go out to work are fed, nursed and taken care of during the work hours of the day.

CRECY-EN-PONTHIEU, krā-sē ōn pōn-tièy, or **CRESSY**, a village in the French Department of Somme, on the Maye, 12 miles north of Abbeville. Crécy has a 15th century church and is celebrated on account of the brilliant victory obtained here, Aug. 26, 1346, by Edward III, with 40,000 English soldiers, over a French army amounting, according to Froissart, to 100,000 men under the command of the Count of Alençon. In this great battle perished the flower of the French chivalry, as well as the blind king of Bohemia, who was fighting on the side of France. The Black Prince distinguished himself greatly, bore the brunt of the fight, and gained his spurs. After this battle, tradition says, the Black Prince assumed the crest of the slain king of Bohemia, which consisted of three ostrich feathers with the motto *Ich dien*, "I serve," but this is more than doubtful. The Battle of Crécy was one of the first in which cannon were used by English troops. Pop. about 1,400. Consult George, *Battles of English History* (New York 1895); and Oman, *History of the Art of War* (London 1898).

CREDENCE, a small table placed near the altar or communion table, at its south side, on which the bread and wine intended for consecration are placed in readiness. In this connection it is used especially in the Roman Catholic and Episcopal churches. In the Greek Church this is called the *trapeza protheseos*, or simply *prothesis*, but is always placed north of the altar, usually in a structural side-chapel. It was sometimes used in the English Church. The word is generally used to denote a small side table or buffet, on which dishes were placed or kept before meals.

CREDI, krā'dē, **Lorenzo di**, Italian artist: b. Florence, 1459; d. there, Jan. 12, 1537. He was a fellow pupil of Leonardo da Vinci in the school of Verrocchio, and so closely followed his style that some of his copies of Leonardo's works are scarcely to be distinguished from the originals. His *Holy Families*, of which he painted a great number for private collections, are gracefully designed and highly finished. His most esteemed works are a *Madonna and Child with Saints Julian and Nicholas*, now in the Louvre, and the *Nativity* at Florence. Two very fine works are the *Annunciation* and

the *Venus* in the Uffizi Gallery in Florence, Italy. The Metropolitan Museum of Art in New York has a *Madonna Adoring the Christ Child*, and in the Gardner Museum of Art in Boston, Mass., there is a beautiful boy's head. Credi also did some sculpture and was designated by Andrea del Verrocchio to complete his Colleoni Monument.

CREDIT, Economic. The word *credit* is derived from the Latin base meaning "faith" or "trust." In economics and finance the term is used specifically to refer to the faith placed by a creditor (lender) in a debtor (borrower) by extending a loan to the debtor. In a modern, complex market economy, the loan is usually in the form of money. When a loan is made, the lender extends credit to the borrower, while at the same time accepting the credit of the borrower. A market economy, such as exists in the United States, could not function without extensive use of credit based almost exclusively upon the faith and trust of the participating buyers and sellers. In addition, the existence of readily salable commodities or collateral in the hands of the borrower tends to increase the amount of credit which may be extended to him by adding to his means of repayment.

Credit performs two primary functions. The first consists in facilitating the transfer of capital or money, thereby increasing the productivity of capital by placing it where it will be most effectively and efficiently used. The second function is that of economizing on the use of currency or coin money.

A highly developed credit system is necessary for the widespread use of credit. The credit system functions for the purpose of facilitating the transfer of credit instruments, as well as for the extension of credit. Credit instruments take such forms as promissory notes, bonds, and bills of exchange. A check is a specialized type of bill of exchange. In order to perform their function of transferring credit adequately, credit instruments must be fully and readily negotiable. Negotiability depends upon acceptability, and acceptability in turn depends on the faith which constitutes the ultimate basis of credit. (See also **COMMERCIAL PAPER**.)

An actual loan need not be made for credit to be utilized in economic activity. Credit supplies the modern world with the bulk of its media of payment, or money. Bank demand deposits or checking accounts constitute the largest segment of the money supply of the United States, and over 90 per cent of the dollar volume of money payments in the United States is accounted for by checks. Checking account deposits are simply liabilities of commercial banks, and only the universal acceptability of bank credit permits them to function as money. In addition, virtually all of the paper money in the United States, which comprises all but a negligible portion of the total currency in circulation, is credit money. Each bill is simply a promise to pay by the United States government or by one of the Federal Reserve banks. The faith of the general public in the ability of the issuer to make good its promise on demand is the foundation of the bulk of the money supply in the United States.

Bank credit is a peculiar feature of a highly organized market economy. Because commercial banks serve clearing houses for the financial transactions of many persons and businesses, the credit of a bank is accepted in many instances

where that of an individual or private business would not be. A commercial bank can also create credit, and hence money. When a commercial bank lends money, it sets up a checking account in the name of the borrower for the amount of the loan, thereby substituting its own credit for that of the borrower. The important difference is that commercial bank credit is more generally acceptable and functions as money.

Various kinds of credit institutions have been developed to handle the specialized problems of such different types of credit extension as consumer installment borrowing, real estate mortgages, and government bonds. This specialization has further expanded the use of credit in the United States, with the result that greater development of organized markets and of large-scale enterprise has been possible.

CREDIT, Letter of, an order given by bankers or others at one place to enable a person to receive money from their agent or agents at another place. When the letter or notification is addressed to the person who is to receive the credit and authorizes him to draw up to a certain sum, it is called a *commercial or confirmed letter of credit*; when the letter is addressed by the original banker to a correspondent or agent, it is called a *traveler's letter of credit*; and when the document is an order on more than one person or firm, it is known as a *circular letter of credit*.

CREDIT INSURANCE. See **INSURANCE, CREDIT.**

CREDIT MOBILIER, krâ-dê mô-bê-lyâ'; Eng. kréd'it mô-bê-lyê', a large company founded in France in 1852 by Jacob Émile Pereire and Isaac Pereire and sanctioned by the then existing government. Incorporated under the name of Société générale du crédit mobilier, the company's object was to advance new industrial enterprises through loans and the purchase of stock. It bought shares in public companies and paid demands upon it with its own shares. At the time of its formation the company had a capital of 60 million francs and soon was doing an extensive business. In 1855 the directors proposed to issue bonds to the amount of 240 million francs, but so large an issue aroused public alarm and the scheme was forbidden by the government. The prosperity of the company, which gave important help in developing the industry of France,

declined after this time, and in 1871 the management was changed.

CREDIT MOBILIER OF AMERICA, the cause of one of the most serious legislative scandals in American history. The United States government in 1864 granted a charter to the Union Pacific Railroad (q.v.), with a capitalization of \$100 million, to complete a transcontinental line west from the Missouri River, and offered to assist it by a loan of \$16,000 to \$48,000 a mile according to location and a land grant of 20 million acres, the latter worth \$50 million to \$100 million. Even this offer attracted few subscribers, since the project meant building hundreds of miles of road through mountains and deserts, at an enormous cost of freightage for supplies, amid frequent bloody encounters with the Indians, and with no probable early return on investment. Shortly thereafter, a House committee, of which Representative Oakes Ames of Massachusetts was a member, added an authorization to the railroad to issue its own bonds dollar for dollar with the government's, the former to be first mortgage bonds and the latter second. In other words, the government assumed all the risk.

The stock of the railroad, nevertheless, had no marketable value in its own right as an investment, but only through the government's offers to pay in excess of the probable cost, which made it worth while for capitalists to take up the stock and earn these offers. Ames, also a director of the railroad, and a few associates knew that the cost of the undertaking would not come to the full amount of the government's loan and gift together. To gain possession of the balance, they decided to form the stockholders of the Union Pacific into a duplicate corporation under another name. This corporation would actually construct the railroad, and to it the railroad company would turn over its bonds and stocks as payment for work and supplies. In March 1864 an inner circle of the railroad bought up a moribund Philadelphia concern called the Pennsylvania Fiscal Agency, which had been originally chartered in 1859, and the Pennsylvania legislature authorized the new name, *Crédit Mobilier of America*. Union Pacific stockholders took the same amount of stock in the construction company as in the railroad.

In 1866 the government extended its offer of grants to such mileage as the Central Pacific should build east from its California lines, and the two companies began a race to secure the benefits. Probably the *Central Pacific* gained as much profit as the *Crédit Mobilier*, but its profits were legitimately earned for its stockholders. Even the *Crédit Mobilier*'s action would not have been so unsavory if the collusion between government directors and public representatives had not occurred. By the time the railroad was completed in 1869, the *Crédit Mobilier* had accumulated huge profits while the Union Pacific Railroad was greatly in debt. The report of the trustees of *Crédit Mobilier* stated that they had realized a profit of about \$23 million, but this was definitely an understatement and did not cover the full period of operations.

In the midst of the undertaking the promoters began to quarrel bitterly over the division of spoils, and outsiders demanded a share in the profits as the price of silence or assistance. Representative Elihu B. Washburne of Illinois moved an investigation and the fixing of transportation

rates, and in alarm Ames took out 343 shares of *Crédit Mobilier* stock, then commanding a 100 per cent premium, and sold at least 160 of these shares at par to congressmen and other leading government officials. In a phrase that became classic, he said that he would put the shares "where they will do most good. . . ."

In the latter part of 1867 the quarrel of an outsider, Col. H. S. McComb, with Ames laid the mine for the final explosion. McComb asserted his right to 375 shares, and to quiet him Ames told him the names of the public men to whom he had "sold" the stock. McComb bided his time and during the presidential campaign of 1872 filed affidavits alleging the misuse of the stock by Ames. On Sept. 4, 1872, the *New York Sun* published the letters of Ames to McComb which gave the names of those supposedly implicated in these dealings. The list included among others the names of such prominent men as Schuyler Colfax, the vice president of the United States and formerly speaker of the House; Henry Wilson, the vice president-elect and a senator from Massachusetts; James G. Blaine, the speaker of the House; James W. Patterson, senator from New Hampshire; James Brooks, representative from New York; and James A. Garfield, representative from Ohio.

When the third session of the 42d Congress opened in December 1872, Blaine descended to the floor of the House and demanded a committee of investigation; a committee was appointed with Luke P. Poland of Vermont as chairman. The Poland Committee made a report on Feb. 18, 1873, which established the fact that the speaker had been offered stock but had refused to touch it, as had Roscoe Conkling, James A. Bayard, and George S. Boutwell. Other officials had taken the stock but had returned it when lawsuits were threatened, without retaining the dividends; some had kept the stock and had justified their action as a sound business investment; others had kept the stock and the dividends until investigation was imminent; and a few had kept both the stock and the dividends and had attempted to deny or explain away their ownership. The report of the committee recommended the expulsion of Representative Ames and found him "guilty of selling to members of Congress" shares of the *Crédit Mobilier* at prices below their value, with the intent "to influence the votes and decisions of such members in matters to be brought before Congress for action." The committee also recommended the expulsion of Representative Brooks, a government director of the Union Pacific, for using his position to obtain stock for himself and his family. The report of the Poland Committee further stated that Colfax and Garfield had been directly involved and had received financial gain, although both men had previously testified to the committee that they had had no connection with the dealings. The vote in the House on the Poland report, however, was deferred for a week, and the House merely censured both Ames and Brooks, both of whom by a strange coincidence died shortly after, only a week apart. In the Senate an investigating committee recommended the expulsion of Senator Patterson, but no action was taken since the session was shortly to end. These revelations, together with other unsavory events of the first Grant administration, put the Republican Party on the defensive in the election of 1872; nevertheless, the scandal had little effect then on

Grant's popularity and he was re-elected by a plurality of over 700,000.

B., *The Crédit Mobilier of America* (Boston 1880); Hazard, Rowland, *The Crédit Mobilier of America* (Providence 1881); Rhodes, James Ford, *History of the United States*, vol. 7 (New York 1906); Oberholtzer, E. P., *History of the United States Since the Civil War*, vol. 2 (New York 1922).

CREDITON, kréd'i-t'n, village, Devonshire, England, is located about 8 miles northwest of Exeter. Formerly called Credington, Cryditon, and Kirton, the town is situated on the river Creedy near its junction with the Exe. It is usually thought to have been the birthplace of St. Boniface. From 909 to 1050, Crediton was the seat of a bishopric which was later moved to Exeter. The region around Crediton has long been famous for its spinning and weaving, in wools and also in fine lace. The most distinctive landmark of the town is the old Norman church. The old grammar school was founded by Edward VI. Pop. (urban district, 1951) 3,992.

CREE INDIANS, a tribe of North American Indians of Algonquian stock (q.v.) now settled on several reservations in Manitoba but formerly living in a region ranging from the southwestern borders of Hudson Bay southward and westward to the area about Lake Winnipeg and the Saskatchewan River. Before the arrival of white men, the Cree were settled only near Hudson Bay; later certain groups moved southward onto the prairies, thus forming two major divisions in the tribe, the Woodland or Swamp Cree to the northeast and the Plains Cree on the prairies. The Cree have traditionally been on friendly terms with the Assiniboin and with the French and English, but until brought under government control, they were constantly at war with the Sioux and Blackfoot Indians. Their culture is typically that of the eastland woodland, and they have a reputation as shrewd traders.

CREEDS AND CONFESSIONS (Lat. *credo*, I believe; *confessio*, I confess), formularies of doctrine, articles of belief, or affirmations of faith, for subscription or public use, setting forth with authority dogmas regarded by Christian churches as essential to the Christian faith.

The familiar confessional formulary common throughout nearly all Western Christendom is the Apostles' Creed (*Symbolum Apostolorum*), so called because of the widespread medieval assumption that it was composed by the 12 apostles. Renaissance scholarship initiated an attack upon the authenticity of this ancient tradition, and in time virtually all Christians have come to regard the tradition as a pious legend. The creed may still be properly linked with the apostles, however, because its teaching reproduces the authentic apostolic doctrine of the primitive Christian church. The precise form in which the Apostles' Creed is now used dates from the early years of the 8th century, but it is clear from the creeds quoted by Tyrannius Rufinus about 404 and by Marcellus of Ancyra, 60 years earlier, that the 8th century form is only a more mature variant of the ancient baptismal creed of the Roman church. Its ancestry, therefore, can be traced back through the baptismal interrogations of Hippolytus in the 3d century to the "rule of faith" in the writings of Tertullian, Irenaeus, and other church fathers still earlier. Substantially all the affirmations of the Apostles' Creed are found in the 2d century

expansions of the brief creedal forms present in the New Testament itself (Mark 8:29; Acts 8:36-38; Romans 10:9; 1 Corinthians 12:3).

The more developed theological formulary known as the Nicene Creed, commonly used in the liturgies of Eastern Orthodoxy and the Western Catholic churches, was put forth in its earliest form by the bishops assembled in the ecumenical Council of Nicaea in 325. A revision of older creeds by the addition of phrases that dealt authoritatively with the doctrinal disputes of the early 4th century, the Nicene Creed is current today in the more elaborate form given it by the Council of Constantinople in 381 and affirmed by the Council of Chalcedon in 451. Thus bearing the authority of the ecumenical councils, the Nicene Creed in its ancient form has remained the doctrinal standard of Eastern Orthodox churches.

Since the 9th century the Nicene Creed as recited in Western Christianity has differed from the older and Eastern Orthodox form by the use of the term *filioque*, meaning "and the Son." The introduction of this phrase as early as the Spanish Council of Toledo in 589 witnesses to the belief of Western theologians that the Holy Ghost proceeds "from the Father and the Son." This doctrine gradually spread throughout the West, and the use of *filioque* was by the 9th century the subject of such controversy between Constantinople and Rome that it contributed to the ultimate separation between the Orthodox East and the Catholic West.

A third important creed was the Athanasian Creed, which was derived from an exposition of the Nicene Creed and states, in 40 theses, the doctrines of the Trinity and the Incarnation. St. Athanasius was undoubtedly not its author, and probably the creed was of Western origin, perhaps from before the time of St. Augustine.

Eastern confessions or theological articles have been issued from time to time, the most controversial being the Confession of Faith of 1629, ascribed to Cyril Lucaris. Containing evident signs of Western Protestant (Calvinist) influence, this confession was condemned by the Synod of Jerusalem in 1672. Of more lasting importance are the "Symbolic Books" of Orthodoxy, consisting of the Confession of Gennadius II (Georgios Scholarios), 1453, an exposition of the Orthodox faith for Moslems; the Answers of Jeremiah II, 1576-1581, containing the replies of the patriarch of Constantinople to overtures from Lutheran theologians; the Confession of Metrophanes, 1625; the Orthodox Confession of Peter Mogila, 1640-1643; and the Confession of Dositheus, 1672, all of which set forth the teaching of Eastern Orthodoxy as compared with the doctrines of Western churches. While these documents lack the authority of the ancient ecumenical councils, they are received in Eastern churches with great respect because they are considered to express doctrine consonant with the conciliar decrees and the teaching of the fathers.

The period of the 16th century Reformation (q.v.) saw the appearance of numerous confessions and articles of belief setting forth the doctrinal position of Reformation churches. The basic Lutheran articles were published in the Augsburg Confession (*Confessio Augustana*), drawn up by Philipp Melanchthon, revised by Martin Luther, and presented to the Emperor Charles V at the Diet of Augsburg in 1530. Other documents of Lutheran confessional theology are Melanchthon's *Apologia Confessionis*

Augustanae; the Schmalkaldic Articles and the Wittenberg Concord of 1536; the Wurttemberg Confession of 1552; and the Formula of Concord promulgated in 1580.

Among the Reformed confessions (Zwinglian or Calvinist), as distinguished from the Lutheran, are the Tetrapolitan Confession (The Confession of the Four Cities--Strassburg, Constance, Memmingen, and Lindau), drawn up by Martin Bucer in 1530; John Calvin's *Consensus Tigurinus*, 1549; the Gallican, Scots, and Belgic confessions, 1559-1561; and Heinrich Bullinger's second Helvetic Confession of 1566, which reflected the doctrinal agreement reached earlier between Zwinglians and Calvinists, and assumed international significance among the Reformed churches. In 1646 the Westminster Confession was drawn up as the authoritative set of doctrinal articles for English and Scottish Presbyterians.

The course of Reformation thought in the Church of England may be traced through the conservative articles published in the reign of Henry VIII, of which the Ten Articles of 1536 and the King's Book of 1543 are the most important; the Forty-Two Articles of 1553, revealing the extent of continental Protestant influence in England in the reign of Edward VI; and the Thirty-Nine Articles of 1563 (revised 1571), reflecting the position of the Elizabethan church in respect to certain doctrines prominent in the controversies of the 16th century.

Confessional theology was characteristic of Roman Catholic intellectual activity in the Reformation period, and Counter Reformation (q.v.) articles are found in the decrees of the Council of Trent, promulgated by Pius IV in 1564 together with the Tridentine Profession of Faith, sometimes called "The Creed of Pius IV." To these summary statements of the distinctive features of the doctrinal system of the Church of Rome should be added the dogmas of the Immaculate Conception of the Blessed Virgin, declared in 1854; of Papal Infallibility, decreed in the Vatican Council of 1870; and of the Assumption of the Blessed Virgin, promulgated in 1950.

Theological Seminary, New York.

CREEKS, one of the most important confederacies of American Indians living north of Mexico. At one time the Creeks occupied the greater part of the present states of Georgia and Alabama and constituted one of the two largest divisions of the Muskogean linguistic stock to which they also gave their name.

When South Carolina was settled by the English in 1670, that section of the Creek Indian tribe later known as the Lower Creeks was living principally on the upper course of the Ocmulgee River, then called by the white colonists Ochee Creek. The Indians there came to be known to them as Ochee Creek Indians, and later this name was simplified to Creeks. The

name Muskogee, Muscogee, or Muscogulgee later applied to them seems to have been given by Shawnee Indians and designates a swampy country or one filled with creeks.

The Muskogee proper who formed the nucleus of the confederation consisted of a number of related tribes including the Coosa, Coweta, Kasihta, and several others, which were increased in later times by the addition of the Alabama, Koasati, Hitchiti, and fragments of the Yamassee and Natchez of the same linguistic family, the unrelated Yuchi (or Uchee), and, temporarily, bands of Shawnee. In the 18th century, some of the Creeks moved into Florida and became the nucleus of the Seminole ("Out-settlers") who were later increased by further secessions, particularly after the Creek War of 1813-1814.

Early estimates indicated a Creek population of 10,000-12,000, with possibly 3,000 warriors. This number was increased by additions from other tribes to about 20,000 in 1833 just before the removal of the Creeks west of the Mississippi River, and the increase came in spite of defections to Florida. When they moved to what is now Oklahoma, the Creeks became reduced to about 12,000, not including freedmen. In 1945 approximately 9,900 Creeks were reported to be living in Oklahoma and subject to government supervision.

Except when fortified in time of war, each Creek village in the region of original settlement consisted of a neighborhood of widely scattered houses. Each family usually had two houses. The winter house was circular and thatched with bark or grass, and around the inner wall ran a raised platform upon which the occupants slept at night warmed by a central fire. In summer the Creeks lived in oblong buildings ranged, if there were more than one in a group, around an open fireplace. Usually the summer ceremonial ground contained four cabins in which chiefs, warriors, and commons were seated in accordance with their rank.

A few Creek tribes were mentioned by the chroniclers in the expedition of Hernando de Soto, and the foundations of the confederation may have been laid by then (1540), although this fact is uncertain. In the late 17th and early 18th centuries, the Creeks found themselves confronted with settlements of three different European nations on their borders, and, especially under the clever strategy of a semidictator, the mixed-blooded Alexander McGillivray, they learned how to play off one nation against another. The possibility of such manipulation was practically ended by the withdrawal of France from North America and the cession of Florida to England by Spain in 1763. When the American Revolution broke out the Creeks sided with the English and gave refuge to many Tories, but in 1790 their principal chiefs were induced to visit New York and a peace was concluded with the new United States government. After 1763 some Indians of the confederacy, including the major part of the Alabama and Koasati, began to move into Louisiana, and some passed on into Texas where the Alabama later obtained a reservation and still live.

Earlier friendship with the British and the influence of Tecumseh caused a large section of the Creeks, mainly those living on the Tallapoosa River, to rise against the whites after the beginning of the War of 1812. On Aug. 30, 1813, Fort Mims was captured by Creek Indians and

its garrison massacred. In the Creek War which followed, Andrew Jackson defeated the main forces of the hostile Indians in battles at Talladega and Horseshoe Bend, Ala. He was assisted by the Lower Creeks, and in the last and most sanguinary encounter of March 27, 1814, at Horseshoe Bend, by the Cherokee. Over 2,000 warriors were killed in this war, their lands ravaged, and many of their towns burned. The head towns and official governing bodies of the nation, however, did not take part in the hostilities.

As a result of this war the Creeks were compelled to cede a large part of their territory, and pressure by the Georgians for their removal was vastly increased. A section of the nation headed by William McIntosh, who claimed that his town Coweta had a paramount position in the confederacy, signed a treaty at Indian Springs, Ga., on Feb. 12, 1825, ceding all Creek lands in Georgia and part of those in Alabama to the federal government. For this act, regarded as treason to the nation as a whole, McIntosh was killed by a body of Indians from the Upper towns. By another treaty, signed Jan. 24, 1826, the Treaty of Indian Springs was declared null and void, but a portion of the Creek lands was ceded to the government, and the remainder was ceded in 1827 and 1832.

Advance groups of Creeks which had already moved across the Mississippi were joined at intervals by others until about 1840 when nearly all had reached the new land granted to them in the northeastern part of Indian Territory, the present Oklahoma. For some years animosities stemming from the Creek War kept the Lower and Upper towns in a state of semihostility, but in course of time a common government was established modeled on that of the United States, with head and second chiefs and two representative bodies.

The most influential chief during this period and one of the greatest of American Indians was Opothleyaholo or Hupuehelth Yahólo of the Upper Creeks, who, when the Civil War broke out, tried to prevent his people from signing a treaty with the Southern Confederacy. Failing in this attempt, he withdrew from the council and was followed by one third of the nation. These Indians were attacked and severely defeated by the Confederate faction, but Opothleyaholo fought his way north to Kansas and settled near the town of Le Roy where he died. After a series of treaties and negotiations the little Creek Republic came to an end and was incorporated in the present state of Oklahoma and the American Union in 1907.

JOHN R. SWANTON.

CREEL, krēl, George, American publicist and author: b. Lafayette County, Mo., Dec. 1, 1876; d. San Francisco, Calif., Oct. 2, 1953. After working briefly for several midwestern newspapers, Creel in 1898 joined the staff of the *New York Journal*. In 1900 he returned to

Kansas City, Mo., as co-founder of the *Kansas City Independent*, with which he at once began an intensive crusade for clean government. Later he worked on the *Denver Post* and the *Rocky Mountain News*, also in Denver, Colo.

When President Woodrow Wilson created the Committee on Public Information in 1917, he named Creel as its civilian chairman. The committee promoted voluntary censorship, curbed anti-German hysteria, and directed public opinion in a well-integrated propaganda campaign.

In 1933, Creel was appointed chairman of the San Francisco Regional Labor Board. Two years later he was named chairman of the national advisory committee to the Works Progress Administration (WPA). In 1939, President Franklin D. Roosevelt appointed him United States commissioner to the San Francisco International Exposition.

CREEPER, a name applied to various small, oscine birds that creep along the trunks or branches of trees, or over rocks and walls in search of small insects and other food. The true creepers, comprising the family Certhiidae, have tail feathers which are stiffened at their tips and aid them in hitching up the trunks of trees. The birds then flutter down to the base of another tree to repeat the process. The several species of true creepers are found in Europe, Asia, and North America; other creepers are found in Africa and Australia, but they do not seem to be closely related to the true creepers.

The brown creeper (*Certhia familiaris*) of North America is about five inches long and in color and pattern closely resembles the bark of trees. The wall creeper (*Tichodroma*) of the Alps and the mountains of Asia is similar to the nuthatches in the pattern and texture of its plumage, including a soft tail. It is generally considered to be a link between the nuthatches and the true creepers.

CREIGHTON, kri't'n, Mandell, English historian and clergyman: b. Carlisle, England, July 5, 1843; d. Fulham, London, Jan. 14, 1901. He was educated at Merton College, Oxford, was ordained in 1870, and took priest's orders in 1873. From 1875 to 1884 he served as vicar of Embleton, Northumberland, and in the latter year was chosen Dixie professor of ecclesiastical history at Cambridge, being the first occupant of the chair. In 1885 he became canon residentiary of Worcester Cathedral, but in 1891, on his appointment as bishop of Peterborough, vacated both that post and his professorship. In 1897, Creighton was appointed bishop of London, and in this office laid renewed emphasis on ecclesiastical pomp and ritual.

The most important of his numerous historical works is the *History of the Papacy During the Period of the Reformation*, 5 vols. (1882-1894). Other publications of his include *Primer of Roman History* (1875); *Life of Simon de Montfort* (1876); *The Age of Elizabeth* (1876); *Cardinal Wolsey* (1888); *The Early Renaissance in England* (1895); *The English National Character* (1896); *Story of Some English Shires* (1897); *Historical Essays and Reviews* (1902). He was a founder of the *English Historical Review* (1886), and edited it to 1891.

CREIGHTON UNIVERSITY, a Roman Catholic coeducational institution, Omaha, Nebr..

which opened in 1878 and was chartered in 1879. It is named for Edward Creighton, in whose memory his widow endowed the university. There are two undergraduate colleges, Creighton College of Liberal Arts (for men) and University College (for women); a graduate school; colleges of pharmacy and commerce; and schools of law, medicine, nursing, dentistry, and journalism. The average enrollment is 2,400 students.

CRELL, Nikolaus. See KRELL, NIKOLAUS

CREMA, krà'mà, commune, Italy, situated in Lombardy, in Cremona Province, on the Serio River, 23 miles northwest of Cremona. It serves as a market for the rice, livestock, and raw silk produced nearby, and has establishments manufacturing agricultural machinery, textiles, hats, organs, and soap. The seat of a bishopric, it has a cathedral built in 1284-1341 with a Lombard Gothic façade; 16th century palaces; and a number of fine churches, including Santa Maria della Croce, erected in the style of Bramante in 1493-1500. Pop. (1951) 27,936.

CREMATION, the practice of disposing of the dead by burning. The ashes may be buried, cast ceremonially into a river, given mass burial in ossuaries or in individual urns, or scattered.

Prehistoric and Early Historic Practice.—According to the archaeological evidence as interpreted by the British anthropologist V. Gordon Childe, cremation was practiced by Neolithic societies in the British Isles, Brittany, Switzerland, and central Germany, and perhaps in Greece, Syria, and Palestine. Cremation became the preferred method in Britain and northern and central Europe in the Middle to Late Bronze Age (from 1400 B.C.), and in Spain and upper Italy by the Early Iron Age (from 1000 B.C.). It was practiced also at Troy on the Dardanelles, Carchemish on the Euphrates, and occasionally in Crete and Greece, between 1400 and 1000 B.C. In the 1st millennium B.C., both cremation and inhumation (interment) were practiced in most Greek and Italic cities. In western Europe the Celts generally inhumed, while the Teutons in the north still cremated. Since the earliest Phoenician (Semitic) colonists at Motya in Sicily practiced only cremation, it cannot be regarded as an "Aryan" rite. Cremation was never popular in Asia, except in India among the Hindus.

In the Roman Empire cremation at first spread without superseding inhumation, but after 200 A.D. the popularity of cremation tended to decrease even in the European provinces of the empire. Christianity adopted the rite of inhumation practiced in contemporary Palestine by the Hebrews and was influential in diffusing the rite in the empire when the new creed spread there. Cremation remained the favorite rite among Slavonic peoples and the Scandinavian Teutons until their conversion.

On the whole, it may be said that the origin of cremation cannot be connected exclusively with any particular race or people or with a particular level of cultural development. The assertion sometimes put forth that cremation was brought to the Mediterranean region from the East (about 2500-2000 B.C.) seems to be without archaeological or ethnological foundation.

The archaeological evidence also indicates that cremation graves are on the whole no less richly furnished than inhumations. For example, the

richest Bronze Age graves in Britain contain cremated bones, and so do the richest graves in the Early Iron Age cemetery of Hallstatt in Austria. This disproves the notion that the annihilation of the physical remains of the departed was inspired by a more spiritual conception of the soul. It would appear, rather, that animistic beliefs in the survival of the soul and its continued need of physical artifacts after death were compatible with either cremation or inhumation. Only where religious beliefs associated the state of the body with the welfare of the soul, as in the Christian doctrine of the body's redemption and resurrection, was the preservation and conservation of the body a matter of serious concern.

Cremation Among Primitive Peoples.—In primitive cultures which have survived into modern times cremation is widely practiced. Burning is not only supposed to destroy the dead body most effectively and thus to prevent the possible return of the ghost, but since fire serves also as a purifying agency, it is often considered a good means of warding off evil spirits. It must not be supposed, however, that the motives for the prevalence of cremation have been the same in all cases. Besides discouraging the ghost from haunting the corpse and its former abode, and serving as a means of purification from evil spirits and the contamination associated with the dead body, cremation has also, in some instances, as among the Hindus and Chukchi of Siberia, been associated with a belief in a heavenly abode for the spirit of the deceased. The flames of the funeral pyre, leaping upward, are thought to facilitate the ascent of the soul.

While cremation may be the preferred method of disposal of the dead among primitive peoples, lack of fuel often leads to the utilization of other methods. For example, the Chukchi often resort to exposure of the dead, while the Koryak, living farther to the south, adopt cremation when practicable, but throw their dead into the sea from a steep rock when there is a dearth of fuel.

Among the North American Indians we find a great diversity of methods for disposing of the dead. Cremation, when practiced, tended to be limited to special classes of individuals. Among the Miami, for example, victims of witchcraft were cremated. Among the Potawatomi and Ottawa only members of the Rabbit or Great Hare gens burned their dead. The Ojibway burned the bodies of warriors slain in battle. The Menomini burned the corpses of persons dying of scrofula or kindred diseases in order to consume the worms supposed to have caused the disease. If a Choctaw died away from home and it was impracticable to bring the body back, the ashes or bones of the dead were returned instead.

Among South American Indians, cremation is not widespread and occurs primarily north of the Amazon, in the Guianas and Colombia. Some tribes, such as the Aparai, cremate only chiefs and medicine men. Others, notably the Roamaina, cremated the men only, by setting their houses afire, and buried their ashes in an urn.

Cremation in Modern Cultures.—In modern civilizations cremation is practiced largely for hygienic reasons and because of lack of space owing to the great increase of population, especially in the cities. Since the Christian Church, especially in its Roman Catholic and Greek Orthodox forms, has been opposed on principle to cremation, it was not until the latter part of the 19th and the early 20th centuries that the

practice was legalized in European countries and North America. The Cremation Act of 1902 first made statutory provision for cremation in Great Britain, although it was lawful to practice it as early as 1884-1885.

Cremation is now permitted either by law or by custom among about three fourths of the inhabitants of the world. Modern India (Hindu), Japan, Korea, and Indochina (Buddhist) tend to practice cremation. The Protestant countries of western Europe as well as the United States, Canada, and Australia have a considerable number of crematoria regulated by law. In some instances, as in Australia, cremations average as high as 23 per cent of deaths. Cremation in the Western World is usually associated with urn burial of the ashes. In parts of the Eastern World, as in India, the ashes are cast ceremonially into a river. See also DEATH CUSTOMS AND RITES.

DAVID BIDNEY,
Associate Professor of Anthropology and Philosophy, Indiana University.

CREMAZIE, krâ-mâ-zê', (Joseph) Octave, French-Canadian poet: b. Quebec, Lower Canada, Nov. 8, 1822; d. Le Havre, France, Jan. 16, 1879. He was educated at Quebec Seminary, and about 1848 became associated with his brothers in a bookselling business. He contributed a number of poems to the *Journal de Québec*, the best known being *Le vieux soldat canadien* (1855), and his shop became a meeting place for young French-Canadian writers. In 1862 financial reverses forced him to seek refuge in France, where he spent the rest of his life under an assumed name. Crémazie has been called "the father of French-Canadian poetry." In 1883 his friends published his *Oeuvres complètes*.

CREMER, krê-mêr, Sir William Randal, English pacifist: b. Fareham, Wiltshire, England, March 18, 1838; d. London, July 22, 1908. Apprenticed to a carpenter at the age of 15, he was a founder of the Amalgamated Society of Carpenters and Joiners (1860). He became an ardent advocate of world peace, and served as secretary of the Workmen's Peace Association from 1871 to 1908, edited the *Arbitrator* from 1889, and did much to further international arbitration. He was also secretary of the Inter-parliamentary Union from 1889. He served in Parliament from 1885 to 1895 and from 1900 until his death. He was awarded the Nobel Peace Prize for 1903, and gave £7,000 of the £8,000 he received to the International Arbitration League. He was knighted in 1907.

CREMIEUX, krâ-myú', Adolphe (real name ISAAC MOÏSE CRÉMIEUX), French lawyer and politician: b. Nîmes, France, April 30, 1796; d. Paris, Feb. 10, 1880. He practiced law in Nîmes and, from 1830, in Paris. Elected to the Chamber of Deputies in 1842, he served until 1848, when he became minister of justice in the provisional government set up after the overthrow of Louis Philippe. Re-elected a deputy in 1849, he was

among those imprisoned after Louis Napoleon's coup d'état in 1851. After his release he confined his activities to the practice of law until 1869, when he again became a deputy. As minister of justice in 1870-1871, Crémieux was responsible for a decree enfranchising the Jews of Algeria, and for the abolition of the death penalty for political offenders. In 1875 he was appointed senator for life.

CREMONA, krâ-mō'nâ, Luigi, Italian mathematician: b. Pavia, Italy, Dec. 1, 1830; d. Rome, June 10, 1903. Educated at the University of Pavia, he became professor of higher geometry at the University of Bologna in 1860. He taught in Milan from 1866 to 1873, when he went to Rome, where he became director of the engineering college. He served as a senator from 1879 and was minister of education in 1898. He is best known for his work in graphical statics and projective geometry. His works include *Introduzione ad una teoria geometrica delle curve piane* (1862) and *Elementi di calcolo grafico* (1879).

CREMONA, krê-mō'nâ (Ital. krâ-mō'na), the name of a province and a commune in Italy.

(1) The province, situated in Lombardy, has an area of 678 square miles; it includes a fertile plain which yields cereals, flax, and forage. Silk culture and the dairy industry are of special economic importance. Pop. (1951) 382,673.

(2) The commune, capital of the province, is situated on the left bank of the Po River, 49 miles east-southeast of Milan. It is an active agricultural center, with meat and dairy industries. Two specialties, *torrone* (hard candy) and a sort of French mustard, are widely exported. Other products include silk textiles, hats, pottery, and firearms. A traditional occupation is the making of violins, for which the city has been famous for centuries: its celebrated school of violin makers, which included the Amati, Stradivari, and Guarneri families, attained its highest development from the 16th to the 18th centuries, and the instruments made then are still the most highly valued in the world.

Cremona is also of unusual architectural interest. The main square is surrounded by beautiful medieval buildings, including the cathedral, begun in the 12th century, with an impressive marble façade and rose window and a richly ornamented interior; the Torrazzo, or clock tower, 360 feet high, built about 1250-1284; the octagonal baptistery, erected in 1167, one of the finest of its kind; and the Palazzo Comunale and the Loggia dei Militi, both of the 13th century. There are also several other fine churches and palaces. The Renaissance Church of San Sigismondo has an imposing cupola, and the Church of Santa Margherita contains frescoes by Giulio Campi, founder of the local school of painting which flourished in the 16th century. Many of the school's works are in the municipal museum. There are various schools, a fine library, and a large theater.

History.—Cremona was founded by the Romans in 218 B.C. as a colony, and was fortified to withstand the Carthaginian invasion and as a base for the conquest of Cisalpine Gaul; it was plundered and burned in 69 A.D., but was later rebuilt. In 602 it was taken by the Lombards; soon the local bishops gained privileges and extended their influence over the surrounding

countryside. The commune, formed in the 11th century, included nearby Crema, which soon rebelled with Milan's aid. Cremona sided with the imperial cities, and suffered from fierce internal struggles between Guelphs and Ghibellines until in 1344 it fell to the Visconti of Milan. Thereafter it followed Milan's fortunes, and in the wars between France and Spain for the domination of Lombardy it changed hands several times. Pop. (1951) 69,100.

CREODONTA, krē-ō-dōn'ta, an extinct suborder of the Carnivora (q.v.), distinguished by many primitive characters, and especially by the fact that the scaphoid and lunar bones of the wrist are separate instead of united into a single bone as in modern Carnivora. In all modern land carnivores the last premolar tooth in the upper jaw and first true molar in the lower jaw are enlarged and peculiarly adapted to cutting flesh (hence called "carnassials"), working against each other like a pair of shears. This is also the case with one group of the Creodonta, from which the modern Carnivora are descended. But in most creodonts there is no specialized carnassial, or it is developed from other teeth; these groups evolved on lines similar to the true Carnivora, but have left no descendants. One group, the arctocyonids, resembled the bears, with omnivorous teeth, plantigrade feet, and large compressed claws. Another group (*Mesonyx*, *Pachyaena*, etc.) resembled rather the hyenas, with large strong teeth fitted for bone crushing and digitigrade feet. Others had the teeth more especially adapted to cutting flesh, the first upper and second lower molar being developed into carnassials in *Oxyacna* and *Patriofelis*, the second upper and third lower molar in *Hyacnodon*. Besides these larger forms, from the size of a polar bear to that of a prairie wolf, there was a great variety of smaller creodonts, some more or less transitional to the primates, others to the insectivores. The early creodonts appear to represent most nearly the central stock from which most, if not all, of the modern mammals are descended (see CONDYLARTHRA). Creodonts were the dominant Carnivora of the Eocene epoch, and a few survived into the Oligocene, when their place was taken by the true Carnivora of more modern type. The evolution in the creodonts and true carnivores of carnassials of remarkably similar form, out of different pairs of teeth originally much less alike, is an excellent instance of "convergence" in evolution.

CREOLE, krē'ōl, a person born in America or the West Indies Islands, of pure European blood; as a Spanish creole. The term is sometimes applied, but wrongly, to any person born within tropical latitudes, of whatsoever color. In South and Central America the creoles enjoy high social privileges, and a creole nobility long existed in Venezuela. They are sallow, finely formed, and dark-eyed. Creole dialects are an interesting example of broken-down grammar. By English writers creole has sometimes been used to mean a mestizo or mulatto; but it cannot properly be applied to any person of mixed race, non-Latin stock or of European birth.

Consult Thomas, *Theory and Practice of Creole Grammar* (1869).

CREOLE CASE, 1841-1842, one of the landmarks of the antislavery struggle. On Oct. 27,

1841 the brig *Creole* sailed from Hampton Roads to New Orleans with 130 slaves; on November 17, 17 of them rose and overpowered the crew, killed one of the owners, and ran the vessel into the English port of Nassau. The authorities, as they were wont, imprisoned those directly charged with mutiny and murder, and let the rest go. Webster, then secretary of state, demanded from England the surrender of the whole, as being legal property of a state under the Constitution, on a legal voyage (Coastwise Slave-Trade Act of March 2, 1807), and covered by the United States flag on the high seas. This was exactly Calhoun's theory. The English government refused, but a new extradition treaty was agreed on (Aug. 9, 1842). In the House, March 21, 1842, Joshua R. Giddings presented a set of resolutions which formulated the position of the political antisavery party. The resolutions declared that the states have exclusive jurisdiction over slavery in their own territory; that the federal government has exclusive jurisdiction over the high seas, that slavery, as an abridgment of the natural rights of man, can exist only by edict of a municipality and within its power of enforcement (this was Judge Curtis's argument in the *Dred Scott* case); that a vessel on the high seas has passed from municipal to national jurisdiction, so that Virginia law ceased to apply to the *Creole* when it left Virginia territory; that the Negroes in resuming their natural rights violated no federal law, and *ex hypothesi* no state law; and that attempts to re-enslave them were violations of the Constitution and laws, the rights of the free states and national honor. The resolutions roused a storm. John Minor Botts (q.v.) of Virginia moved a counter resolution that no good citizen, and especially no national representative, should provoke contention over a question on which diplomatic negotiations were pending, and which might plunge the whole civilized world into war; and that Giddings' resolutions justified mutiny and murder. He asked a suspension of the rules to give his resolution precedence of Giddings', whose colleague moved the previous question; and after a two days' wrangle on points of order the resolution was passed without debate, 125 to 69. Giddings at once resigned; his constituency immediately re-elected him by an overwhelming majority, and instructed him to push his resolutions to a vote. As this would embarrass the Democratic Party—the first two clauses being their pet tenets, and the others only obvious inferences from them—they evaded it by abolishing "resolution day" for the rest of the session, devoting the day to other business when it came around. Giddings' resolutions expressed the legal basis of one phase of the antislavery agitation. The controversy with England over the case dragged on for more than a decade. It was finally settled in 1853 when an Anglo-American commission awarded an indemnity of \$110,330 to the United States.

Consult Giddings, J. R., *History of the Rebellion* (New York 1861).

CREOLE STATE, Louisiana, where the direct descendants of the original French and Spanish colonists form an important element in the social fabric.

CREOLIN, a mixture of cresols and creosols and other allied substances derived from

the destructive distillation of wood, once used very widely in watery emulsion as an antiseptic.

CREON, krě'ōn, the name of two rulers in Greek legend: (1) a Corinthian king, who plays a minor part in the myth of Jason and Medea (qq.v.); (2) a Theban king, brother of Jocasta, the wife of Laius and mother of Oedipus. After Oedipus had unwittingly slain his father, King Laius, Creon ruled Thebes and offered Jocasta and the crown to whoever would free the city from the Sphinx. Oedipus slew the monster, married Jocasta (not knowing she was his mother), and became king. After the deaths of Eteocles and Polynices (q.v.), Oedipus' sons and successors, Creon resumed the throne. See also **ANTI-GONE**; **OEDIPUS REX**.

CREOSOTE, krě'ō-sōt, a term derived from two Greek words meaning "meat" and "to preserve," is applied to products of both wood tar and coal tar. By far the larger amount of all creosote is derived from coal tar. Wood creosote, or creosote from wood tar, is commercially a medicinal whose major components are the phenolic derivatives guaiacol and cresol. It is described as a colorless or slightly yellow oil, highly refractive, with a characteristic smoky odor, and a caustic, burning taste. Materials of this nature are present in smoke from hardwoods, and thus serve to preserve meat and to impart desired flavors at the same time.

Creosote from coal tar is more accurately called creosote oil and comprises materials boiling above 235°C. The second fraction from coal tar distillation is carbolic oil, often called insecticide oil. Removal of insecticide oil from creosote oil is rarely complete. Distillation of tar is continued until a pitch with the desired melting point is reached; this pitch is used as road and roofing tar. Distillation of creosote usually ends between 400°C. and 450°C. The commercial product, whose chief use is that of wood preservation, contains over 160 identifiable chemical compounds, mainly aromatic hydrocarbons with smaller quantities of phenolic and nitrogen bases. Some 25 to 30 compounds account for over one half the composition of commercial creosote.

Creosote is made to penetrate deeply into railroad ties, telephone poles, and marine piling by placing the material to be treated in giant closed vessels, from which air and moisture are removed, and into which creosote is admitted under heavy pressure and at high temperatures. Tests show that creosote-treated wood remains sound and serviceable even after exposure to very severe conditions for 30 years or longer.

W. T. READ.

CRERAR, krě'rär, **Henry Duncan Graham**, Canadian soldier: b. Hamilton, Ontario, Canada, April 28, 1888. He was educated at Upper Canada College, Toronto, the Royal Military College, Kingston, the Royal Staff College, Camberley, England, and the Imperial Defense College, London. He served in World War I, rising to the rank of staff officer in the Canadian Corps in 1918, and became general staff officer at the War Office in 1925. In 1940-1941, during World War II, he was major general and chief of the Canadian general staff; in 1944 he was made general, and in 1944-1945 commanded the 1st Canadian Army. He retired in 1946, but in 1947

headed a Canadian mission to Japan and in 1948 was the first Canadian to be appointed aide-de-camp to the king.

CRERAR, **John**, American financier and philanthropist: b. New York, N. Y., March 8, 1827; d. Chicago, Ill., Oct. 19, 1889. He accumulated a fortune in the manufacture of railroad supplies, became a director of several railroads, and was one of the incorporators of the Pullman Palace Car Company. He left \$2,500,000 to found the John Crerar Library in Chicago, stipulating that it should exclude "all skeptical trash and works of questionable moral tone." His will also provided \$100,000 for a statue of Lincoln by Augustus Saint-Gaudens in Lincoln Park, Chicago, and \$1,000,000 for charitable and religious organizations.

CRERAR, **Thomas Alexander**, Canadian statesman: b. Molesworth, Ontario, Canada, June 17, 1876. He was educated at Portage la Prairie, helped on his father's farm until the age of 19, and then taught school for five years; later he attended Manitoba College and farmed for several years. He organized the Grain-Growers' Grain Company (later United Grain Growers, l.t.d.) formed to give farmers better selling facilities on the Winnipeg exchange, and was its president, 1907-1929. He was minister of agriculture under Sir Robert Borden, 1917-1919, directing food production and control during World War I. He was leader of the National Progressive Party, 1921-1922; minister of railways and canals, 1929-1930; and minister of mines and resources, 1935-1945, when he became a senator.

CRES, tsrěs (Ital. **CHERSO**, kěr'sō), island, part of Croatia, Yugoslavia, located at the head of the Adriatic Sea, northwest of Croatia. It is about 40 miles long, with an area of 158 square miles. Its leading occupations are sheep raising, agriculture, and fishing. It passed from Austria to Italy in 1919 and to Yugoslavia in 1947. Pop. of Cres district (1948) 3,393.

CRESAP, krě'săp, **Michael**, American trader and Indian fighter: b. Allegany County, Md., June 29, 1742; d. New York, N. Y., Oct. 18, 1775. The son of a Yorkshireman who had settled in western Maryland, Cresap married while yet a minor, became a merchant, and established a settlement on the Ohio River below Wheeling, W. Va. In the spring of 1774 he defeated a party of Indians in a skirmish sometimes called Cresap's War which precipitated Lord Dunmore's War (see **COLONIAL WARS IN AMERICA**). A party of whites had treacherously massacred the family of Chief Tah-gah-jute, or Logan (q.v.) on Yellow Creek, and Cresap, as leader of the white men in that region, was accused of the crime. Reference to the episode in Thomas Jefferson's *Notes on the State of Virginia*, published in 1782, served to attach Cresap's name to the deed, until his son-in-law, Luther Martin, and later Brantz Mayer, showed that he had been in Maryland at the time of the occurrence. The facts have never been made entirely clear. In August 1775, Cresap went with a company of men to Boston and joined Washington's army, but became ill before he took command and died on the way home.

For details consult Jacob, J. J., *A Biographical Sketch of the Life of the Late Capt.*

Michael Cresap (Cumberland, Md., 1826; new ed., with notes, by Brantz Mayer, Cincinnati 1866), and Mayer, Brantz, *Tagah-jute*, or *Logan the Indian and Captain Cresap* (New York 1867).

CRESCENDO, krě-shě'n'dō, a musical term signifying that the notes of the passage over which it is placed are to be performed with constantly increasing volume of tone. The ancient Romans, as we learn from a passage in Cicero, were aware of its beauty, and practiced it continually. Crescendo passages are usually indicated by the abbreviation *cresc.* or the mark < signifying piano to forte and fortissimo; the corresponding mark > diminuendo, marking the transition from forte to piano.

CRESCENT, krěs'ěnt (Lat. *crescens*, growing), an emblem representing the moon in her state of increase. The Egyptians and the Greeks decorated their moon goddesses, Isis and Io, with the crescent, which announced the returning light of the moon. Athenian citizens of illustrious birth wore crescents of ivory and silver upon their buskins; and the same mark of distinction was granted to the patricians and senators of Rome. It was used by the Romans as an emblem of the eternity of empire. Hence it was found on medals of many cities, particularly of Byzantium, as capital of the Eastern Empire, whence it is supposed to have been borrowed by the Ottomans. Since their establishment in Europe it has been the universal emblem of their empire. It is frequently seen on churches in Russia, generally surmounted by the cross, indicating the Byzantine origin of the Russian Orthodox Church. During the Crusades, particularly, the crescent was the distinguishing symbol of the Moslems, as the cross was representative of the Christians.

The word is also applied to a Turkish musical instrument introduced into the German military bands at the time of the Turkish wars and now in general use in military bands. It consists of a staff surmounted by a cap and supporting several crescent-shaped brass plates on each of which little bells are hung. The instrument is played by being jingled in time to the music.

In heraldry, the crescent is used both as a bearing or charge; and as a difference or mark of cadency. In the latter cases, it designates the second son and those that are descended from him.

CRESCENTIA. See CALABASH-TREE.

CRESCENTINI, krā-shān-tě'ně, **Girolamo**, Italian singer: b. Urbino, Feb. 2, 1766; d. Naples, April 24, 1846. He was styled the Italian Orpheus, because of his exquisite mezzo-soprano. After studying with Gibelli at Bologna, he made his debut at Rome in 1783, and then toured through the principal cities of France, England, and Italy. Napoleon awarded him the Iron Crown in 1805, and was his patron (1806-1812). Leaving Rome in 1816, he became a professor of voice culture at Naples. His treatise on vocalization was published in both French and Italian.

CRESCENTIUS, krě-sě'n'shī-ūs, **Johannes** or **John** (surnamed NOMENTANUS), Roman patriot; d. 998 A.D. One of a family of noble

Romans, he was a leader of the party in Rome opposed to the rule of the Holy Roman emperor in the 10th century. From 985 to 996 his rule in Rome was practically undisputed, and he was recognized as Patricius by the Byzantine empress.

In 996 Otto III came to Rome, and overthrew the rule of Crescentius temporarily, but the latter resumed his position when the emperor left the city, drove the pope, Gregory V, from Rome, and supported the antipope, John XVI. Otto, however, finally defeated Crescentius in 998 at the castle of Sant' Angelo and had him beheaded.

CRESCENZI, krā-shě'n'tsě, **Pietro**, or **PETRUS DE CRESCENTIIIS**, Italian writer on agriculture: b. Bologna c.1230; d. about 1310. At the age of 70 he was made senator, and he then carried into execution his principles of agriculture on an estate near Bologna, in the cultivation of which he passed the remainder of his life. He has left a work on agriculture entitled *Opus Ruralium Commodorum*, a remarkable monument of his time, of which it is far in advance. This work was written originally in Latin. There exists an Italian translation (1478), esteemed very highly on account of the purity of the language, which has given rise to the opinion that Crescenzi wrote in his native tongue. His principles are simple, founded upon experience and free from many prejudices which continued to prevail in Europe for centuries after. His work was translated into several European languages, particularly for Charles V of France, in a splendid manuscript (1373), still extant; and no sooner was the art of printing invented than copies of this work were greatly multiplied. The oldest known edition, now very rare, appeared at Augsburg in 1471. The genus *Crescentia* was named by Carolus Linnaeus in honor of the famous author, who was probably the first since the days of the Romans to point out the high value of agricultural science.

CRESCIMBENI, krā-shēm-bā'ně, **Giovanni Maria**, Italian scholar and poet: b. Macerata, Oct. 9, 1663; d. Rome, March 8, 1728. He was one of the 14 poets associated with Christine of Sweden in founding the Academy of Arcadians in Rome, of which he was the first president (1690-1728). In 1698 appeared his *Istoria della volgar poesia*, a work of vast industry, but destitute of method and criticism. He next published his *La bellezza della volgar poesia* (1700), which passed in a short time through three editions, and like the earlier work was first made capable of being understood and enjoyed by the *Comentarij intorno alla storia della volgar poesia* (1702-1711).

CRESCO, krěs'kō, city, Iowa, and Howard County seat; altitude 1,300 feet, 18 miles west-northwest of Decorah, and served by the Chicago, Milwaukee, St. Paul and Pacific Railroad. It is a shipping point for livestock, eggs, butter, and poultry. There are two large creameries, bottling works, and manufactures of wooden products and barn cupolas. New varieties of popcorn have been developed nearby. A few miles away is Niagara Cavern with a 60-foot waterfall. The city is governed by a mayor and council and owns its waterworks. Pop. (1950) 3,638.

CRESOL, krě'söl, an aromatic hydrocarbon (q.v.) having the formula $\text{CH}_3\text{C}_6\text{H}_4\text{OH}$, which may be regarded as derived from phenol by the substitution of methyl (CH_3) for one of the hydrogen atoms in the benzene nucleus. Like all disubstitution benzene compounds, cresol exists in three isomeric modifications, known respectively as orthocresol, metacresol, and paracresol. All three occur in coal tar, though the ortho- and para-compounds are present in much larger quantity than the meta-compounds. The ortho- and meta-compounds readily yield nitro-derivatives, and are used in the manufacture of disinfectant, insecticide, photo developer, explosives, and paint remover.

Orthocresol melts at 30.4°C . and boils at 370°C .; metacresol melts at 10.9°C . and boils at 202°C .; and paracresol melts at 36°C . and boils at 202°C .

CRESPI, kräs'pě, **Giuseppe Maria**, Italian painter, known as LO SPAGNUOLO: b. Bologna March 16, 1665; d. there, July 16, 1747. He particularly resembles Rembrandt in his depiction of light and shade. His most famous picture is *The Massacre of the Innocents*. He painted for Cardinal Ottoboni *The Seven Sacraments*, now in the Dresden gallery. When his patron, Cardinal Prospero Lambertini, became Pope Benedict XIV, he conferred the honor of knighthood on him.

CRESPI, kräs'pě, **Juan**, Spanish missionary and explorer: b. Spain 1721; d. Carmel Mission, Calif., Jan. 1, 1782. A pupil and close friend of Junipero Serra, he came to America in 1749 and became a member of the Franciscan College of San Fernando, Mexico. With the expulsion of the Jesuits from Lower California in 1767, he was put in charge of a mission there, and two years later he was one of the first of a band of explorers and missionaries to claim San Diego for Spain. He pushed further north with Gaspar de Portolá and was one of the discoverers of San Francisco Bay. He returned to San Diego and became one of the founders of the Carmel Mission there, returning to San Francisco Bay in 1772 to explore the route around it. In 1774 he was one of a band to make a sea voyage to Alaska and back. An extensively traveled and learned man, his diaries were translated and edited by Herbert E. Bolton in *Juan Crespi, Missionary Explorer on the Pacific Coast, 1769-1774* (Berkeley, Calif. 1927).

CRESS, krěs, various plants of the family Cruciferae. The cultivated ones are all used as salads, for which their pungent foliage especially recommends them. The common or garden cress or peppergrass (*Lepidium sativum*) is generally found in gardens as a spring annual. The seeds may be sown as soon as the soil can be worked and the fresh herbage cut for use in about three weeks. Successive sowings should be made every three or four days. The plant resembles watercress in flavor, and makes an excellent garnish. Virginia cress (*L. virginicum*) is a similar species and has been grown and used like the preceding. Winter or upland cress (*Barbarea vulgaris*) is an annual, common in fields in Europe and America and sometimes cultivated for winter use, as is also its close relative (*B. bracteata*) which is called early winter or Bell Isle cress. Watercress (*Radic-*

ula nasturtium-aquaticum) is a perennial aquatic herb common in cool brooks and yielding an important winter salad where the streams do not freeze. Though it does best in gravelly bottomed shallow streams, it may be cultivated in any moist ground, or under greenhouse benches if well supplied with water. Indian cress, which is a species of *Tropaeolum*, is commonly known as nasturtium, a popular garden flower whose foliage, flower buds, and blossoms are used in England as salads, and its immature fruits as a substitute for capers.

CRESSET, krěs'ět. (1) A bowl-shaped article made of incombustible material, used to contain a light, and hung from above or suspended on a pole or placed as beacon on a watch tower or other prominent place. The cresset light was formerly the flame from a coil of pitched rope, but in more modern times oil and wick were used. The large lantern of ancient days when suspended from the end of a long pole and carried on a man's shoulder was called a cresset. A stone containing bowl-shaped hollows which are sometimes used as cressets is called a cresset stone. (2) An iron fire cage placed inside casks to make them bulge, used by coopers, who made barrels by hand.

CRESSIDA, krěs'i-dā, in Greek legend a daughter of Calchas, the Trojan priest, whose fame rests upon the story of her amour with Troilus, a valiant Trojan warrior, and her eventual deserting of him for Diomedes, a Greek soldier. The original story of Troilus and Cressida started as far back as Homer, who knew her as Briseis, and culminates in the epic poem, *Troilus and Criseyde* (q.v.), by Geoffrey Chaucer. Other interpreters of the romance were Dictys Cretensis, Giovanni Boccaccio, and Guido delle Colonne.

CRESSOL. See CRESOL.

CRESSON, krěs'n, **Elliott**, American philanthropist: b. Philadelphia, March 2, 1796; d. Feb. 20, 1854. He was a prosperous merchant in Philadelphia, where he resided all his life, and a member of the Society of Friends. He helped to buy land for the first African colony of liberated slaves in the territory of Bassa Cove, Liberia, and was an active leader of the American Colonization Society. He recommended his measures with the eloquence of sincere conviction, and met with much favor and success. He sailed to England in 1840 where he spent some years in advocating the project of colonization. His time and labor were contributed without pay, and by his will he distributed his estate to a great variety of charities.

CRESSON, borough, Pennsylvania, in Cambria County, at an altitude of 2,022 feet, 12 miles west of Altoona, on the Pennsylvania Railroad. It is a summer resort situated in the Allegheny Mountains and is noted for its scenery and magnesia springs. It has large railroad shops and is a shipping point for coal mined in the vicinity. Mt. Aloysius Junior College and the state tuberculosis sanatorium are located here. Pop. (1950) 2,569.

CREST, krěst (Lat. *crista*, plume or comb), the rising on the defensive armor of the head,

also the ornament frequently affixed to the helmet, such as a plume or tuft of feathers or a bunch of horsehair. Warriors have always been in the habit of adorning their persons, and the helmet, from its conspicuousness, was very naturally chosen as the place of one of the principal ornaments. The crests of the earlier Greeks were of horsehair; afterward plumes, especially red ones, were adopted.

In the Middle Ages, when rank and honors became hereditary, and particular heraldic devices were appropriated to particular families, the crest became a distinguishing hereditary mark of honor. It is denoted in heraldry by a figure placed upon a wreath, coronet, or cap of maintenance, above both helmet and shield; as for instance, the crest of a bishop is a miter. The crest is considered a greater criterion of nobility than the armor generally. It is commonly a piece of the arms, rests on a wreath of the principal metal and color of the coat of arms, color and metal alternating, or on a cap of maintenance.

CRESTING, in architecture, is an ornamental finishing in stone, tiles, or metal in the wall or ridge of a building, such as the cresting at Exeter Cathedral, where the ridge is ornamented with a small range of leaden fleurs-de-lis

CRESTON, krēs'tūn, city, Iowa, Union County seat, at an altitude of 1,312 feet, 57 miles southwest of Des Moines, and served by the Chicago, Burlington and Quincy Railroad. It was named for its location on the crest of the ridge between the basins of the Mississippi and the Missouri rivers. The city is the shipping and trading center of Iowa's bluegrass region, which raises corn, oats, hay, potatoes, hogs, and cattle. It was laid out in 1869 for the shops of the new Chicago, Burlington and Quincy Railroad and as divisional headquarters. There are railroad shops and yards, stockyards, creameries, bottling works, and flour mills. The city's water supply is drawn from two large reservoir lakes. Creston was incorporated in 1871 and chartered in 1881. The municipal government is by a mayor and council. Pop. (1950) 9,317.

CRESWICK, krēz'ik, Thomas, English landscape painter: b. Sheffield, Feb. 4, 1811; d. Bayswater, Dec. 28, 1869. He studied drawing at Birmingham under John Vincent Barber and early showed artistic talent. His first pictures were admitted into the Royal Academy exhibition when he was only in his 17th year, and his success was afterward continuous. He was elected an associate of the Academy in 1842 and an academician in 1851. Among his better known works are *England* and *The London Road a Hundred Years Ago*. Tending particularly toward depicting English rivers, Creswick's landscapes are pleasing and attractive, and display much delicate and finished detail. He was a well-known book illustrator and was also known as an etcher. His works were collected for the London International Exhibition of 1873 and a catalogue compiled by T. O. Barlow.

CRETACEOUS, krē-tā'shūs, a name applied by geologists to the latest period of the Mesozoic era, and to the system of rocks then formed. It follows the Jurassic and precedes the Tertiary. The name comes from the Latin for chalk and in the type localities the formation is

usually characterized by white, soft chalk, but sometimes, more especially in Italy and the south of France, this chalk is replaced by compact solid limestones. In England and France the Cretaceous rocks consist chiefly of carbonate of lime, but usually abound with silica in the shape of nodules, plates, and veins, and with iron pyrites in nodules and radiated cylinders. The organic remains in the chalk are, with few exceptions, eminently marine, and from the fine texture of the substance in which they have been embedded are usually well preserved. They embrace seaweeds, sponges, corals, echinoderms, mollusks, crustacea, fishes, and reptiles. Deep-sea dredgings in the Atlantic have revealed the fact that a fine, white organic ooze, resembling the chalk, is still in process of formation in the oceanic abysses at the present day. In America, the system is divided into Lower Cretaceous or Comanchean, and Upper Cretaceous. Some writers give Comanchean the rank of a period, making it coordinate with Jurassic, and restrict the term Cretaceous to the Upper Cretaceous as above defined. During Lower Cretaceous the continent of North America was not very different in outline from now, except that the Gulf of Mexico was expanded, and that the Pacific still covered the site of much of the present Coast Ranges. During Upper Cretaceous time, a great arm of the sea encroached on the land, finally extending from the Gulf of Mexico to the Arctic. In this a great thickness of marine sediments was laid down. At the same time much of the Atlantic and Gulf coastal plain was under water. Toward the close of the period (Laramie epoch) the interior sea again retreated, leaving a large area of low swamp, in which much coal was formed. The period, and the Mesozoic era as well, were brought to a close by folding which produced the Rocky Mountains. The Andes were probably folded at the same time.

Life of the Cretaceous.—The great groups of reptiles which developed during Triassic and Jurassic reached their climax in Cretaceous, and dinosaurs, pterosaurs, mosasaurs, ichthyosaurs, and plesiosaurs all became extinct at the close. The ammonite cephalopods also died out completely. The most notable addition was the development of the modern types of flowering plants, which became dominant before the close of the period.

CRETE, krēt, or **CANDIA** (ancient name Creta; Turkish name KIRID), one of the most important islands belonging to Greece, and the 4th largest island in the Mediterranean, 60 miles from the Peloponnesus and 160 miles from the African coast; it is 160 miles long, 6 to 35 broad, and contains 3,199 square miles. A high chain of mountains covered with forests runs through the entire length of the island, in two ranges. On the northern side it declines moderately to a fertile coast, provided with good harbors; on the south side, steeply to a rocky shore, with a few roadsteads, and reaches its greatest height in the lofty Psiloriti (the ancient Ida), 8,195 feet high, and always covered with snow. Numerous springs give fertility to most of the valleys, in which, and on the declivities of the mountains, is seen a luxurious vegetation. The air is mild; the summer is cooled by the north winds, the winter is distinguished only by showers of rain. Earthquakes, however, are not infrequent. Agriculture is at a very low stage, and education

and the amenities of civilized life are lacking. Olive production is the principal source of wealth. Other products are wheat, oranges, lemons, silk, grapes, wine, valonia, carobs and honey. Silk production has declined. Crete is believed to be rich in minerals (iron, lead, manganese, lignite, sulphur, copper and zinc are found). The inhabitants (estimated at 1,200,000 in ancient times or 900,000 in the time of the Venetians), are now about 386,000. Moslems have mostly emigrated. The capital is Canea. Pop. 26,604. The chief city and center of trade is Candia. Pop. 33,404.

Greek mythology made Crete the scene of many of the adventures of the gods and heroes. Here Saturn is said to have reigned and afterward Minos.

Archæological exploration and excavation in modern times have revealed that a Neolithic period of evolution from about 10,000 to 3315 B.C. was followed by the Minoan or Ægean period of civilization, which existed contemporaneously with the first dynasty of Egypt, from 3315 to 1450 B.C., and reached its culminating point in Crete. Minoan towns and palaces have been uncovered in different parts of the island, which recall the skill attributed to Dædalus (q.v.). They exhibit architecture and engineering of a high order, unsurpassed for domestic conveniences in modern times. At Cnossus in the ruined palace of Minos (q.v., whence Minoan), the thalassocratic king of the eastern Mediterranean, in the Hagia Triada and its shrine near Phæstus, in the palace at Phæstus, in the uncovered ruined towns at Palaikastro, Gourni and Zakro, in the shrine and Dictæan cavern, the legendary birthplace of the Cretan Zeus, near Psychro, and in the ruins on the neighboring islets of Pseira and Mochlos, the finds include archives of clay tablets in great quantities inscribed with the early forms of Minoan pictographic and linear script, polychrome decorated pottery, lifelike ivory and clay figures, mural paintings revealing the customs of the period, enormous decorated storehouse jars, stone and bronze votive figures and objects of cult, sarcophagi, etc. While at Cnossus, also, have been uncarthed the foundations of what are acknowledged to be the traditional labyrinthine prison of the Minotaur (q.v.) or bull of Minos, the incestuous monster for whose gratification Athens was compelled to send an annual tribute of seven noble maidens and seven boys until Theseus (q.v.) killed the beast, probably during an invasion of the island which consummated the catastrophe that overwhelmed this early Cretan culture.

The island figures little in Greek history, and took no part in the wars with the Persians. It possessed a number of independent towns often at war with each other, but ready to combine against a stranger. Crete was conquered by the Romans 67 B.C. In the year 823 it passed from the Roman emperors of the East to the Saracens, who built the capital, Candia, on the ruins of Heraclea, but were expelled again in 961 by the Greeks. The Byzantine sovereign sold the island to the Venetians in 1204, who fortified most of the cities, won the good will of their new subjects by a mild government, and repelled all the assaults of the Genoese and Turks till the middle of the 17th century. About this time the attacks of the Turks became more

determined. They landed a large force in 1645, which soon took Canea and Retimo, and besieged the capital with vigor. The siege, the longest in modern history, lasted over 20 years. To assist the Venetians volunteers from all parts of Europe poured in. The Christians, after having exhausted all means of defense, were compelled to surrender to the Turks Sept. 27, 1669. At the time of the capitulation the garrison consisted of only 2,500 soldiers; 30,985 Christians and 118,754 Turks were killed or wounded during the siege. Having obtained possession of the capital, the Turks now endeavored to expel the Venetians from the strongholds which remained to them on the island and before the expiration of the 17th century they had been successful in their efforts.

Three pashas, at Candia, Canea and Retimo, now governed the island. On account of the feuds of these pashas the inhabitants of the western mountains succeeded in forming a government of their own, under Turkish protection. As the compacts made with them by the Turks were not always observed, they were wont in such cases to take up arms, and though they were often defeated they were never entirely subdued. The pashas having demanded hostages of them in 1821, they joined the Greek insurgents.

Had the mountaineers been armed when the Turks made their first descent on the island, it would probably have been impossible for the invaders to have maintained themselves in Candia, but as it was the island remained under Turkish rule. In 1868 a formidable insurrection, fomented by Greece, was with difficulty suppressed by the Turks, after a tedious conflict. In consequence of this revolt the Turks granted to the Cretans a certain degree of autonomy, but Turkish bad faith produced another revolt nine years later. At that time a new constitution of a parliamentary character was inaugurated, but many of its provisions were annulled in 1889. In 1896 there was again a rising against the Turks, in which, as before, the Greeks took part, one result being the outbreak of war between Greece and Turkey. The Greek troops landed on the island were withdrawn at the instance of the Great Powers, who undertook to secure an autonomous government under Turkish suzerainty and to cause the Turkish troops to be withdrawn. On Sept. 6, 1898 the Mohammedans of Candia rose against the Christians, and the fighting resulted in the death of many of the latter, including some British sailors. The leading powers at once demanded the complete withdrawal of the Turkish troops who had abetted the rebels, and ultimately, on October 11, the Sultan complied with their demand, the troops being soon after withdrawn. Shortly afterward Prince George of Greece was appointed high commissioner or governor of the island. A national assembly met and formed a constitution providing for the creation of a legislature and guaranteeing freedom of religion to all inhabitants. Although order was restored, popular sentiment continued to be increasingly in favor of annexation to Greece, and in 1904 the High Commissioner attempted to gain the consent of the Powers to such a step but without success. There were revolts against the high commissioner's arbitrary policy in 1904 and 1905; in the latter year a revolutionary assembly proclaimed the union

of the island with Greece, and this was followed by a similar proclamation on the part of the regular Chamber. The powers intervened, and after some desultory fighting the insurgents laid down their arms in November 1905. In 1906 Prince George resigned the high commissioner-ship of Crete. The overwhelming majority of Greeks in the Cretan Assembly persisted in treating their island as an integral part of the Greek kingdom, while the government at Athens was obliged to respect Crete as a shadowy vassal of Turkey. It was a Cretan leader, Eleutherios Venizelos, who in 1910 became premier of Greece and organized the Balkan League that prepared to wage war against Turkey. A popular uprising in March 1912 put an end to the government that had been forced upon the island by the protecting powers, and erected in its stead a provisional government, the reception of whose delegates at Athens in October 1912 was one of the excuses for the outbreak of the Balkan War. By the Treaty of London (May 31, 1913) Turkey renounced all sovereignty over the island. The union of Crete with Greece was formally recognized by the other Balkan states by the Treaty of Bucharest (Aug. 10, 1913). In 1941 when Britain decided to send part of her army of the Nile to the aid of the Greeks, one of her first moves was to occupy and fortify Crete. When the Greeks and British fell back before the German onslaught in April, the Greek king, part of his army and certain British divisions went to Crete and there prepared to make a stand against the Nazi forces. The attack came on May 20, 1941, when the German transport planes and gliders began dropping German soldiers from the air. In two days it was estimated that about 11,500 Germans had been ferried by air to Crete. The Germans occupied Candia and Retimo and Meleme airport but were driven out from the former two. German troops continued to arrive by air and the fiercest fighting of the war took place between May 24 and June 1. On the last day of May and June 1 the British evacuated 15,000 troops to Egypt. Their losses were placed at 13,000. Crete was occupied by Germany on June 2. German positions on the island were bombed by the Allies a number of times in 1943, and the air attacks were intensified in 1944. Allied forces landed in October 1944, and the invaders retired to the western end of the island. A tacit truce lasted until the armistice of May 8, 1945; but the surrender of 10,500 Germans to 500 British troops was not completed until May 26, in order to protect the invaders from massacre by the civilians.

Recovery after World War II depended largely upon the revival of exports. The island, which voted 70 per cent against the monarchy in the Greek plebiscite of 1946, suffered under frequent clashes between rightist government forces and guerrillas in 1947. In 1948 a group of American experts from the Rockefeller Foundation were engaged in a survey of the island to aid in the development of a public health program and to enable more efficient utilization of natural resources. In July of 1949 the United States Sixth Task Fleet in the Mediterranean held amphibious maneuvers on Crete.

CRETE, city, Nebraska, in Saline County; altitude 1,359 feet; on the Big Blue River; 19 miles southwest of Lincoln; on the Burlington and Quincy and the Missouri Pacific railroads; with a municipal airport, and good modern highways. In the midst of a grain-growing region, it makes flour and beer, and handles dairy products. Chemurgic equipment is manufactured here. Crete is the seat of Doane College (co-educational), and has a Carnegie library. First settled in 1865, Crete was incorporated as a village in 1871, and as a city in 1872. In 1886 its charter was revised. The government is administered by a mayor and council. The water power and lighting systems are all city-owned. Pop. (1930) 2,865; (1940) 3,038; (1950) 3,682.

CRETIN, krā-tān', Joseph, American ecclesiastic: b. Montluel, Ain, France, Dec. 19, 1799; d. St Paul, Minn., Feb. 22, 1857. He was ordained a priest in 1838 and was assigned a charge in his own diocese. His great desire was to work in the foreign missions, and when the opportunity to go to America presented itself he at once accepted. He was somewhat disappointed when he found himself among civilized people in Iowa instead of among Indians. He was made vicar general of Dubuque, a position which he held until 1851, when he was appointed bishop for the new diocese of Saint Paul. He found only nine priests in the diocese, but new parishes were soon opened, schools established, the orphans and the sick received attention, and provisions were made for the Indian tribes, the Ojibways and the Winnebagoes. In three years he increased the number of churches from 1 to 29, and to these added 35 stations.

Consult Shea, J. D. G., *The Hierarchy of the Catholic Church in the United States* (New York 1886).

CRETINISM, krē'tin-iz'm, a condition defined as an endemic symptom complex of bodily and mental disturbance occurring in population centers where endemic goiter is prevalent, the important manifestations being largely in the skeleton, skin, and nervous system, in which retardation of growth and mental development play a leading role and which cannot be attributed to another congenital or acquired disease. It is a somewhat puzzling matter when one considers that while endemic goiter is common in the United States and Canada, although less so than it was a decade or two ago, endemic cretinism does not occur at all in North America although common in Europe and Asia. The conception of endemic cretinism is that of a thyroid deficiency depending on a local endemic factor. This concept has not been accepted everywhere due to its being regarded by many scientists as incomplete. In the United States, the generic term cretinism is referred to often as juvenile, or childhood myxedema. The disease is chronic and is due to a diminution in functional activity of the thyroid gland secretion, beginning before birth or in the early weeks of life, which results in physical and mental deficiencies. The fundamental etiologic factors are unknown but several varieties of the malady have been described. These are: (1) the athyreotic type in which there is congenital absence of the thyroid gland; (2) the nongoiterous type in which a small mal-

functioning or nonfunctioning gland is present; and (3) a goiterous type in which the thyroid is large but cystic, with little glandular structure present, and incapable of secreting sufficient thyroxin to maintain the body economy. The first of these is the variety seen usually in the Western Hemisphere, the others being encountered almost entirely in Europe and Asia.

The symptoms and physical signs of the disease are observed a few weeks after birth and not at once, since the mother provides the child with sufficient thyroxin while it is in the uterus. At about 6 weeks the skin becomes dry and wrinkled, the hair coarse, brittle, and lacking normal growth. The child's face is broad and full and the eyes appear abnormally far apart. The tongue becomes thickened, and the infant drools continually. As the child becomes older it is noted that growth is retarded, the arms and legs being short and stumpy. Dentition is delayed and the child appears dull and apathetic. In the matter of prognosis for recovery there is always doubt. Theoretically, if the existence of the disease is suspected fairly early, it might be expected that the administration of dried thyroid gland would cause immediate cessation of symptoms and resumption of normal growth. As a matter of fact, usually by the time treatment is begun it is too late to prevent some permanent mental deficiency. The disease most often confused with cretinism is Mongolian idiocy, the appearance of the individual being somewhat similar in the two diseases. A differential diagnosis can be made by the therapeutic test since Mongolian idiocy does not respond to the administration of thyroid. See also GOITER: MYXEDEMA; THYROID GLAND.

HAROLD W. JONES, M.D.

CRETONNE, krê-tôn', a thick, firm cotton cloth with various textures of surface, printed on one side or on both with pictorial and other patterns, and used for curtains and for upholstering. Unlike chintz, it is hardly ever glazed.

CREUSA, krê-û'sä, the name of several celebrated women of Greek antiquity. (1) Daughter of Erechtheus, who, before she was married to Xuthus, gave birth to Ion, the fruit of an amour with Apollo. To her second husband she bore Achaeus. (2) The wife of Jason and the daughter of King Creon (q.v.) of Corinth. She was burned to death with her father by the magical poisoned diadem and robe given her as bridal gifts by Medea (q.v.). (3) The daughter of Priam and Hecuba, wife of Aeneas and mother of Ascanius. In the tumult of the conflagration of Troy, when Aeneas fled with the images of his gods, with his father and son, he lost her, and after he had sought her for a long time in vain her spirit appeared to him, saying that the mother of the gods had taken her to herself because she was not willing that she should leave Phrygia.

Consult Virgil's *Aeneid* (book 2, pp. 730-794).

CREUSE, krüz, a department of central France with an area of 2,163 square miles. Its capital is Guéret (pop. 1946, 10,192). Formed from parts of the provinces of la Marche, Poitou, Bourbonnais, Limousin, and Berry, its name derives from the Creuse River which traverses it in a northwesterly direction. The department contains two arrondissements (Guéret, prefec-

ture; Aubusson, subprefecture), 25 cantons, and 266 communes. Geologically it is a part of the Massif Central. The climate is rather severe with heavy precipitation, especially of winter snow, on its arid plateaus. The winters are long and cold, spring is a short season, but autumns are long and pleasant, as in Auvergne. The swollen rivers of winter and spring diminish to shallow streams in summer. A poor agricultural region, only a quarter of the department is under cultivation. There are many small farms, the chief crops being rye, buckwheat, and especially potatoes. Chestnuts of exceptionally fine quality are a specialty; together with potatoes they are used to fatten swine. Sheep are raised on the upland heaths and Creuse is France's leading sheep-raising department. Creuse wool was used in fabricating Aubusson tapestries and today is in demand by the carpet and cloth manufactories of that ancient town.

Every spring there is a migration of between 30,000 and 35,000 of the inhabitants to Paris and cities of eastern France seeking employment as masons. These are the *Limousins* (the provincial name having become a synonym for mason). Most of them return home for the winter months. Pop. (1946) 188,669.

CREUSE, a river of central France, right affluent of the Vienne. It rises on the southern border of the Department of Creuse, flows northwest, first through a narrow rocky valley, then through a not very fertile plain. Beyond Argenton in the Department of Indre it turns west, forms part of the southern boundary of Indre-et-Loire, and enters the Vienne below Port-de-Piles. Length, 255 kilometers.

CREUTZ, krûêts, COUNT **Gustav Phillip**, Swedish poet and statesman: b. Finland, May 1, 1731; d. Stockholm, Oct. 30, 1785. He was a member of the learned and elegant circle which surrounded the queen of Sweden, Louisa Ulrica, sister of Frederick the Great. His *Atis och Camilla*, an erotic poem in five cantos (1761), and his *Daphne* are considered masterpieces of Swedish poetry. He was appointed minister to Madrid in 1763, and to Paris in 1766. He remained in Paris for 17 years and became particularly acquainted with Jean François Marmontel and André E. M. Grétry. On April 3, 1783 he signed with Benjamin Franklin a treaty of amity between the United States and Sweden. His works and those of his friend Count Carl Gyllenborg are published together under the title *Vitterhets Arbeten af Creutz og Gyllenborg* (1795).

CREUZER, kroi'tsēr, (Georg) **Friedrich**, German philologist and archaeologist: b. Marburg, March 10, 1771; d. Heidelberg, Feb. 16, 1858. He studied at Marburg and Jena, and in 1802 became professor of philology at Heidelberg. In 1807 the professorship of ancient history was also conferred on him, and he held both chairs till his resignation in 1845. His works treat of mythological subjects and classical history, the most important of them being *Die historische Kunst der Griechen* (1803); *Dionysus* (1808); *Symbolik und Mythologie der alten Völker, besonders der Griechen*, 4 vols. (1810-1812); and an edition of Plotinus (1835). His symbolical theory of mythology gave rise to a controversy with Gottfried Hermann,

Voss and others. With G. H. Moser, he edited several of the works of Cicero. A collection of his writings was published in 1854 under the title *Opuscula Selecta*.

Consult Stark, B., *Friedrich Kreyzer, sein Bildungsgang und seine bleibende Bedeutung* (Heidelberg 1875), and Sandys, Sir J. E., *A History of Classical Scholarship*, vol. 3 (Cambridge 1908).

CREVASSE, krē-vās', a deep fissure or crevice in a glacier, caused by movement of the parts at unequal rates or by passage over a rough surface. In the United States the term is also used for a breach in an embankment or levee. See also GLACIER; LEVEE.

CREVAUX, krē-vō', Jules Nicolas, French explorer: b. Lorquin, Lorraine, France, April 1, 1847; d. South America, April 24, 1882. He took part in the Franco-Prussian War, and was later made a surgeon in the navy. In 1876 he turned his attention to the exploration of South America; he first crossed the Tumuc-Humac Mountains; then explored the valley of the Oyapock and its tributaries and several tributaries of the Amazon. In 1880 he crossed the cordilleras of the Andes and reached the Orinoco by the Guaviare River, a tributary never before explored. He returned to France for a short time, but in 1882 started on another expedition, intending to explore the upper part of Paraguay and some of the southern tributaries of the Amazon. On arriving at Buenos Aires he became interested in a plan for the exploration of the Gran Chaco and the Pilcomayo River, and joined an expedition for that purpose. He and all but two of his companions were murdered by the Tobas Indians on the banks of the Pilcomayo. An account of his explorations was published under the title *Voyages dans l'Amérique du Sud* (1883).

CREVECOEUR, krēv-kūr', Michel Guillaume Jean de, French essayist: b. near Caen, Normandy, France, Jan. 31, 1735; d. Sarcelles, near Paris, Nov. 12, 1813. After receiving part of his education in England he migrated to Canada in 1754, served under Louis Montcalm de Saint-Véran in the French and Indian War, and explored the Great Lakes and Ohio River regions. He landed in New York City in 1759, traveled for a decade in New York, Pennsylvania and the Carolinas, then in 1769 married Mehitable Tippet of Yonkers, and settled on a farm in Orange County, N. Y. During the succeeding 11 years of pioneer farming life he wrote the essays which have made his reputation as a delineator of the rural American scene. He was deeply moved by the plight of the poor independent farmer in a province where the feudal manorial system of England had been grafted a century before on the patroonal system of the Dutch. Despite his sympathy for the common people and ardent love of personal liberty, on the outbreak of the American Revolution he favored the Loyalist side, disgusted with profit patriots who were "perpetually bawling about liberty without knowing what it was." In September 1780 he embarked for France. His great work, the sheaf of essays entitled *Letters from an American Farmer*, was published in London over his pseudonym, J. Hector St. John, in 1782. A French version, expanding the original essays, was issued in Paris the next year. After a three-years' absence he returned to America and debarked in New York, Nov. 19, 1783, only to find his wife dead, his

children vanished, and his farmhouse burned in an Indian raid. Eventually he found his children. Appointed French consul in New York, he devoted himself to cementing the friendship between France and the United States born of the war alliance. He corresponded with Washington, was a friend of Franklin, Jefferson, and other leaders of opinion. He wrote extensively for the newspapers over the signature "Agricola." It was his boast that he had introduced to American cultivation such forage crops as alfalfa, sainfoin, and the vetches. The Rhode Islanders who settled a new town in Vermont in 1786 named it Saint Johnsbury in gratitude for Crèvecoeur's assistance. In 1790 he took final leave of his adopted country and returned to France. Some of his unpublished manuscripts, discovered by H. L. Bourdin in 1922, were published in 1925 under the title, *Sketches of Eighteenth Century America*.

CREW, krōō, Henry, American physicist: b. Richmond, Ohio, June 4, 1859. Educated at Princeton University and Johns Hopkins, he was appointed professor of physics at Northwestern University in 1892, and became a distinguished teacher and research physicist, especially in the field of spectroscopy. He retired from the faculty of Northwestern University in 1930 and became chief of the division of basic sciences of the Century of Progress Exposition in Chicago. He is the author of *Principles of Mechanics* (1908), *General Physics* (1908), *Rise of Modern Physics* (1928), and a translation of Maurolycus' *Optics* (1940).

CREW. See NAVAL TERMS.

CREWE, 1st MARQUESS OF (ROBERT OFFLEY ASHBURTON CREWE-MILNES), English statesman and diplomat: b. London, England, Jan. 12, 1858; d. Leatherhead, June 20, 1945. The son of Richard Monckton Milnes, 1st Baron Houghton, he succeeded to the title in 1885. He was educated at Harrow and at Trinity College, Cambridge University, and in 1883-1884 served as assistant private secretary to the 2d Earl Granville, secretary of state for foreign affairs. He was lord in waiting to Queen Victoria in 1886, and lord lieutenant of Ireland from 1892 to 1895. In that year he was created earl of Crewe. From 1905 to 1908 he served as lord president of the council, in 1908 and again from 1912 to 1915 as lord privy seal, and from 1908 to 1910 as secretary of state for the colonies. In 1911 he was created a marquess. After serving as secretary of state for India (1910-1915), he again became lord president of the council, remaining in this office until 1916, when he became president of the Board of Education. In 1917 he was chairman of the London County Council. He served as ambassador to France from 1922 to 1928, and as secretary of state for war in 1931. From 1936 until 1944 he was leader of the Liberal Party in the House of Lords. His published works include *Stray Verses* (1889-1890) and *Lord Rosebery* (1931).

CREWE, municipal borough, England, situated in Cheshire, 30 miles southeast of Liverpool and 158 miles northwest of London, on the main line of the London Midland region of the British Railways. Most of its residents derive their livelihood from the town's large railway works,

which include steel mills, repair and machine shops, and locomotive and railroad car plants. Other establishments produce chemicals and clothing, and process food. Near the town is Crewe Hall, now the property of the Duchy of Lancaster.

A mere hamlet in 1840, Crewe developed rapidly as a center of the then London & North-Western Railway Company, and was incorporated in 1877. Pop. (1951) 52,415.

CREWELWORK, a type of embroidery (q.v.) in which designs are sewed with colored silk or woolen yarn, loosely twisted, on linen or similar materials.

CREWS, krōōz, **Laura Hope**, American actress: b. San Francisco, Calif., 1880; d. New York, N. Y., Nov. 13, 1942. She made her debut at the age of four, and later supported such outstanding performers as Eleanor Robson, Henry Miller, John Drew, and Sir Herbert Tree. Her first hit was in *The Girl I Left Behind Me* (1900); another early success was *The Great Divide* (1906). In 1921 she was in the original cast of the first A. A. Milne play to be presented in New York, *Mr. Pim Passes By*. She created the role of the mother in Sidney Howard's *The Silver Cord* (1926), and played in the Theatre Guild's production of Pirandello's *Right You Are If You Think You Are* in 1927. Her last stage appearance was in *Arsenic and Old Lace* (1942). Beginning in 1929, she appeared in many motion pictures, including *Gone With the Wind*, *Camille* (with Greta Garbo), and *The Man Who Came to Dinner*.

CRIBB, Tom, English pugilist: b. Hanham, Gloucestershire, England, July 8, 1781; d. Woolwich, May 11, 1848. Known as the "Black Diamond" because he had worked as a coal porter, he fought his first professional fight against George Maddox at Wood Green in 1805. Later the same year he suffered the only defeat of his career at the hands of George Nicholls. Cribb conquered the famous ex-champion Jem Belcher in forty-one rounds in 1807, and went on to win the championship from Bob Gregson in 1808. He defended his title twice against Tom Molineaux, an American Negro, in 1810 and 1811. For the next decade he held that championship unchallenged, and retired undefeated in 1821, with the honorary title of champion for life.

CRIBBAGE, a card game whose invention was attributed by John Aubrey to Sir John Suckling (1609-1642, q.v.), but which probably derived from a much earlier game. It may be played by two, three, or four persons. In the four-handed game two persons play as partners against the other two. The two-handed game, considered the best, is here described in greatest

detail. In all forms of cribbage a complete 52-card deck is used, and 61 or 121 points constitute a game. A player scoring 61 points before his opponent scores 31, or 121 points before his opponent scores 61, is credited with winning two games. This is called a lurch, but many players disregard the rule.

Rank of the Cards.—The king is high, and the ace is always low. In the count of the cards, however, all face cards are counted as 10's, and the other cards according to the number of spots or pips on each.

The Deal.—Before play begins, the players cut for deal, and low deals. The cards are then shuffled; either player may do the shuffling, but the dealer always shuffles last. The dealer's opponent cuts the cards, and the dealer deals six cards, one at a time alternately, to each player, beginning with his opponent. The loser of the game deals the next hand.

Misdealing.—Among the various errors classified as misdeals, each of which carries a penalty of 2 points to be scored immediately by the dealer's opponent, are (1) failure to have the cards cut before dealing; (2) exposure of a card while dealing; (3) dealing too many or too few cards to a player; and (4) dealing a card incorrectly (that is, to the wrong person), and failing to correct the error before another card is dealt.

In the event of a misdeal, the player's opponent may call for a new deal by the original dealer, but, except when too many or too few cards have been dealt, he must announce his decision before looking at his own cards. If the dealer has the incorrect number of cards, his opponent can decide whether or not the deal stands; and if he decides in the affirmative, he has the right to draw the superfluous cards: if the dealer has too many—from the latter's hand, placing them on the top of the pack and looking at them if the dealer has seen them. If the dealer does not have sufficient cards, and the deal is allowed to stand, he makes up the deficiency from the top of the pack. If the dealer's opponent is the victim of the misdeal, he must decide before looking at his hand whether or not he wishes the deal to stand. If he decides in the affirmative, he places his surplus cards, if he has too many, on the top of the pack; if he has too few, he requests the dealer to supply the deficiency from the top of the pack.

A new deal is mandatory if a card is faced in the pack, or if the pack is discovered to be imperfect. In such cases the original dealer re-deals. If a player deals out of turn, the deal may be stopped at any time before opposing player takes up his cards. The penalty for dealing out of turn is 2 points to be scored by the opposing player, but if the latter has taken up his hand before attention is called to the improper deal, it stands, and no penalty can be exacted.

The Crib.—In the two-handed game, after

Cribbage score board.

completion of the deal, each player discards two cards, face down on the table. These discards constitute what is called the crib, and belong to the dealer, who, however, makes no use of them until after all cards in the hands have been played. He then counts and scores all points contained in the crib in combination with what is called the starter.

The Starter.—After the discard, or formation of the crib, the nondealer again cuts the cards, and the dealer then turns the top card of the bottom pack face up on the reunited pack. This turned-up card is called the starter in the United States; in England it is sometimes called the start or turnup. If the starter happens to be a jack, the dealer immediately scores 2 points for "his heels." If he fails to peg his score before playing a card, he forfeits his points. The starter is never used during the play of the hands, but only in counting the hands and the crib after all cards have been played.

Objects of the Game.—The objects of cribbage are to form various counting combinations of the cards, such as pairs, triplets, fours, sequences, and fifteens. These may be formed by the fall of the cards during the play, or they may be found in the hands or in the crib, in combination with the starter, after the play is over.

Play of the Cards.—After the starter has been turned, the nondealer plays a card from his hand face up on the table immediately in front of himself, announcing as he lays it down the number of pips appearing on it. Face cards are announced as 10's. The dealer then plays a card face up in front of himself, but instead of simply announcing the number of pips on it, he adds its value to the value of the card played by his opponent and announces the total. Thus, if the first card played was a 5 and the second a 6, the player of the latter announces "11." This manner of playing and totaling the values of the cards played is continued until all the cards have been played, or until neither player can play a card without passing 31. If a player whose turn it is to play has no card in his hand that can be played within the limit of 31, he so states, and thereafter his opponent, if he can do so, continues to play until the count reaches 31, or until he too can no longer play without passing 31. This is called a go. The player who approaches nearest to 31 during the play scores 1 point; if he reaches exactly 31, he scores 2 points. After 31 has been reached or a go has been declared, the players turn the cards face down in front of themselves, and the play is continued with the cards remaining in their hands, just as though no cards at all had been played, the player entitled to the next play leading off. The players always play alternately except when one announces he can no longer play without passing 31, and his opponent has cards which can still be played.

Points Which May Be Scored in Play.—

Fifteens.—If a player lays down a card which makes the count of the cards played exactly 15, he scores 2 points, announcing "fifteen—2." If, for example, the first card played was a 7, the second a 3, and the third a 5, the player of the last card scores 2 points for the fifteen.

Pairs.—A pair is made when a player lays down a card equaling in numerical value that of the last card played, as a 5 after a 5, or a queen after a queen. The player forming the pair scores 2 points.

Triplets.—Triplets are formed when three

cards of the same denomination are played one after the other. They are called pairs royal, and the player forming a triplet scores 6 points for the three pairs which can be made of the three cards. If, for example, the three cards are the 5 of hearts, 5 of spades, and 5 of diamonds, the 5 of hearts and 5 of spades make one pair; the 5 of hearts and 5 of diamonds, a second pair; and the 5 of spades and 5 of diamonds, a third.

Fours.—Called double pairs or double pairs royal, fours are made when four cards of the same denomination are played, one after the other. The player playing the fourth card scores 12 points for the six pairs which can be made from the four cards. These 12 joints are scored in addition to the 6 points which his opponent may have scored when the triplets (the first three cards played) were formed, just as the maker of triplets scores 6 points even though his opponent may have just scored 2 points for forming a pair.

Sequences.—Sequences, scoring 1 point for each card in the sequence, occur when three or more cards in numerical order are played, even though they were not played in numerical rotation. In other words, 9-7-8 is as much of a sequence as 7-8-9. A three-card sequence scores 3 points, and a four-card sequence 4 points, in addition to the 3 points which the opposing player possibly, or very probably, scored previously. The ace being low, the ace, king, and queen do not make a sequence, but the ace, deuce, and trey do. The king, queen, and jack make a sequence, although all rank as 10's in the count of the cards. An intervening card or duplicate breaks the sequence; thus, 2-3-6-4 cannot be counted as a sequence, nor can the second 5 be so counted in 3-4-5-5, the first 5 breaking the sequence insofar as the second 5 is concerned.

Maximum Count.—With respect to the formation of pairs, triplets, fours, and sequences, it must be remembered that in no case may the count of the cards exceed 31. The various counting combinations may be made when the players play alternately, or by one player playing from his own hand all the cards that will play within the limit of 31 after his opponent has announced that he can no longer play without passing 31.

Compound Scores.—It is possible to make more than one of the counting combinations at the same time. Thus, 5-5-5 counts as three pairs, scoring 6 points, and also as a fifteen, scoring 2 additional points; 4-5-6 counts as a three-card sequence, scoring 3 points, and also counts as a fifteen, scoring 2 additional points.

Count of the Cards.—When all cards have been played, the hands are taken up and counted aloud, the nondealer counting first and pegging his score as he counts. Next the dealer counts his hand, pegging his score as he counts, and then counts the crib. In counting the hands, each player includes the starter as part of his hand, so that he actually counts five cards. Likewise, the dealer, in counting the crib, includes the starter in the count. The combinations in the hands which entitle the players to score are fifteens, pairs, triplets, fours, sequences, and flushes (all cards of the same suit). In addition, if either player holds the jack of the same suit as the starter, he scores 1 point for "his nob."

Fifteens.—In counting the hands and the crib, the player is entitled to count all combinations of cards which, taken together, make exactly 15, and scores 2 points for each fifteen so made. All face cards are counted as 10's, so that a

player holding a king, queen, or jack and a 5, counts fifteen and scores 2 points. If he holds a face card and two 5's, he counts two fifteens, and so on. Holding two face cards and two 5's, he can count four fifteens and scores 8 points.

Pairs, Triplets, and Fours.—These are counted and scored as in play, pairs scoring 2 points each; triplets, 6 points; and fours, 12 points.

Sequences.—As in play, sequences score 1 point for each card in the sequence of three cards or more, but in counting the hands a card of one denomination may be substituted for another card of the same denomination and counted as another sequence; thus, 3-4-5 counts as two sequences, and if the starter happened to be a 5 also, three sequences could be counted.

Flushes.—If all cards in the hand belong to the same suit, it is counted as a flush, and the holder scores 1 point for each card. If, in addition, the starter is also of the same suit, it counts as a five-card flush, scoring 5 points. In counting the crib, however, a player cannot count a flush unless the starter as well as the other four cards all belong to the same suit.

Maximum Count.—The highest possible score that can be made on one hand is 29—for holding three 5's and the jack of the same suit as the starter, with a 5 turned up. Such a hand counts 12 points for the fours, 8 points for the four fifteens that can be made with the jack and the four 5's, 8 points for the four fifteens that can be made from the four 5's, and 1 point for "his nobs."

Score Board.—Points made in play and in the count of the hands and the crib are scored on a board into which four parallel rows of holes—30 holes to the row—and 2 extra holes, 1 in the center of each end, called game holes, have been drilled. This board is placed between the players, who usually score from opposite ends. Each player is given two pegs which fit into the holes in the board. As points are made, the player making them moves his back peg forward, indicating the points made and the total score.

Five-Card Two-Handed Cribbage.—As in the six-card game, the cards are dealt alternately, one at a time to each player, and each discards two into the crib, so that each player holds only three cards in his hand. On the first hand played in each game the nondealer scores 3 points to compensate for the advantage which the deal gives his opponent. When either player reaches 31 or says "go," the play stops, the score for 31 being 2 points, and that for go 1 point. Thereafter, the hands and the crib are shown and counted as in the six-card game.

Three-Handed Cribbage.—Cards are cut for deal, which passes to the left. Five cards are dealt to each player, one at a time, and each player discards one card for the crib. Points are scored on a triangular board containing three double rows of holes (30 holes to the row), and a game hole for each player. Points are scored and the game is played as is the two-handed game.

Four-Handed Cribbage.—Two of the players play as partners against the other two. One player on each side does the scoring, and the other players are not permitted to touch the board or the pegs. Five cards are dealt, one at a time, to each player, beginning with the player to the dealer's left, and the deal passes to the left. Each player discards one card into the crib, which belongs to the dealer. The player on the dealer's left cuts for starter. He also begins the

play, which passes to the left, the dealer playing and counting his hand last.

CRICHTON, kri't'n, James (known as THE ADMIRABLE), Scottish scholar: b. Aug. 19, 1560, d. Mantua, Italy, July 3, 1582. The elder son of Robert Crichton, lord advocate of Scotland, he was probably born on his father's estate at Elioock, Dumfries. He entered St. Andrews University at the age of 10, and soon distinguished himself for his remarkable learning and linguistic ability. He received his B.A. degree in 1574, and his M.A. in 1575. In that year he was selected to be a companion of the young king, James VI in his studies. At the end of 1577, Crichton went to France, where he continued his studies and served for two years in the French Army. A handsome youth and a skilled athlete and swordsman, he won widespread admiration. According to one account, he offered to answer questions in 12 languages on any topics in the sciences and liberal arts, and did so on the appointed day. In 1579 he went to Genoa, where he was well received and published a Latin address to the Senate. At Venice, in the following year, he was introduced to the doge and the Senate. There and in Padua, where he went in 1581, he won acclaim for his Latin verses and his brilliant extemporaneous discourses on philosophy, theology, and mathematics. In Venice he made the acquaintance of Aldus Manutius, who introduced him to other scholars, with whom he debated on learned subjects. In Padua he challenged the professors of the university to a debate on Aristotle and mathematics, in which he came off handsomely. Early in 1582 he went to Mantua, where he became tutor to Vincenzo Gonzaga, son of the duke. Attacked one night by a party of armed and masked men, Crichton recognized one of them as his pupil and offered him his sword. The young prince immediately ran him through with it. This account of his death has been corroborated by documents in the archives of Mantua, and later references to a James Crichton in Milan would seem to pertain to another Scot of the same name.

CRICHTON-STUART, John Patrick. See STUART.

CRICKET, the name applied to a family of insects (Gryllidae), belonging to the order Orthoptera. Crickets differ from grasshoppers and locusts in that the wings lie flat over the abdomen, which is broader than it is high. The antennae are long and tapering, the tarsi are divided into three segments, and the ovipositor is spear or awl shaped. There is a pair of unsegmented cerci at the apex of the abdomen.

The common field crickets belonging to the genus *Gryllus* are usually blackish or dark brown, but a few are brown or yellowish brown. Most of them reach maturity in the late summer or autumn. Their chirp, or song, is produced by rubbing the upper wings together. On the costa or front edge of each of these is a section bear-

ing a many-toothed ridge; when the teeth are rubbed rapidly together the song, which is different in each species, is produced. The house cricket, *Gryllus domesticus*, prefers the warmth of a household, where it keeps up its cheerful chirping for the greater part of the year. The presence of house crickets in a home has been traditionally regarded as an omen of good luck.

Crickets are mostly vegetarians, but some feed on other insects, and they may damage starched clothing. Poisoned baits and DDT sprays will destroy them. See also FIELD CRICKET; MOLE CRICKET; TREE-CRICKET.

CRICKET, the national game of England, also played in the United States, Great Britain, Australia, South Africa, New Zealand, India, Canada and West Indies. Two opposing teams with eleven players on each side aim to make the highest number of runs. Wickets, consisting of three stumps, are pitched in the ground 22 yards apart. (F.B.)

Origin.—Cricket, like other bat and ball games, was not "invented," but slowly evolved from ancient Egyptian folk-fertility rites. Efforts to connect it with the Scottish "Cat and Dog," a 15th century "Handyn Handoute," the French Crique, and an uncertain "Creag" have not been successful, but all such games are related.

The name cricket probably comes from the Saxon *crice*, since there are so many forms of this word for the instrument used in the early generic games of club and ball. But the immediate ancestor of the game is stoolball, an Easter ball custom, associated with the church. Stoolball games were the times *par excellence* for courting between youths and maidens who participated; a characteristic definitely relating the game with the ancient springtime fertility rites.

In stoolball, one player threw a ball at an upturned three-legged stool, defended by another player. It was perhaps known in 1330, certainly by 1450. Later a second stool was added. A stool is also called a cricket, and it is possible that this was the origin of the name. However, this use of the word was not noted till 1643, whereas the earliest known reference to a game called cricket is in 1598, in Florio's Italian-English dictionary, *A World of Words*. Until further evidence is found, we conclude that the game came from stoolball, as did baseball (q.v.), but the name came from *crice*, the Saxon stick. Modern cricket came of age with the printing of the first rules in 1744. (R.W.H.)

The Modern Game.—Cricket stands pre-eminent in England among the many outdoor pastimes pursued during the summer months. Cricket is not solely a game of skill; chance is also a factor, and condition of the pitch and weather are so influential that in some cases a side which appeared to have little prospect of success has come out victorious.

Cricket was originally either single wicket or double wicket, but as single wicket is now only played by boys or when numbers are few, we can safely confine our attention to the double wicket. For a double wicket game eleven players on each side are necessary. After the captains have tossed a coin to settle who shall have choice of innings, the captain of the fielding side places his men, and the other captain usually opens the innings by sending in two of his surest and safest batsmen to defend the wickets and to make the runs. The purpose of the opening bats-

men usually is to take the edge off the fresh bowling to make way for aggressive and big-hitting batsmen.

The placing of the field depends entirely on the style of bowling, whether it be fast, medium-pace, or slow.

Cricket field set for a fast bowler.

Cricket field set for a slow bowler.

The field having been duly placed, and the batsmen having taken their stand, the umpire calls "play," and the bowler sends down his first ball. After six balls have been delivered from one wicket (in some countries eight are bowled; in England eight is optional, but six balls are used in all first-class matches) the umpire calls "over," and the field is reversed subject to slight positional changes at the discretion of the captain or the bowler. These "overs" continue to be bowled from alternate ends until the eleven batsmen have been disposed of.

When the tenth wicket falls, the remaining batsmen automatically retire and the other side now comes to bat. Runs are made by the bats-

Cricket field set for a modified slow "off theory" bowler.

Cricket batting stance.

man driving the ball far enough away to give him time to change places with the batsman at the other end, before the ball returns. Each change constitutes a run. Six is the largest number of runs that can be made from a single hit, that occurring when the ball is driven clear off the pitch or out of the grounds. A six could also be run by a fielder overthrowing when returning the ball to the wicket-keeper.

The task of the bowler is to try in every possible way to dislodge one or both of the bails resting on top of the stumps defended by the batsman, or else to tempt him into hitting the ball into the air so that it may be caught before bouncing by one of the fielders.

Besides being bowled or caught, a batsman may be "run out," that is, have his wicket hit by the ball while he is attempting to score a run, or he may be "stumped-out," which is to have the same thing happen when he rashly steps out of his crease to strike a ball and misses, enabling the wicket-keeper to whip off the bails. The batsmen can also be out "leg before wicket," which means that his legs have been struck by a ball that normally would have struck his wicket. He can also be out, knocking off the bails with his own bat.

The ball usually comes to the batsman on the first bounce and the bowler's skill is shown in varying the pitch, speed and direction of the ball so that the batsman is uncertain whether to play forward or back. One of the best forms of bowling is what is known as "bowling with the break," the peculiarity of which consists in that the ball after striking the ground does not continue straight on, but swerves or spins sharply to right or left like a "cut" tennis ball.

Cricket bat.

Proper grip.

which normally could not be finished in the time allowed.

Three full days are usually required for a first-class two-innings match. Bad weather, or a collapse by the batsmen of one team, could curtail a first-class match to two-days, or even one-day's play. Consistent rain would prevent a match being started. In test matches in Australia the games are sometimes played to a finish and go

The art in batting is to play with a "straight back," that is, as far as possible to swing the

on for many days. In Canada there are clubs in many cities, towns and villages.

Revision of the Laws.—The Marylebone Cricket Club (M.C.C.) prepared the final draft of their proposals for revised laws of cricket to be submitted to a special general meeting at Lords on May 7, 1947. The new laws were scheduled to come into effect in the English season of 1948.

There are not any drastic alterations. In fact, the M.C.C. removed some ambiguities and put the laws into logical sequence. Thus the 47 laws, a reduction of 13 from the existing number, are divided into five sections: (1) players, umpires, and scorers; (2) implements of the game and the ground; (3) care and maintenance of the pitch; (4) conduct of the game, and (5) duties of umpires.

There are two outstanding revisions. The first means that no longer will a wicket be held to be "down" if a bail merely had been dislodged. The new law stipulates that a bail must be separated from the top of the stumps, and a note has been added covering the possibility of a ball lodging between two stumps. In this case the wicket also will be considered broken. To avoid any danger of the bails lodging together over the center stump, each is to be shorter by one eighth of an inch.

The other important revision concerns the last over of a match. The M.C.C. propose that this shall be played right out at the request of either captain, even if a wicket falls after "time" has been reached. Under existing law, if a wicket goes down within two minutes of time, stumps are pulled unless the incoming batsman claims his right to bat for the time remaining, and if a batsman is out after "time" has been reached, play ceases at that point.

As the present rules concerning "stumping" and "run out" can confuse umpires, the M.C.C. now state that the striker is stumped "if, in receiving a ball, not being a no-ball, delivered by the bowler, he be out of his ground otherwise than in attempting a run, and the wicket be put down by the wicket-keeper without the intervention of another fieldman. Only when the ball has touched the bat or the person of the striker may the wicket-keeper take it in front of the wicket for this purpose." The proposed laws make it clear that the striker, in playing at a ball, may not be given "run out" when the wicket is put down by the wicket-keeper unless in the opinion of the umpire he attempts a run which is, in fact, the original conception of the rule.

In making it clear that the striker has the right to guard his wicket without interference, M.C.C. have insisted that the wicket-keeper shall remain wholly behind the wicket until the ball touches the bat or person of the striker. This will eliminate, among other things, the difficulty for an umpire of defining the difference between a snick and a ball struck up. Since the wicket-keeper cannot anticipate that a snick justifying his taking the ball in front of the wicket will occur, he will not be tempted to do so, thereby risking losing the opportunity of stumping, especially as he must not interfere with the striker.

Both in the law as rewritten, and in a note on the law, stress has been laid on the fact that the height of the point of impact, even though above the level of the bails, is immaterial provided the ball would hit the wicket. It has also been clarified that the word "pitched" includes a full pitch.

To give umpires full power to prevent bat-

men obtaining leg-byes by deliberately deflecting the ball, M.C.C. have altered the note which says that "if the striker kicks the ball wilfully, no runs shall be scored" to "if the striker wilfully deflects the ball with any part of his person, no runs shall be scored and the batsmen may not change ends."

Although umpires have always possessed the power to stop a bowler running down the wicket after delivery and causing such damage as might unduly assist the bowler at the other end, they have now received written authority to forbid this as "unfair play."

The M.C.C. have defined the pitch which is named as the area of ground between the bowling creases, 5 feet in width on either side of the line joining the center of the wickets. After the toss for innings, the umpires are to control the use and maintenance of this.

FRANK BUTLER.

CRICKET FROG, a small frog (*Acris gryllus*; northern species are variety *crepitans*), abundant throughout the warmer parts of the United States, east of the plains, and noted for its rattling cricketlike cries in spring. It is about an inch long, brownish, with a blackish triangular patch between the eyes, the borders of which are light colored, continued as a dorsal band to the rear end of the body; throat in spring yellow and legs barred; but all these colors change with surroundings, as the species possesses the power of metachrosis in a high degree. "The note of this species," says Cope, "may be exactly imitated by striking two marbles together, first slowly, then faster and faster, for a succession of about 20 or 30 beats. The noise cannot be heard at a very great distance . . . it keeps on the high grass in and around marshy places, seldom if ever ascending trees or bushes. When pursued it leaps with prodigious agility and hides under water." Their eggs are deposited in April, in little masses attached to the blades of coarse grass. A short time afterward all the great numbers which make the marshes so noisy in April and May die off, so that until the eggs hatch and the young "peepers" develop late in August, the species is practically extinct. The cricket frog feeds on insects, the larvae and pupae of crickets and grasshoppers. Its ability to make prodigious leaps enables it to capture many flying insects. In the eastern United States it has not been reported north of southern New York and Connecticut. Consult Dickerson, *The Frog Book* (New York 1906); Wright, A. H., and Allen, A. A., "Notes on the Breeding Habits of the Swamp Cricket Frog," *American Naturalist*, 42:39-42 (1908); Wright, A. H., *Frogs: Their Natural History and Utilization*, Bulletin, Bureau of Fisheries, Doc. 888 (1920); Morgan, A. H., *Field Book of Ponds and Streams* (New York 1930).

CRICKET ON THE HEARTH, The, a Christmas book by Charles Dickens, published in 1846. The title is suggested by the singing match between the kettle and a cricket on Dot Peerybingle's snug little hearth, a contest which the cricket wins. John Peerybingle, carrier, is led to doubt the sincerity of his wife Dot by venomous old Tackleton who is about to marry young May Fielding. The Peerybingles' eccentric elderly boarder is discovered by John to be actually a bright young man in disguise. Influenced by the cricket on the hearth, John decides to pardon his wife whose guilt he no longer doubts. All ends happily when the mysterious young man turns out to be Edward, son of Caleb Plummer, the toy maker, come home from South America just in time to save his sweetheart May from marriage to Tackleton. Other characters include Caleb's blind daughter Bertha, and Tilly Slowboy, a most loving but thoroughly incompetent nurse. In 1859 Joseph Jefferson played the part of Caleb Plummer in Dion Boucicault's dramatization of the story. It became one of his favorite roles performed for over forty years in the United States, Australia and England. The Viennese composer Carl Goldmark composed an opera founded on Dickens' story entitled *Das Heimchen am Herd* which was produced in Vienna and Berlin in 1896, and in English versions in England in 1900 and the United States in 1910. Still another operatic version was composed by Sir Alexander Campbell Mackenzie and produced at the Royal Academy of Music, London, in 1914.

CRIDGE, Edward, Canadian bishop: b. Devonshire, England, Dec. 17, 1817; d. Victoria, British Columbia, Canada, May 6, 1913. A graduate of St. Peter's, Cambridge, he was ordained priest in the Church of England (1849). Appointed chaplain of the Hudson's Bay Company in Vancouver Island in 1854, he resigned his rectorship of the church at Victoria in 1874, joined the Reformed Episcopal Church and, in 1875, was elected bishop, an office he held until his death. His diocese included all Canada and the United States west of the Rocky Mountains. He published *As it was in the beginning* (Chicago 1890).

CRILE, krīl, **George Washington**, American surgeon: b. Chile, Ohio, Nov. 11, 1864; d. Cleveland, Ohio, Jan. 7, 1943. He obtained his bachelor degree at Ohio Northern (1884) and M.D. at Western Reserve University (1887), then studied in Vienna, London, and Paris before commencing practice in Cleveland. In 1905 he performed the first direct blood transfusion, and the same year discovered that adrenalin could restore the heart beat of an apparently dead person. He perfected blood transfusion techniques, and performed the first successful thyroid operation, a type of surgery in which he was unexcelled. His most important medical discovery was nerve-block anaesthesia. In 1921 with others he founded the Cleveland Clinic for clinical and research activities. Among his many works are *Origin and Nature of the Emotions* (1915); *Man, An Adaptive Mechanism* (1916); *Problems of Surgery* (1928); *Intelligence, Power, and Personality* (1941).

CRILLON, krē-yôn', **Louis Balbis de Ber-ton de**, French soldier, known as **L'HOMME SANS PEUR** (THE FEARLESS): b. Murs, Provence, Mar.

5, 1543; d. Avignon, Dec. 2, 1615. His family was of Piedmontese origin. As aide-de-camp to the duke of Guise he aided importantly in the reconquest of Calais and Guines (1557), was present at the capture of Rouen (1562), and fought in the principal battles of the religious wars. At Lepanto (1571) he performed prodigies of valor and, though wounded, was appointed to carry news of the great victory to the pope and the king of France. Again wounded at the siege of La Rochelle (1573), he later served in Poland with the duke of Anjou. Wounded at the taking of La Fère (1580), he was promoted *mestre de camp* (colonel), then lieutenant-colonel general. After the day of the Barricades he defended Henry III and followed him to Blois. The king, wishing to rid himself of the duke of Guise, tried to persuade Crillon to assassinate him, but the hero scorned such foul play. In 1589 he defended the bridge of Tours against the duke of Mayenne. Though wounds prevented him from fighting at Arques, he fought at Ivry (1590). In 1600 with Sully he commanded the army of Savoy, but soon after retired to Avignon. Henry IV's affectionate message to him after Arques was epitomized by Voltaire in the memorable: "Hang yourself, brave Crillon: we fought at Arques, and you were not there."

CRIME, a word signifying in its legal acceptation any act to which the law attaches a penalty or punishment, without any reference to its moral turpitude. The common-law division of crimes was into treason (q.v.), felony (q.v.) and misdemeanor (q.v.). In the United States treason is usually classed as a felony and the distinction between felonies and misdemeanors hinges upon the degree of punishment prescribed for the crime, a felony being punishable by loss of life or by incarceration in a state prison for at least a year and by the deprivation of civil rights, and a misdemeanor being punishable by a fine or by imprisonment in a workhouse or by both. To constitute a crime, there must first be an act, since a mere opinion or intention, however wrong from a moral or religious point of view, if not carried into an act, cannot be treated as a crime, although the criminality of the act, when done, may be partially or entirely dependent upon the intention of the actor. The true and only reason for making any given act a crime is the public injury that would result from its frequent perpetration. Each individual instance constituting an individual injury, frequent repetition would make it a social injury. Society accordingly takes the most efficient measures for its prevention by appealing to the fears of mankind. The crime is first accurately defined, the requisite punishment attached to it, and then government itself becomes a party to the prosecution of the offender, in order to ensure the carrying into effect of the penalty. While the only legitimate object of punishment is to protect society against a repetition of crimes, humanity dictates that the reformation of the offender should also, if possible, be effected. But as government has no concern with men, except as members of society, it is obvious that their moral improvement can never be made the primary object of punishment. Self-protection is at once the foundation and the end of the power exercised by society in punishing its members. In preventing the repetition of crimes, punishment is designed to operate both upon the individual offender and

upon the community at large. Upon the offender himself it operates by physically disabling him from repeating the offense, or by dissuading him from it through the recollection of past suffering, or by both of these means. Upon the community at large it operates only by the terror of example. Consequently it follows that the mode and degree of punishment are to be determined not so much by the abstract nature of the offense as by the probability of its frequent repetition; and also that no act should be punished at all, the repetition of which does not injuriously affect the temporal welfare of society. Insanity, infancy, coercion, or duress may excuse an act otherwise criminal in the degree that they destroy the voluntary nature of the act, which is therefore performed by the agent without specific criminal intent. See also *CRIMINOLOGY*; *FINGERPRINTING*.

CRIME AND PUNISHMENT, a Russian novel by Fyodor Mikhailovich Dostoyevsky, considered his masterpiece in fiction. An outline of the story, a psychological study of a murderer, may reveal why its publication in 1866, was a great literary event.

Rodion Raskolnikov, a law student in the University of Petersburg, has written an article on crime. As he has not been informed that the article was accepted, and as the small pittance that his mother and sister have been in the habit of sending him has inexplicably ceased coming, he is reduced to such straits that he has been obliged to pawn some of his possessions and is deeply in debt. He decides to murder Alena Ivanovna, a disreputable old woman who lends money on pledges and is reputed to be very rich. He argues that if great conquerors like Napoleon and Alexander the Great, who had won fame and glory by their colossal crimes, were justified by their successes, it would not be wrong for him to rid the world of a hard and evil usurer, and then, by taking the thousands of rubles which he should find in her possession, to pursue his career without the sordid cares that are blocking his way. He takes a hatchet, which he fastens by a loop to the inside of his cloak, and wrapping up a chip and a piece of iron as a pretended pledge, he goes to her apartment.

Everything favors the accomplishment of his scheme. He finds the suspicious old woman alone, and while she is untying the knot around the package, he strikes her on the head and kills her. Hastily ransacking the inner room, he fails to find the great sums of money which are hidden about, but picks up a few pieces of jewelry and a pocketbook stuffed with bank notes. While he is at work, the old woman's half sister enters the outer room. He strikes her down also, and then, hearing steps, he for the first time thinks to bolt the door. Some persons try to enter. They ring and knock, and suspecting something is wrong, go to find the janitor. Raskolnikov manages to escape. In order not to meet the two visitors coming back with the janitor, he steps into a room just vacated by two painters and there accidentally drops one of the jewel cases. Undetected, he leaves the house. Reaching his room he regards his booty, insignificant as it is, with a sort of horror. He goes to a deserted house and buries it all under a large stone. Returning to his room he discovers blood on his boots and on his clothing. He tries to get rid of all such incriminating evidence. He cannot, however, eliminate his conscience. His

crime haunts him day and night. He becomes ill, and his friends cannot understand his actions, which are those of a crazy man. He is constantly impelled to visit the police station and to revisit the scene of his crime. He is as yet safe from suspicion, since one of the two painters, who had left the apartment house just about the time of the murder, has confessed to being the perpetrator. The inspector of police, who has read Raskolnikov's article, now published, and has a high idea of the young man's abilities, has gathered from his wild talk that he is the criminal. He advises him to confess and bear his punishment like a man; he intimates that his sentence will be mitigated by such action. In the meantime Raskolnikov has confessed his crime to Sonya, a girl of the town, the victim of cruel circumstances. He had met her through a chance acquaintance with her father, an official degraded by drink, and had become greatly interested in her. Raskolnikov finally yields to Sonya's earnest entreaties, goes to the police station and is sentenced to eight years of hard labor in Siberia. The young girl accompanies him, and by her utter devotion brings him back to sanity and complete repentance.

There are subordinate threads of plot, involving Raskolnikov's mother and sister and a wealthy roué named Svidrigailov, who in spite of his rascalities has the saving grace of a generous spirit: he is a character worthy of Dickens. The episode of his suicide is depicted with startling power. So is the tragic end of Sonya's father. The scene of his funeral reaches the highest degree of pathos, mingled with a touch of sardonic humor. One of the most famous episodes in the story shows Sonya reading the New Testament to her unhappy friend: the prostitute and the murderer make a picture which haunts the memory with its realism and its dramatic poetry.

The power of the novel consists in its exhaustive analysis of the motives and reactions of a man who is on the verge of insanity and yet who is shown to be responsible for his deeds. Dostoyevsky had in his own life made a firsthand acquaintance with the lives of the poorest and most degraded people. He understood, as few have, their trials and temptations, and he deploys before the reader a remarkable series of scenes in a style evidently greatly influenced by Charles Dickens as well as by Nicolai Vasilievich Gogol, "the father of Russian realism." The descriptions of the murder, of the meeting of Raskolnikov and Marmeladov at the low *traktir* where the drunkard tells his life story, of the funeral dinner given by Marmeladov's widow and of the life of the exiles in Siberia, which Dostoyevsky knew at firsthand—all these and many more are executed with a masterly pen. The beautiful and touching epilogue wherein Raskolnikov comes to himself lifts the tale from a wholly sordid, depressing, gloomy, and pessimistic tragedy into the serene light of optimism: it fully compensates for the long pages of hypochondriacal psychological analysis, which however microscopic and scientific are yet morbid and unwholesome.

Immediately after the book's publication, a murder was committed by a student at Moscow in almost precisely the same way as that described by Dostoyevsky. He himself remarked that he seemed "to be like a criminal who had committed some terrible deed that weighed on his conscience." The book was anonymously translated into English from the French version and pub-

lished in London in 1885, and in New York the following year. It forms the third volume of the complete works of Fyodor Dostoyevsky, translated from the Russian by Constance Garnett.

CRIMEA, krī-mē'a (Russ. КРИМ), the Crimean Region (or oblast) of the Russian Soviet Federated Socialist Republic of the Union of Soviet Socialist Republics. The Crimea is a peninsula on the northern shore of the Black Sea. It is washed on the west and south by the Black Sea, on the east by the Kerch Strait (which separates it from the Caucasus), and on the northeast by the Sea of Azov. The peninsula is connected with the Ukrainian mainland by the narrow Perekop Isthmus, which is little more than three miles across at its narrowest point. The peninsula has a maximum length of 200 miles east to west, a breadth of 130 miles north to south, and a total area of 10,036 square miles.

The Crimea is divided into three distinct geographic zones. The northern four fifths of the peninsula is a semiarid treeless steppe, similar to the south Ukrainian steppe, of which it is a continuation. This Crimean steppe specializes in the growing of high quality, quick-ripening grain. Other main crops are tobacco, fruit, and cotton. Sheep are the chief livestock, though in general livestock raising is a secondary occupation. Most agriculture in the steppe area is conducted by collective farms.

Below the steppe, and stretching from west to east across the southern Crimea, are the low, wooded Crimean Mountains, a westward continuation of the Greater Caucasian range, which constitute a climatic barrier. To the north, the steppe has the typical continental climate of European USSR, with cold winters and hot summers. Below the mountains is the third Crimean geographic zone, the Russian Riviera, a narrow seacoast lowland two to six miles wide, with a Mediterranean climate of warm winters and dry summers. Because of this climate, and its beautiful scenic contrast of sea and mountains, the lowland is called the all-USSR resort. Here are located innumerable sanatoria and rest homes (many of which were former palaces of the czarist nobility). Both the mountain valleys and the coastal lowland grow large crops of fruit, tobacco, and grapes, partly for export, and partly for shipment to other regions of the USSR. State farms are the main form of agricultural organization. Fisheries extend along the Crimean coasts, particularly in the Sea of Azov, the Kerch Strait, and on the Russian Riviera.

Crimean industry consists mainly of food-processing plants, especially tobacco factories, wineries, and canneries for vegetables, fruit, and fish. Here are produced the best tobacco and wine in the USSR. However, there is also a sizeable heavy industry. Marble and other building materials are mined in the mountains, and salt is extracted from the Sivash marsh along the Azov coast. The Kerch Peninsula (east tip of the Crimea) has some of the largest iron ore and natural gas deposits of the entire USSR. As yet, the natural gas has been little exploited, but the iron ore (reserves estimated at 2,726,000,000 metric tons, with average iron content

of 35 per cent) is mined extensively at the Kamysh-Burun mines near Kerch. Part of the ore is smelted into iron and steel at the metallurgical plant in Kerch, and part is shipped across the Sea of Azov to the Ukrainian port of Zhdanov (the former Mariupol) for processing.

The Crimea exports to other regions of the USSR, iron, steel, iron ore, wine, tobacco, canned vegetables, fruit, and fish. The main imports from other Soviet regions are: coal from the Donets Basin; petroleum from the Caucasus; timber from the Caucasus and Belorussia; textiles from the Moscow and Ivanovo regions; and butter from north European Russia.

The Crimea has often been called a "mosaic of races," because at one time or another various ethnic groups have controlled the peninsula wholly or in part, and their descendants still live in the area. However, today the great majority of the population consists of Russians and Ukrainians. The Crimean Tatars, who ruled the peninsula for many centuries, now live mainly in the mountains. The population is highly urbanized, over 50 per cent living in cities. This is due not so much to industrialization, as to the many seaports and resorts. The chief cities of the Crimea are Simferopol, the capital (pop. 1939, 142,678); Sevastopol, a naval shipbuilding center and the main Soviet naval base on the Black Sea (pop. 1939, 111,946); Kerch, a large fishing port and metallurgical center (pop. 1939, 104,471); Feodosiya (Theodosia), a resort, fisheries center, and grain export port (pop. 1926, 28,656); and Yalta, the largest resort (pop. 1926, 28,838). The total Crimean population (1950 est.) is 1,200,000.

History.—The history of the Crimea extends over 24 centuries. In ancient times, Greek seamen founded trading posts on the coast, one of which, Feodosiya, still bears its original Greek name. When Greece was conquered by the Roman Empire, the Crimean settlements fell under Roman rule. As Rome declined, the Crimean ports transferred their allegiance to Byzantium. From the 7th to the 10th centuries, the entire Crimea was ruled by the Khazars, a race similar to the Armenians and Georgians, but Jewish in religion. A civilized people, the Khazars founded small towns, and conducted a large sea trade. By the end of the 10th century, their power was broken by attacking Russians in the north, and the Asian Pechenegs in the south. The Pechenegs, after ruling the Crimea for a century and a half, yielded to another Asian race, the Polovtsi. These in turn were overthrown in the 13th century by the Mongols, the so-called Golden Horde, who incorporated the Crimea in the Mongol Empire. As this empire disintegrated, the Crimea became part of the Mongol realm in Russia.

Meanwhile, Genoese traders founded settlements along the coast. As the Mongol Empire declined before Russian attacks in the late 15th century, the Crimean Tatars (Mongols) declared themselves independent, although the Turkish sultan in 1475 claimed suzerainty over the Crimea. By the 16th century, the Crimea was the only Tatar state left in European Russia. The Crimean Tatars continually fought the Russian czars, even capturing and burning Moscow in 1571. During the next two centuries, the Tatars, both as a semi-independent nation and as Turkish vassals, were a constant thorn in Russia's side. Russian armies, invading the Crimea in the late 17th and early 18th centuries, were

repulsed; and in 1768, the Tatars again invaded Russia. Finally, a peace treaty between Russia and Turkey in 1774 declared the Crimea independent. Soon afterwards, however, in 1783, the Crimea at its own request was annexed to Russia.

In the mid-19th century, the Crimea played a major role in European politics as the main battleground of the Crimean War. After the Bolshevik Revolution in Russia in 1917, the peninsula became the headquarters of White armies fighting the Communists in the Russian civil war. In 1920 the Communist Gen. Frunze reconquered the Crimea in a spectacular campaign still celebrated in the USSR. The Crimea won fame again in World War II, when its naval base Sevastopol withstood a seven months' siege before surrendering to the Wehrmacht. Late in the war (1944), Crimea's Yalta was the site of the famed conference of President Roosevelt, Prime Minister Churchill, and Premier Stalin. The Crimean Tatars betrayed the region to the Germans in wartime, with the result that their autonomous republic was abolished. CRIMEAN WAR, The. After Russia's annexation of the Crimea (q.v.) in 1783, it was generally believed by the Western powers of Europe that Russia aimed at the dismemberment of the Ottoman Empire and the conquest of Constantinople (now Istanbul) itself. The Greek insurrection of 1821 had brought the rivalry between Russia and Turkey to a head, and war broke out. The defeat of the Turkish Army led to the Treaty of Adrianople in 1829, which gave Russia some slight gains in territory, but, more important, opened the Dardanelles to the passage of her merchant ships. The Western powers did not interfere at this time, but together with Russia, exerted their influence to win Greece's independence from Turkey in 1832. Russia again forced on Turkey a treaty which not only gave her control of the straits, but established a virtual Russian protectorate over the sultan.

Russian diplomats tried unsuccessfully to win the approval of Great Britain for these gains. England's policy, dictated by the need to protect her Eastern possessions, was the preservation of the Ottoman Empire and the containment of Russia's ambitions. Among other indications of Russia's aggressive tendencies was the great naval arsenal of Sevastopol, occupying the most commanding position in the Black Sea at the extremity of the Crimean Peninsula. Begun by Catherine II in 1786, it was provided to an unlimited extent with all the means then developed for both offensive and defensive warfare. Obviously, it presented a serious menace to Turkey. Emperor Nicholas I, one of the ablest and most ambitious of the czars, satisfied himself that the time to strike was at hand. Russia's aim to destroy the Ottoman Empire was the underlying cause of the Crimean War, and the opportunity presented itself in 1852.

The Sublime Porte (as the Ottoman Empire was called), adjudicating a dispute in February 1852 between the Latin and Greek churches in the empire—the former under the protection of France, the latter of Russia—gave a decision concerning the holy places in Palestine, which was considered favorable to Russia. In November 1852 a new demand was made by Russia based on the Treaty of Kuchuk Kainarji (1774), claiming a protectorate over the Greek Church throughout the Ottoman Empire. After complicated negotiations, the Porte, under pressure from France, reversed its former decision and took the side of the Latins, and on December 22 delivered the key of the church of Bethlehem to the Latin patriarch.

The diplomacy of the powers exhausting itself over the dispute, finally, in May 1853, Russia delivered an ultimatum to the Porte. This being rejected, the Russian Army crossed the Pruth and occupied the Danubian Principalities (July 2). On English advice the Porte refrained from regarding this aggression as an act of war, while the diplomats renewed their efforts to find a peace formula. These ended when the Porte, after expiration of an ultimatum, declared war against Russia on Oct. 4, to which Russia responded on November 1 with a like declaration. Meanwhile, European public opinion had become increasingly hostile to the Russian aims. Two days before Russia's declaration of war French and English fleets had entered the Bosphorus. The war opened auspiciously for Turkey with one or two victories over Russian troops by Omar Pasha; but on November 30 a Russian fleet based on Sevastopol destroyed a Turkish squadron off Sinope in the Black Sea. On Jan. 4, 1854 the French and English fleets entered the Black Sea.

Much as the British disliked and feared Napoleon III of France, they felt obliged to form an alliance with France and Turkey, and the treaty of March 12 resulted. England and France declared war on Russia March 28, and three days later the first troops of the Western Allies, a French corps under Gen. F. C. Canrobert, debarked at Gallipoli. By May some 50,000 French troops under Marshal Armand J. L. de St. Arnaud, and 25,000 British under Lord Raglan (Lord Fitzroy James Henry Somerset), were landed there, and later transported to Varna (now Stalin, Bulgaria) on the Black Sea.

The Crimean War has gone down in the records of history as one of the worst managed, badly led, ill supplied, and unnecessarily wasteful of life, of all modern wars. What won it was the courage of the common soldier. The British Army was badly led and inefficiently managed because its leaders were inexperienced in troop command. Lord Raglan, nearly 70, had been on the staff of the duke of Wellington in the Napoleonic Wars; the duke of Cambridge (George William Frederick Charles) had never been in a battle; the earl of Cardigan (J. T. Brudenell) was equally inexperienced in campaigning; the earl of Lucan (G. C. Bingham) was another elderly general. The French marshal, St. Arnaud, a distinguished soldier, died early in the campaign, and was succeeded by General Canrobert, who was also a veteran. Gen. Patrice de MacMahon, too, was an efficient soldier. However, battle after battle was marked by terrible blunders, on both sides. The famous charge of the Light Brigade was only one of these blunders, best known

largely because it was immortalized in verse by Alfred, Lord Tennyson. The armies were conveyed to the battlefield in overcrowded troopships, cholera was rife throughout the campaign: protection, proper food, and equipment were all lacking.

Students of the campaign have pointed out all the mistakes that were made. In the first place, nothing was known of the Crimean Peninsula where the battles were to take place. In September 1854 the combined fleets of Great Britain and France convoyed troopships which transported from Varna the mightiest army ever conveyed by sea, to the west coast of the Crimea, about 30 miles north of Sevastopol. Disembarkation of most of the troops was completed on the 16th, and the allied forces began to move southward on the 19th, the French approaching the banks of the Alma River on the right, the British on the left, early on the 20th. They found the Russian Army occupying a position which Prince A. D. Menshikov, its commander, believed impregnable. A small French force made its way up the cliffs where the river ran into the sea, and surprised Menshikov, but failed to advance. To save the situation, the British were forced to attack from across the river, and scale the heights under direct fire from the Russian guns, suffering terrible casualties in two separate assaults, but finally routing the Russians. Had the Allies followed up this advantage by attacking Sevastopol at once, it is probable they would have succeeded, but in a blunder that was typical of the campaign, they did not pursue the fleeing Russian Army.

Having determined to besiege Sevastopol, the Allies chose the worst plan of attack, making a difficult and costly march over waterless territory to the south of the port, taking no advantage of the fact that it was undefended to the north. The Russians were never cut off from the mainland and their sources of supply. In fact during the siege of Sevastopol the besieged were better off in every way than the besiegers.

These mistakes culminated in the Battle of Balaklava (October 25). Lord Raglan, who was watching the battle from the heights whence he could see the valleys and ridges clearly, sent a vague message to the cavalry commanded by Lord Lucan, who in his position could not see the Russian guns Raglan meant him to attack, but only those at the head of the valley commanding the entire field below. Instead of investigating the situation Lucan gave orders to Lord Cardigan, commanding the Light Brigade, to lead a charge, which his Heavy Brigade would support. Nearly 700 cavalymen charged straight into the Russian guns; only 195 returned.

On November 5 was fought the Battle of Inkerman, in which a powerful Russian assault on the British camp was repulsed. Both England and France at last became alive to the magnitude of the struggle. While the siege of Sevastopol continued, other important positions in the Crimea were occupied, seriously threatening the communications of the Russians and making it possible to destroy some of their supplies. At an early period the Russians, by sinking a number of ships across the mouth of Sevastopol's harbor, had protected themselves from an attack by sea.

On Jan. 2, 1855, Sardinia (Piedmont) under the leadership of Count Camillo Benso di Cavour, formed an alliance with the Allies, and sent a force of 10,000 men under Gen. Alfonso La Marmora to the Crimea. They arrived May 8, 1855.

Canrobert resigned his command after quarreling with Lord Raglan, and was succeeded by A. J. J. Pélissier on May 19.

Sevastopol was finally stormed on June 18, 1855, but this attack failed. Lord Raglan died and was succeeded by Gen. James Simpson. On September 8 the Malakoff tower was stormed by the French under Pélissier, after the British attack on the Redan had failed. General MacMahon, in command of the Zouaves, refused to be driven out of the tower when Russian reinforcements arrived. "*J'y suis, j'y reste!*" was his famous declaration. This assault led to the abandonment by the Russians of Sevastopol. The siege had lasted 11 months.

The Treaty of Paris, concluded on March 30, 1856, guaranteed the independence of the Ottoman Empire and granted her admission to the society (concert) of European powers declared by the other contracting parties: Great Britain, Austria, France, Prussia, Piedmont (Sardinia), and Russia. The Christians in Turkey were to remain under the protection of the sultan, who by a royal order allowed them religious liberty; Russia renounced her protectorate over the Danubian Principalities; the Black Sea was neutralized; the navigation of the Danube was to be free to all nations. The participation of Piedmont was a step toward the unification of Italy later; Austria and Prussia made a defensive alliance against Russia, effectively checking any move she might make west of the Balkans; and Turkey was assured no further attempt would be made by Russia against her territories.

The total casualties in the Crimean War have been estimated at half a million, but out of the sufferings of the men in the Crimean War some good did come. The status and conditions of service for the soldier were bettered; more training for the officers of the British armies was instituted, and later staff colleges were established in Great Britain, on the Continent, and eventually in the United States; commissariat and supply functions of all kinds were improved; and best of all, medical and hospital services were completely reformed. Under the leadership of Florence Nightingale (q.v.), whom the historian G. M. Trevelyan calls "the real hero of the war," army hospitals and army nurses came into existence.

CRIMINAL CONVERSATION is a tort consisting of adulterous intercourse between the defendant and the spouse of the plaintiff. It is similar to alienation of affections, but is distinguishable from it in that the latter may, but does not necessarily, involve adultery (q.v.).

CRIMINAL LAW. Through time, criminal law, like its primitive antecedents, has consisted in whatever complex of institutional patterns existed in a given society for coping with behavior experienced by a significant number of politically significant individuals as seriously threatening to the value system (preferred form

of social order) of the society in question; and the term "criminal" has for many centuries in its various linguistic forms throughout the world been employed to stigmatize persons so experienced.

The element of stigmatization is important to the definition for a variety of reasons: (1) it affords a ritual opportunity for re-affirmation of the preferred value system; (2) it breaks identification with the person in question as an individual, thus affording an opportunity for the venting of aggressions generated in conforming members of the community by the frustrations that their conformity may have engendered; and, (3) it differentiates the low men on the social totem pole from the "madmen," who were recognized, in their more extreme manic and schizophrenic manifestations at least, even in cultures long antedating the development of modern psychiatry, as somehow more tolerable or less dangerous than the criminal. All existing systems of law similarly continue to distinguish between the "insane" (seriously mentally ill or defective) offender and others.

Criminal law today comprises an increasingly vast body of prescriptions promulgated and interpreted by duly constituted authorities in every geopolitical unit of the world, backed by the collective force of the community in question, and governing the infliction of relatively severe negative sanctions on persons whose behavior deviates in a threatening way from the preferred values and institutional patterns. The form and content of criminal law thus differ from community to community, but the common factors are those indicated above. Existing jurisprudential systems differ in terms of their cultural derivations—notably Anglo-North American, Western European, Spanish-South American, Moslem, Hindu, Confucian, and Soviet; and they differ in terms of the amount and degree of counter-mores violence expected.

Where tension is high and the possibility of revolution or counterrevolution is ever present in the calculations of policy makers and administrators, the law tends to be relatively harsh, and the discretionary powers of the military, police, and the prosecuting authorities relatively large and subject to a minimum of judicial supervision. Where tension is low and only common crime as distinguished from revolution or invasion is contemplated, prescriptions tend to be moderated, limited, and subject to stringent judicial supervision.

Criminal law is not, of course, the only branch of modern law dealing with the infliction of negative sanctions. All law ultimately depends on a probability that it will be invoked where relevant situations arise, and that authoritative decisions rendered pursuant thereto will be obeyed or enforced. In this sense the provisions of every known system of criminal law dealing with challenges to authority generally and "contempts" in particular may be regarded as underpinnings of all the other branches of law. Criminal sanctions are also often prescribed as alternative measures in laws setting up schemes of administrative regulation which include as well an array of "civil" and "equitable" measures of enforcement. In such cases the criminal law functions as a secondary sanction.

But the unique feature of criminal law and its primitive antecedents through time has consisted in its institutional function of coping with the

elemental uncivilized threats to local peace and order short of resort to martial rule or individual self-help. Here criminal law operates as a primary sanction. In this respect the historic role of criminal law is analogous to the hoped-for role of a future international law in coping with elemental threats to peace and order on the scale of a world community; and the gradual establishment of "the peace" within local communities, with a corresponding limitation of the permissible use of force and arms, is analogous to the international problem of limiting national resort to force.

What distinguishes the criminal law from other types of regulatory law, and the forms of deviational behavior, which are its primary concern, from those primarily entrusted to other forms of legal or purely social sanctioning? The fact is that there have been many developments in modern law which render the distinction between criminal and certain "preventive" civil proceedings increasingly technical.

Some examples from the United States of sanctions, which are in fact of a severe negative character but technically not classed as "criminal," would include the denaturalization of naturalized citizens found by a civil court to have misrepresented their allegiance, the stigmatizing and exclusion from public employ and participation in various other phases of the life of the community of persons whose loyalty is administratively found to be suspect, proceedings under the antitrust laws wherein such "equitable" relief as dissolution, divorcement, and divestiture is sought by the government, and many others in the licensing field. Under recent legislation in a number of American jurisdictions one may today be committed for an indefinite period to a penal institution or hospital on diagnosis and adjudication as a "psychopathic sex offender"—and this despite the fact that he may thus far have committed no offense for which he could be imprisoned for more than a short term or, under some of the statutes, no offense at all. Such statutes represent an extension of the sort of preventive and welfare concepts on which more familiar procedures such as the civil commitment of the mentally ill or defective, the quarantine of the carriers of contagious diseases, and the juvenile court commitment of delinquent and neglected children, are based.

On a few occasions when American courts detected a punitive purpose in legislative action purporting to be nonpenal, they have overruled the legislatures for failure to conform to the constitutional standards set for criminal prosecution. There was the case of *Wong Wing* in 1896 (163 U.S. 228), wherein the Supreme Court held that a provision in the immigration law that deportable Chinese aliens be imprisoned at hard labor as an incident to deportation was invalid as an attempt to impose an infamous punishment without benefit of the usual criminal procedure for the ascertainment of guilt. There was the *Lovett case* in 1946 (328 U.S. 303), wherein the Supreme Court struck down as a "bill of attainder" a provision in an appropriation act that "no salary or compensation shall be paid" three named employees in the executive branch whose loyalty was questioned in Congress "out of any monies now or hereafter appropriated." The Supreme Court has also recognized that the issue and sanction involved in a civil proceeding may be of such gravity, as in the

Knauer case in 1946 (328 U.S. 654), as to impose on the government an exceptional burden of proof—namely, “clear, unequivocal, and convincing” evidence which does not “leave the issue in doubt.” This was a proceeding to cancel a certificate of naturalization obtained by fraudulent oath and statements of allegiance in 1936 and 1937.

Apart from these technically “civil” proceedings and sanctions, what of the many private groups and organizations which in fact wield more or less unchallenged coercive power over individuals? Some of these are areal in their makeup and some are lateral—that is, not based on or confined to a particular geographical area. Examples of these exist in every country and will readily occur to anyone. Guild socialism and proposals for the corporative state have stemmed in part from recognition of this phenomenon, as have many of the American anti-trust laws.

Where such *de facto* aggregated power is exercised by a private group one may take it that government either tolerates or has failed to break up or to regulate such sanctioning power, since the power to coerce others is supposed to be a monopoly of government, exercised only pursuant to law. Such sanctioning activities are, moreover, social phenomena, as distinguished from the deprivations which one individual acting on his own and using only his own resources may inflict on another. Functionally speaking, and for purposes of cross-cultural comparison, it appears that we need operational criteria for the “criminal” or “penal” as distinguished from the legal and social sanctions unless, like the pure positivist in jurisprudence, we are content with local form and local formal designation.

Primitive Law.—Primitive law, being less differentiated, did not raise these problems. Given a community with a minimum of formal governmental organization, regulations take the form of customs and taboos. Out of these, as they become intellectually rationalized in terms of some more or less articulate philosophy, institutions develop. Formally enacted institutions, as found in contemporary law, are products of high civilization. The earliest known ancient written codes of law (such as those of Lipit-Ishtar and Hammurabi) were rigidly penal in form.

In primitive custom the community as a whole did not greatly concern itself with the redress of private wrongs, injured individuals and their kinsmen being left to get what satisfaction they could through private retaliation. The earliest English form of criminal procedure was simply regulative of the right of summary execution accorded one who caught a wrongdoer on his premises in *flagrante delicto*. A thief was permitted to reclaim his life by paying *wer*, and could take sanctuary in various places such as a church or the demesne of the king, a bishop, or a lord. The idea that wrongdoing might injure not merely an individual victim but also a community as a whole was not grasped until later times. During most of the Saxon period in English history crimes continued to be regarded as acts of war, and blood feuds and private warfare were normal features of society. Community authority and its prescriptions were concerned with reconciliation of antagonists upon established terms rather than with the putting down of violence by legal process. The conception of the “King’s Peace” as a condition opposed

to private war began to gain currency in the time of Alfred (849–899 A.D.).

The foundations of the later English system were early laid, however, by laws ordering the local organization of the country by shires, hundreds, and parishes, for policing purposes. Men were required to combine in associations of 10, each being a surety for the good behavior of the rest, to produce any of the rest charged with an offense or, in the alternative, to make restitution. This was the “frank-pledge.” The hundred courts and county courts corresponded with the local police organization, in criminal matters the sheriff’s “tourn” being the county court held for a particular hundred. Guilt or innocence were originally determined in the county court by compurgation, or by ordeal if the accused was not “oath-worthy.”

Under William the Conqueror (r. 1066–1087) and his immediate successors the supervisory powers of the King’s Court were greatly increased and its concurrent jurisdiction exercised more frequently until the King’s Assizes practically displaced the county court in important criminal jurisdiction. Criminal actions up to the time of Edward I (r. 1272–1307) were instituted by “appeals” to the county courts and proceeded on private initiative rather than action by the crown. In form such an appeal was a wager of combat, each party undertaking to “prove by his body” the justice of his cause. But it was left to the viscount and coroners to determine whether the appellee “ought to have the country,” meaning an inquisition by the judicial committee of the court (precursor of the jury) and a determination of the facts on the oaths or (later) the testimony of witnesses.

Neither the ancient laws decreed by kings nor the earlier acts of legislatures yield much in the way of abstract definitions of crimes. Their provisions typically assume knowledge on the part of officers as to what distinguishes a public offense from a civil trespass. From the forms of appeals given by Henry de Bracton (d. 1268) in his *Leges Anglorum*, it does appear that the idea of a crime being an infraction of public order as well as an invasion of private right had become accepted. The appellant was required to allege that at the time in question he was “in the peace of the lord king,” that the defendant “came with his force against the peace,” in felony and in “premeditated assault.”

Criminal Sanctions Forms.—The forms of criminal sanctions which have been employed at one time or another cover the entire range of ways which might be imagined to punish, incapacitate, deter, or reform culprits. The major forms may be grouped as follows: (a) subjection to open condemnation or ridicule; (b) partial exclusion, permanent or temporary, from participation in the life of the community, as through loss of civil or religious rights, rank, or privileges; (c) deprivation of property, as through fine or forfeiture, seizure, or destruction; (d) infliction of bodily pain; (e) mutilation where pain is incidental to incapacitation or exposure to reprobation; (f) permanent exclusion from the community, as by banishment or exile; (g) imprisonment; and (h) death. Imprisonment (save for pretrial detention) came in late. Mutilation is no longer authorized by most contemporary criminal codes. Torture is universally eschewed in contemporary legal codes, though not altogether eradicated from police practice and war-

time intelligence techniques. The death penalty and any social justification thereof are being increasingly questioned, an impressive number of highly civilized communities having already abolished it with no demonstrable loss of general deterrence.

Substantive Criminal Law.—Substantive criminal law is variously expressed: there are the "code" traditions and the "common law" or "folk law" traditions; and there are the bodies of law supposed to be rigidly construed in accord with the western European "principle of legality" or the Anglo-American principle of "strict construction," and those supposed (like the Nazi and Soviet types) to be subject to the "principle of analogy." But these differences in concept and fashion seem to be reduced through practice and time. The European codes, originally designed as comprehensive and internally coherent expressions of an explicit penal philosophy, have lost much of this character through the accretion of amendments reflecting new orientations and the pressures of new problems, without benefit of continuing periodic over-all revision. The old common law of crime in England and the United States no longer exists, thanks to the accretion of legislation, compilation, and occasional codification.

The important substantive differences between systems of criminal law today, apart from the divergent schemes of values from which they stem, consist in the extent to which they tolerate administrative policing and negative sanctioning of supposed deviates unsupervised by the authorities charged with the administration of the formal or codified criminal law. In this respect the Soviet-type codes appear to be more limited in their coverage than the others—applicable, apparently, only to offenses and offenders not regarded by elite group members as seriously threatening to themselves or the regime.

Criminal Procedure.—Two major systems in criminal procedure compete today—the "inquisitorial" (as exemplified by the 18th and 19th century European codes, and the Soviet-type codes which in this respect are patterned on them), and the "adversary-accusatorial" (as exemplified by the basic Anglo-American common law procedure). They involve different conceptions of the appropriate roles in the criminal proceeding of the defendant and the victim, of the police, of defense counsel and the prosecuting attorney, and of the court.

Inquisitorial Systems.—Under the inquisitorial systems the court and its adjuncts (the examining magistrate and the public prosecutor) exercise full control of the preliminary investigation and of the presentation of the case at trial; the offender, once formally accused, is a central party in the investigation in the sense that he and his counsel are entitled to see all statements of witnesses and exhibits amassed by the police and the examining magistrate, and to suggest further leads to be investigated; the victim is a full party in the sense that he may intervene with counsel as "partie civile" in the pretrial investigation, and at the trial, and have his claims to civil relief arising out of the crime adjudicated in the criminal proceeding; and the court exercises an affirmative rather than umpire role in the conduct of the proceeding.

Adversary-Accusatorial Systems.—Under the accusatorial systems the defendant (and his counsel, if any) are outside the preliminary investiga-

tion, and have little right to any disclosure in advance of the prosecution's evidence; at trial the court functions more as an umpire, leaving the presentation of the official case to the prosecuting attorney and the responsibility of presenting whatever evidence should be presented on behalf of the accused (and the cross-examination of prosecuting witnesses) to the defendant and his counsel. The practice in the United States presents the extreme contrast with other systems in this respect—and here even diverges from the contemporary English. The American system is marked by a minimum of pretrial disclosure of evidence to the accused, and a maximum latitude and obligation imposed on defense counsel to make his own pretrial investigation and himself interview all witnesses.

Trends.—Major global trends in criminal law are fairly clear. In any given geopolitical unit the exceptions to the criminal law's jurisdiction in favor of relatively arbitrary or nonjudicially supervised police measures tend to enlarge or contract depending on rise and fall in the expectation of violence. The preference for coherent systematic codification as against uncompiled and unrationalized accretion of particular statutes and decisions gains ground. The "underdeveloped" or hitherto "low culture" areas of the world are adopting new codes patterned on those of the industrialized or "high culture" nations which happen to be influential in the area in question. There is decreasing resort, where the ordinary run of nonprofessional and situational offenders are concerned, to sentences of imprisonment exceeding five years or involving commitment to maximum security institutions, but an increasing inclination to devise procedures for the early detection of the small "hard core" of chronically antisocial and dangerous (or psychopathic) offenders, and to provide for their indefinite detention in specialized maximum security institutions. The inutility of the local or county jail sentence of a year or less involving primarily idle detention is generally recognized, as is the necessity for productive and vocationally oriented work or other participation in group activities on the part of all persons in custody if they are not to deteriorate.

In the matter of sentencing there is growing recognition that the courts need the help of diagnostic clinics. Probation and parole, like the partially indeterminate rather than fixed sentence, have been assimilated into most contemporary systems, as have special juvenile courts with nonpenal procedures for persons under 16 or 18, and in some cases for youths under 21. Systems of periodic furlough of prisoners classed as minimum security risks are also successfully employed in some of the Latin systems to preserve family ties and to bridge the gap between custody and release on parole.

New and relatively new penal codes of special interest to the comparative scholar include those of Switzerland, Mexico, Yugoslavia, Cyprus, Louisiana, South Korea, the USSR and a number of South American countries. In the realm of procedure, the Federal Rules promulgated by the U.S. Supreme Court in 1946 and those promulgated in New Jersey in 1953 represent the most advanced models in the United States.

GEORGE H. DESSION,

Lines Professor of Law, Yale University Law School.

CRIMINAL SOCIETIES. Criminals, typically, are not social beings. Their tendency is to act alone. Only when circumstances dictate do they acquire partners or join a gang; and, since they are usually undisciplined, maladjusted persons, generally neither the partnership nor the gang membership outlives the temporary necessity which brought it into being. The study therefore of enduring criminal societies, gangs, or other groupings is particularly interesting to the sociologist. However, it must be approached with caution, lest we read into the history of certain organizations which have come to be known as "criminal societies" a wholly criminal motivation, or, on the other hand, confuse gangs of known criminals, assembled briefly under a leader for the commission of a single crime or even for a series of depredations, with the formally organized, well-regulated, truly criminal society. The latter is in most instances racially, nationally, and socially homogeneous, and its activities may extend over a period of several generations, even of several centuries. And we must take care, too, to define "criminal," for, as we shall see, what is "criminal" to one unit of society may well be "patriotism" or "social justice" to another.

The society, fanatically devoted to the achievement of national independence, which attempts to throw off the yoke of the foreign occupier by assassinating his local administrators and terrorizing his transplanted colonists; which finances its revolutionary activities by robbing banks and the payrolls of the invader's commercial enterprises, and which violates openly and contemptuously the laws and regulations of what might be not only the *de facto* but, in the eyes of the world, the *de jure*, government, is a "criminal society" to the occupying government, but a band

of patriots to the people. There is perhaps some relationship between means and end. Does the end justify the means? History makes clear that the use of illegal or criminal means for the attainment of what might be defined as a "good" end has often subtly reshaped or redefined that goal, or diverted the attention and energies of those using the criminal means until the criminality of both means and ends was indistinguishable.

Criminal societies of one type or another have been identified in the history of every people, every nation, and every region. In certain areas they were early brought under control while in other parts of the world they flourished; and in some few localities they are still troublesome. Many of the problems connected with the understanding of these organized flouters of societal regulations may become less difficult if we begin by examining the conditions which seemingly favored the development of criminal societies in the past.

Analysis of the histories of the more prominent criminal societies indicates that the confusions, chaos, social and economic dislocations resulting from wars, and some methods of fighting wars, provide a fertile spawning ground not only for criminality *per se* but specifically for organized crime. Without discussing the sociological and psychological implications of family disorganization, destruction of property, and habituation to violence, it is well established that a number of the criminal associations of past epochs resulted from postwar activities of: (a) guerrilla bands or other irregular troops, organized and supplied by the regular forces, or living off the countryside, but not subjected to the control and discipline of the regular services; (b) underground movements ("fifth column") which behind the enemy lines or within occupied territory clandestinely carried on a harrying warfare; and (c) sea raiders who, under letters of marque and reprisal, preyed upon enemy commerce.

One of the major conditions favoring the growth of criminal societies is foreign occupation or enslavement. Secret societies with national aspirations flourish even when no active revolutionary movement is in existence, criminal methods are employed, and all too often the national aspiration becomes only a cloak for the continuance of a profitable, organized criminality, preying alike on the invader and the native, and giving the independence movement a bad name among the peoples of the world. And since violence often incites counterviolence, secret, terroristic societies of a counterrevolutionary character sometimes spring up in opposition and there ensues a veritable state of war, with outrage countering outrage.

Similar acts of violence can be the response to home tyranny, too, as was clearly evidenced in the Russia of the czars. But even more favorable to the flowering of organized criminal groupings are weak, corrupt, and inefficient governments. All nations have had their criminal societies at one time or another during their national development, but those countries which developed sound governments, placed the administration of justice on a high plane, organized efficient police units, and secured the voluntary cooperation of the people or warred so successfully against criminal gangs as to demonstrate the futility of such activity, rid themselves of this threat to their sovereignty at an early stage in their national evolution. The persistence and power of these societies

in certain other areas can be attributed in large part to intrinsic weaknesses in the governmental structure (for example, disunited Italy), to lack of public morality (wholesale corruption accepted as inevitable), or to inefficiency of the operating arms of the government, particularly the police—due to poor selection and training, low pay, and concealed sympathies with the criminal elements.

No criminal society can long exist without a reserve of popular support and cooperation. Joseph Gollomb, describing the funeral of Nonce Romanetti, the Corsican bandit leader, in 1927, wrote: "Then came mourners on foot, the poor. There were thousands of them. They plodded along with an air of having lost someone dear . . . Some of the women wept. [To the] simple-minded peasantry . . . Romanetti was now a hero, a crusader, a friend of the poor, the terror of the wicked rich." Whence comes this popular support? It is easily understandable in those instances in which the criminality is cloaked by patriotic motives; only somewhat less so when the banditti follow the Robin Hood pattern and divide their loot with the poor and downtrodden of the locality, albeit withholding the major portion. But we have also known instances in 20th century America involving criminal gangs which murdered, looted, and flouted the laws with no pretension to political or philanthropic motivation, yet evoked popular support and sympathy to such an extent that police action against them was inhibited, and their political patrons were continued in or returned to office. The calm acceptance by the people of the city of New York of the oft-demonstrated organized criminality on its waterfront and of the repeated exposures of alliances between its police and organized gambling syndicates, indicates a degree of tolerance of organized criminal activity not found in many civilized communities.

Certain reactions of society to organized groups (political, social, religious), as well as certain types of punishments to individuals, have at times resulted in the formation of criminal societies. Outlawry as a punishment is seldom encountered today, but was frequently employed in the past. A form of outlawry that might be termed societal ostracism is sometimes visited upon peoples and groups which, for one or another reason—not always criminal and not always involving fault—have offended the dominant groups in a community. Thus India at one time drove forth its lepers to live by stealing or other crimes, while various small American communities today banish their ex-convicts and other undesirable citizens, who gravitate to the larger seaport cities and, denied work or status, drift into criminal activities and criminal societies. From 1788 through 1840, the British government sent to penal servitude in Australia some 82,290 convicts—many of them political offenders. Their sentences amounted to slave labor on either private or public works, and brutal treatment drove thousands to escape into the "bush," where they formed gangs specializing in rustling and highway robbery and became known to the public as "bushrangers." They "robbed the rich and helped the poor, and never harmed a lady," and cemented for themselves a solid niche in Australian folklore. It was not until the 1880's that the authorities finally rid the territory of the bushrangers. A similar situation has existed in the areas surrounding other penal colonies, notably the Guianas in South America, where escapees and

expired-sentence men from the French penal settlements often engaged in organized criminality.

The Dutch criminologist W. A. Bongers and the Italian Enrico Ferri have pointed out the relationship between economic conditions and criminality. The persistence of the Robin Hood legend in all parts of the world, the popular support of criminal societies in many areas (or the apathy of the public toward efforts to suppress them), and the personal popularity of the leaders of criminal groups among hardworking, honest, devout people, can be partially explained by the frictions engendered in a society economically so organized that great wealth is ostentatiously displayed by the few against a background of dire poverty among the many. In countries or localities where there is no substantial middle class to fill the role of an ameliorative buffer between rich and poor, the criminal society is apt to flourish, posing as defender of the downtrodden and making a show of equalizing the distribution of property by robbing the rich to give to the poor.

Organized criminality, usually of a minor but irritating nature, has been long ascribed to roving groups such as gypsies, tinkers, and desert nomads. No adequate study of these groups is available. They have been charged with such offenses as begging, fortune-telling, prostitution, gambling, disorderly acts, petty larcenies, and horse stealing, but have rarely been convicted of major crimes involving organized groupings under central direction. Many crimes have been charged to them simply because they are different, foreign, or because, having passed through to another area, they provide a convenient scapegoat for police inability to track down the real criminals.

Categories.—Criminal societies may be treated under five basic categories: (a) communities, tribes, or nations primarily devoted to criminal pursuits, such as the Dacots of India; (b) formal societies, with a name, officers, written or unwritten codes, organized either for criminal purposes, or using criminal methods to attain a non-criminal end, or a patriotic or other noncriminal aim to mask really criminal motivations, as the Mafia of Sicily; (c) informal or casual groupings of persons in the criminal classes occasionally but not always recognizing a common leader and giving obedience to a common but ill-defined code, as the Apaches of Paris; (d) gangs organized for a specific crime or series of crimes which seldom outlive the accomplishment of a limited objective or the death or arrest of the leader; and (e) members of primitive or aboriginal cultures with patterns of conduct not acceptable to civilized peoples, for example, the Moros of the Sulu Archipelago, Philippines, or, better, the headhunters of Africa and South America.

Specific criminal societies may be classifiable under more than one category. Thus the Mau Mau of Kenya are a formal group, nationalistic in aims and terroristic in methods, but representative of a primitive cultural pattern basically at odds with the war-making methods of more "civilized" peoples.

Occasionally, too, examples have been observed of religious fanaticism leading to organized conduct which could only be described as criminality (flagellantes, Skoptsy, etc.)—and in certain historical instances the entire conduct of a legitimate government has been such as to indict it before the bar of world opinion as criminal, for example, Hitler's genocidal campaign against the Jews. It is almost axiomatic that a wholly anarchic

organization could not long exist; hence, within each category will be found conduct restrictions, formal or understood, requiring members to observe certain principles in dealing with other members. At times these intraorganizational laws are more restrictive than those promulgated by society for its own protection. Whether these codes are rigidly observed, or as regularly breached as are society's laws, varies among criminal groups and also within each group from time to time, depending on strength of leadership, outside hostile forces, and other factors.

Origin and History.—The origin and history of the criminal societies of the past are cloaked in antiquity and legend. Indeed, the past records of many present criminal societies have been deliberately obscured to such an extent that few incontrovertible statements may be made concerning these groups. The available sources—legends, folklore, ballads, memoirs of the more literate or exhibitionistic of their members or of the enforcement officers who fought them—do not commend themselves to the historiographer. Nor are court records of much value, the intricacies of the rules of evidence and the code of *omerta* (silence) combining to minimize the amount of testimony relating to the organizations and their operations. Even among members and leaders of existing criminal fraternities there is continuing dispute as to origin, purpose, relationship to other movements, meaning of cabalistic designs and codes, and interpretation of oaths, derivation of names, and translation of argot.

Italy.—The laboratory for the study of criminal societies is the Italian peninsula and its adjacent islands; for it is in that area that they have flowered in greatest numbers, achieved the most spectacular powers, and proved most long-lived. The less well-known societies, the Barabas, the Carbonari, the Tepisti, the Bulli, the Magnaccia, and the Malavita, and to a somewhat lesser extent the maquis-banditti of Corsica, are mentioned occasionally in the literature and until recent times were quite troublesome to the Italian police. Two of Italy's criminal fraternities have, however, more than local fame and merit special study, namely, the Mafia and the Camorra.

Camorra.—The Camorra of Naples has been studied by Cesare Lombroso, Salvatore Ottolenghi, Melville D. Post, and others. It is the most truly criminal among the societies to be examined, having been founded (perhaps by Antonio Giaperelli) in the prisons of early 19th century Naples for the cooperative and systematic robbing of all new prisoners. Ex-convicts on their release organized similar societies to prey on merchants (the protection racket in much the same *modus operandi* as we know it today), to blackmail, and to collect tribute under threat of death from the rich, from other criminals, and even from government officials. For more than fifty years the Camorra scoured the Italian peninsula, centering its activities in Naples, but extending its fangs to the northern cities and to the Adriatic shores. Its chief was the *Macstro*; its recruits were carefully tested and accepted as acolytes only after having proved themselves fitted by at least one assassination; its earnings were divided under a community principle with its two grand divisions, *l'alta* and *la bassa*, sharing unevenly.

After the unification of Italy in the 1870's attempts were made to suppress the Camorra, and much of its strength was sapped by aggressive

governmental action which resulted in the arrest and execution or long prison terms for hundreds of its leaders and members. During the Fascist regime in the 1920's and 1930's new suppressive attempts were made when it was discovered that the Camorra still controlled begging, gambling, prostitution, and organized pilfering from the docks of Naples. Some claim that a *modus vivendi* between the Camorra and the Fascist government was arranged at this time. When the writer of this article was chief of the Allied vice squad in Naples as late as 1944, elements claiming Camorrist affiliation or descent, and using Camorrist signs, were active in all fields of organized crime—although they apparently were not tightly organized, engaged in internecine strife, and did not recognize a common *maestro*.

Mafia.—The Mafia of Sicily is older and more distinguished in its origins and its membership than the Camorra. Ed Reid asserts its name comes from its supposed slogan, *Mazzini autorizza furti, incendi, avvelenamenti* (Mazzini authorizes stealing, burning, poisoning), but Post and others think the name was adopted from a race track near Trapani. The Mafia differs in several respects from the Camorra: it was originally non-criminal; it had strong public support especially in Sicily; its membership numbered many distinguished persons including nobles, army and police officials, priests, and landowners; and at least until 1870 it claimed to be the legitimate, if invisible, government of Sicily. Its chiefs were *bravi* and its members *mafiosi*.

Despite its claims to legitimacy and non-criminal membership, the Mafia's record is red with brutal nonpolitical crimes—thefts, robbery, brigandage, extortion—while its political influence was open to sale. It used dramatic methods to maintain its power among the simple islanders, popularizing the *mano nera* (black hand) as a sign of its vengeance and imposing the code of *omerta* (silence) not only on its members but on all who had any knowledge of its activities.

The use of the *mano nera* has long been common among Corsican, Italian, Sardinian, Montenegrin, and other South European criminals, but this does not mean that American authorities in the 1950's are confronted by branches of this great criminal organization, or that its enrolled members have appeared in all places where the black hand has been used for extortion or other criminal purposes. The fear that the Mafia and Camorra have transferred their activities to the United States and have organized and syndicated crime in the larger American cities is ill-founded. Some Italian criminals have settled in America and in many instances have found it profitable to use Italian criminal methods or symbols in preying on their fellow immigrants or on other groups; but it has never been demonstrated that there is any organizational connection between such immigrant criminals and the Mafia. In many cases native Italians who grew up and committed crimes in the United States, when deported to Sicily or Naples have had to resort to farming or stevedoring to earn a living, as they were not accepted by the organized criminal monopolies in the land of their birth.

France.—France has produced several criminal societies of a still different pattern—the Coquilles, the Nervi, and the Apaches. The first one flourished in medieval France and was seemingly a loose association of all the undesirables of the country (beggars, prostitutes, pickpockets,

thieves) with an internal social hierarchy, a special patois, recognition marks (tattoos and scars), and an unwritten code enforced by murder, branding and maiming. It was with this group that the poet François Villon (q.v.) temporarily allied himself, and it is from their activities that writers through the past several hundred years have found inspiration for opera, fiction, and ballads.

The Nervi of Marseille were identifiable by a small tattoo mark on the outer corner of the left eye. More formally organized and narrower in their specialties than most criminal fraternities in France, they infested the waterfront, controlled thievery of all sorts, and levied tribute on prostitutes. They had no fixed rules, often splintered into warring subgroups, but presented a closed front to the police and the public when any of their members were endangered. As late as 1950 gangs of the Marseille waterfront claimed Nervi membership, but responsible police leaders feel that the organization has died.

The Paris Apaches are not an organized criminal society but rather a loose confederation of individuals and groups engaged in a wide variety of antisocial occupations. Various writers have indicated a degree of internal discipline and control not borne out by the available records. Post, for example, quoting an unnamed commissioner of the Paris police, claims that the king of the Apaches "was a lineal descendant of the old royal family of France, who, in spite of every republican effort, still remained king in a certain circle of Paris." Others have attributed Apache leadership to the fabulous "Monsieur Vidocq," but the most reasonable interpretation of the term "apache" is as a generic name for lawbreakers not unlike the terms "hooligan" or "hoodlum." A small criminal fraternity, specializing in church robberies, though whether from anticlerical or mere profit motivations is unknown, has been identified in northern France under the name of the White Wolves, but little of its history or its organization has been ascertained.

Still other French criminal organizations are encountered in the literature. The *Habits-Noirs* of Paris were probably nothing more than a local Apache gang; but the Thiberts purportedly numbered some 800 criminals functioning smoothly under a single director and engaging in every variety of criminality when they were finally disbanded in the middle of the 19th century. The Lamaire band was a short-lived local gang interesting only because its membership was made up of seemingly harmless folk, respectable men and women, who murdered and robbed under the leadership of one Hippolyte Villet. The Catusse-Menegant, functioning in Paris and other large European cities in the late decades of the 19th century, was led by the notorious Chambon (Victor Chevalier) and was enormously successful in organizing bands of pickpockets, shoplifters, fences, burglars and swindlers. It maintained its own London bank through which it disposed of stolen, swindled, or extorted stocks and bonds and its huge revenues of silver and gold.

The professionalization of policing in France under the leadership of the Sureté and the centralization of criminal investigating have had a restraining effect on the operations of such widespread and powerful criminal societies. But the chaotic economic, social, and governmental conditions growing out of the disasters suffered by France in the two World Wars and the instability

of postwar governments gave impetus to new attempts at organized criminality which, as recently as 1951, caused much concern to those charged with police responsibilities and to the victimized merchants of Paris.

Ireland.—The Rapparees of Ireland flourished for more than 300 years from the 16th through the early 19th centuries. Originally members of the dispossessed clans, brothers and kin to the Wild Geese, they had fought for Ireland through the Elizabethan and Cromwellian wars and had been hopelessly impoverished by the seizure of their estates, while their lives had been made forfeit through ban of outlawry. Organizing their kinsmen and retainers into bands, they took to the hills and bogs and woods of their native districts, and lived adventurously by swooping down on the planters and carrying off their cattle and horses. Their sons and grandsons followed the same lawless life, taking heavy toll of the lives and properties of the English and Scotch usurpers. Popular with the local inhabitants for their attacks on the landlord class and for their division of spoils with the poor, they were sheltered when hard-pressed and warned when danger was ahead. A number of rapparees, violating the usual pattern, resorted to common criminality and victimized the Irish and the invader indiscriminately, until eventually public sympathy turned against them. With the organization of the Royal Irish Constabulary in 1787 and the preoccupation of the anti-British elements with the formal revolutionary movements (Fenian Brotherhood, Young Ireland, and later, Sinn Féin), the rapparee bands were relentlessly tracked down and the "men of the hill" eliminated.

Israel, Kenya.—The Stern Gang in Israel provides an example of the short-lived, formally organized, nationalistic or revolutionary terroristic group which, to the government in power, and indeed to some of its opponents, is a criminal society—but which, because of its noncriminal aim and because of its basic support among a large segment of its people, resists such classification. However, had the Stern Gang continued its existence and operations after the birth of the Republic of Israel and changed the focus of its activity to the private enrichment of its membership, as have so many such groupings in the past, then it would be a truly criminal society.

Nor can we at present categorize as criminal the Mau Mau of the Kikuyu tribe in Kenya, the "Hidden Ones," whose objective is to force the white man to leave Kenya and whose methods include butchery, kidnappings, robberies, and other acts of criminal terrorism—killing livestock, arson, extortion. Perhaps the Mau Mau is merely capitalizing on the social unrest and nationalistic spirit that exists in Kenya and the rest of Africa; perhaps if Kenya's conditions are ameliorated and the Kikuyu reinstated in the lands of their forefathers, the Mau Mau will discontinue its lawless activities; until such time however, despite the obviously criminal pattern it is pursuing in attempting to achieve what may be deemed a patriotic or desirable end, it may not be classed as a criminal society.

China.—A criminal association more nearly in the Mafia-Camorra tradition is the Ching Hung Bong, parent society of the notorious Red and Green Gangs of Shanghai, Hong Kong, Chingwantao and other Chinese cities, and its older and better-known ally the Sam Hop or Chee Kung Tong. The history of these organiza-

tions is hazy—there is some authority for attributing political motivations to their founders, but the record of the past 100-odd years is one of unalloyed criminality. An attempt was made by American and British chauvinist writers during the difficult period in Chinese history at the latter part of the 19th century to confuse the Boxer society with these groups, but no organic relationship and no similarity of aims or methods were established. In the United States their activities centered in San Francisco, Seattle, and Chicago, with smaller groups in New York and other cities. They preyed generally on their fellow Chinese. From 1890 through the early 1920's they engaged in a series of tong wars which brought them unfavorably to the notice of the American police and resulted in the smashing of their organizations. Remnants today are active in narcotics smuggling and sales, illegal entry of Oriental aliens, gambling, and levying tribute on Chinese merchants.

India, North Africa.—India and North Africa provide us with prototypes of whole societies engaged in organized and continuous criminality. The criminal tribes of India—Dacoits, Thuggees (T'Hagi), Kuravers, Boureeah, Oothaegeeras, Sunoreahs, and P'hansigars—engaged in many forms of crime and trained each new generation in the arts and skills perfected by the old. Much of the information we have on these peoples has been written by British military and police officials and is not unbiased. The Indian government recently removed many of the restrictions placed on the movements of these criminal tribes and in the 1950's was engaged in a wholesale rehabilitation movement. It is thought by many that their "criminality" may be somewhat exaggerated and that circumstances of environment, conflict with occidental government and social customs, and primitive or non-civilized concepts of property rights and the inviolability of the human person, may underlie their antisocial behavior. The United States long faced a similar problem in dealing with the Moros of the Sulu Archipelago, and it is of some interest to note that the Philippine Republic itself has not been able to find an easy solution.

Maritime Criminal Societies.—The criminal fraternities of the sea have furnished the historical romanticists with the material for thousands of stories. From the Mediterranean pirates of Caesar's time, through the freebooting brotherhood of the coast, the Cornwall pirates of Merrie England, the Vitalienbruder of north German waters, the Barbary rovers of North Africa, down to the relatively recent exploits of the Caribbean gentry and the ever-present threat of pirate-boarding which still faces smaller vessels in Asiatic waters, we discover similar patterns.

Pirates stem from three sources: (1) private merchant seamen to whom letters of marque and reprisal or similar authorizations were granted in time of war to prey on enemy commerce and who, when the war was over, reluctant to return to more prosaic and less profitable peacetime cargo-carrying, raised the Jolly Roger and continued looting the vessels of all nations; (2) mutinous crews, faced with the automatic death penalty if they returned to their home country and subjected to harassment in the major ports when they attempted to carry on a legitimate commerce; and (3) slave carriers and other criminals of the sea not averse to engaging in piracy when profitable occasions arose.

That any "brotherhood" existed among this motley cabal is pure romanticizing. Whenever opportunity presented they fought with and murdered each other for pirated cargoes, as readily as they attacked innocent merchantmen. They knew no king, no code, and no law—save the law of the knife. Brutal and sadistic in their treatment of captives; avaricious and suspicious in their business dealings; crafty and cowardly but vengeful, their own testimony and the testimony of those who miraculously escaped from their clutches belie the romantic fictions of the tellers of adventure yarns. The persistent efforts of regular naval forces—chiefly British, French, and American—throughout the 19th and early 20th centuries virtually ended their depredations, although in the mid-20th century sporadic piracy on the China coast still remains a matter of lively concern to ship owners.

United States.—The United States has had much experience with criminal societies. The migration of Italian and Chinese crime organization patterns to American shores has already been touched upon. Some attention can profitably be given to those societies without foreign roots or prototypes which have over the past two hundred years presented varying degrees of difficulty to American police organizations.

The United States was and is a pioneer country, peopled for the most part with immigrants and the descendants of immigrants, many of whom were maladjusted to the society of the home country and resentful of restrictions imposed on them there. The 17th and 18th century immigrants arriving in North America found a seemingly limitless land with law and order and restrictions confined to a relatively narrow strip along the Atlantic coast. Those resenting such restriction could journey westward where, like east of Suez, there were "no ten commandments and a man could raise a thirst." Among those who pioneered the American west in the early and mid-19th century and who built up an American tradition of individual freedom of action, resistance to restriction, and antipathy to police, were many who joined in criminal associations preying on Indians, colonists, wagon trains, and even government outposts. The gold rush pilgrims en route to California and the gold trains returning to the East were alike victims (incidentally those who sought to escape this and other hazards by crossing the Isthmus of Panama were attacked by similar groups known as "derienni"); the pony express, the stagecoach, the herd of cattle, the stock of furs, nothing was safe from these desperadoes, some of them allied with Indians, some posing as Indians, some actually in the service of the United States as scouts, or agents, and even as marshals.

After the American Revolution, the War of 1812, and the Mexican War (1846-1848), such bands grew with discharged, disgruntled soldiers. But it was not until after the Civil War (1861-1865) that this form of organized criminality became so widespread as to threaten the future development of the western regions. Organized gangs became so bold that no bank, railroad, or business place even in the relatively thickly settled states of Ohio and Illinois was safe. Guerrillas had been used freely by both North and South in the war; many a soldier returned to find farm, home, and family destroyed; provisions for the orderly re-entry of veterans to civilian life with governmental assistance to those who needed it

had not been made; and the emotions roused by the war had not been assuaged by the assassination of Lincoln and the brutal "reconstruction" of the South by the runaway "Black" Republicans. Hundreds of former riders in Quantrill's guerrillas and other irregular forces swelled the ranks of outlaw bands, provided sensational headlines in the Eastern press, and evoked popular hero-worship of a number of the desperadoes.

With the organization of the Western territories into states, the setting up of public and private law enforcement agencies, and the maturing of the post-Civil War generation, these outlaw bands began to disintegrate and die. Usually the arrest and execution of the leader sent the followers into hiding or forced them to break up and either join the dwindling number of gangs still active or seek an honest, though less adventurous, livelihood. The names of the James and Dalton bands have been written indelibly on the history of the West of this period.

Not so casually, however, can be treated the Ku Klux Klan and the Molly Maguires (qq.v.), contemporaries of the post-Civil War desperadoes. The Klan, organized originally about 1865-1866 to offset some of the ill effects of the Reconstruction program of the punishment-minded men who controlled Congress and to insure white supremacy in the South, was disbanded in 1869, although sporadic violence against Negroes continued for some years. From the early 1870's until 1915 local groups, often using Klan regalia, methods, and name, terrorized Negroes, Catholics, Jews, aliens, and labor organizers, particularly in the Carolinas, Georgia, Mississippi, Alabama, and Tennessee.

In 1915, these scattered groups and new units in many states not of the Old South organized a new and militant Ku Klux Klan, vicious in its methods and powerful enough to control the political machinery of several states and many counties, towns, and villages. With intermittent setbacks, it has pursued its criminal career and it is still, though usually thought dormant, sufficiently dangerous to be on the list of subversive organizations issued by the attorney general of the United States; and has been all too recently (1952 in Florida) responsible for outrages and invasions of civil liberties in many areas of the country.

The Molly Maguires were a small group, racially homogeneous, and related perhaps to the Irish Republican Brotherhood, who rose briefly and terribly to prominence in the coalfields of Pennsylvania in the 1870's. Here the Irish anthracite miners were bossed principally by English and Scotch supervisors; coal mining was a dangerous, ill-paid, man-killing work; there was no union; and all sorts of practices had been introduced to mulct the worker of his day's pay. The Irish miners organized into a secret society about 1865 principally to combat brutality by their overseers, and launched an unprecedented campaign of killings, beatings, and destruction of property. For more than a decade they terrorized the mine fields, but their power was destroyed through the spying activity of a fellow Irishman, James McParlan, who had been employed by the Pinkertons on behalf of the mining companies. Mass arrests were made in 1877 and 20 were hanged.

Worthy of note is the imitation of adult crime organization patterns by juvenile gangs, usually of a transient character but occasionally self-

perpetuating. War-ravaged countries usually spawn such wolf-packs and our own depression period in the 1930's presented a major police problem in the "wild boys (and girls) of the road." In our larger cities, and occasionally in some rural areas, juvenile hoodlums, sometimes allied loosely with adult criminal gangs, but at other times operating independently, have proved dangerous to life and property, and troublesome to law enforcement agencies.

Modern crime in the United States is organized crime only in the larger outlines of those criminal occupations which of necessity require such organization. Thus burglars, robbers, murderers, and rapists are not organized, but there are large and powerful syndicates controlling gambling, the narcotics traffic, and various forms of extortion and thievery. Some of these syndicates are loose nationwide confederations, others purely local. Often they are allied with public officials and with the police; they are occasionally found working hand-in-glove with both political parties and with labor unions (for example, the exposure in 1952 of the intricate working relationships between the International Longshoreman's Association and the dock racketeers in New York City); and often they have a degree of public acceptance or public support that would be shocking if not further analyzed.

The pro-desperado, anti-authority orientation of the American people already adverted to was maximized during the period of the 18th Amendment and Volstead Act (Prohibition) from 1920 to 1933. The gangsters who defied authority to bring whiskey, wine, and beer to a thirsty populace, and the police and politicians who protected them and shared their profits, were accepted in the best circles, envied by some of the law-abiding, and hero-worshiped by many youngsters. A similar situation exists in the field of organized gambling—the law-abiding citizen who wishes to make a small bet and cannot go to the track to do so legally is not going to rise in wrath against the organized criminal combine which makes it possible for him to make his wager illegally at his corner bookmaker. That the Prohibition gangsters murdered and engaged in other forms of crime, and that the gambling syndicates use their profits to finance other, less acceptable, criminal activities has not diminished their social standing among those who demand the services they perform.

The level of criminal tolerance is higher in certain areas of the United States than in any other part of the civilized world; the power of organized criminal societies in some of its larger cities is fantastic; the ineffectiveness of the police is due in part to poor organization, poor recruitment and poor training, but in greater measure to the lack of public support for enforcement of ill-considered laws which a large segment of the public opposes.

The suppression of organized criminal societies solely by police action is impossible, as has been abundantly demonstrated in country after country. Law enforcement and intelligence agencies have achieved some success by infiltrating police officers into the various groups, often at the cost of an officer's life, to observe and report on organization, activities, identity of leaders, and future plans. Again, the police have successfully employed informers and occasionally obtained enough evidence by intensive questioning, or "grilling," of arrested gangsters. But usually the

lower echelon members have little real knowledge of the far-flung activities of the society or of its real leadership.

The cowardly allegiance of businessmen and politicians to these groups, and their failure to report extortion threats and other criminality, handicap the police. It has been suggested that a law making it a punishable offense to pay tribute to an organized criminal group without reporting to the police would have a salutary effect on at least one phase of their operations.

The folklore and public stereotypes surrounding these criminal groups—that they are ubiquitous and omnipresent, that their vengeance carries over into the beyond, that they are as skillful as they are sinister, and that they are the friends of the poor and helpless—aids them in maintaining the law of *omerta* as far as their activities are concerned. It is common knowledge in American law enforcement circles that these criminal societies often take credit both for crimes and philanthropies with which they have had no connection, in order to maintain these fictions concerning their real activities and real purposes. Only an aroused and cooperative public, supporting an efficient police unit, can eliminate them.

DONAL E. J. MACNAMARA,
Assistant Director, New York Institute of Criminology.

CRIMINOLOGY is a part of the branch of sociology called social control. The penal treatment of the criminal is the most drastic form of social repression. Punitive law takes its place alongside custom, public opinion, moral principles, religious beliefs, magical ideas, and many other forms of social control. The acts penalized by law vary greatly from time to time and from place to place. But, at all times and everywhere, there exists some sort of social organization wherein the law prohibits those acts which menace it. A crime may be defined, therefore, as an act which the law forbids and punishes; which is almost always immoral according to the prevailing ethical standard; which is usually harmful to society as organized at a given time and place; and whose repression is, in the long run, necessary or supposed to be necessary for preservation of the existing social order.

Criminology utilizes data derived from several sciences. Zoology, anthropology, and history contribute to describing the nature, origin, and evolution of crime. Meteorology, geography, demography, and the special social sciences such as economics and politics, aid in analyzing environmental causes of crime. Anatomy, physiology, psychology, and psychiatry furnish facts as well as methods for studying the various traits and the types of criminals. Comparative jurisprudence deals in part with the penal treatment of crime and the criminal. Upon these data are based the six branches of criminological science: (1) the origin and the evolution of crime; (2) criminal sociology; (3) criminal anthropology; (4) criminal psychology; (5) criminal jurisprudence; and (6) penology.

Origin and Evolution.—Crime originated in violations of customs among primitive peoples; its evolution may be traced concurrently with the evolution of the state, government, and law. Criminogenic elements exist in the physical environment, the demographic conditions, and the economic and political organization of society. Criminal traits and types arise from the organic and mental bases of criminality. The distribution of criminals with respect to age and sex requires consideration.

Criminal Sociology.—The ecology of crime is studied in the influence of the physical environment upon criminal conduct. This influence can be detected in some phases more or less directly; in others, only indirectly. The effect of topography and the nature of the soil is considerable but can be measured only indirectly if at all. Influence of climate, season, and weather upon criminal conduct can be studied more directly. This study involves a consideration of the temperature, the variations of heat and cold, the relative length of the days and the nights, the humidity of the atmosphere, the precipitation of rain, and the atmospheric movements in the form of winds. Statistics suggesting certain correlations between these telluric conditions and the extent and character of crime have been accumulated.

All social phenomena are influenced by the density and the distribution of population. Civilization itself could not have come into being until the human population had attained a relatively high degree of density. The concentration of population in villages, towns, and cities is of even greater significance for the study of crime. Urban crime exhibits peculiarities as compared with crime in rural districts. Increase in the density of population creates new conditions in which more regulations are necessary to harmonize the conduct of individuals. This situation becomes especially acute when the population is highly concentrated and congested, as in a large city. A comparative study of urban and rural conditions involves an extensive research into the demographic factors in the causation of crime.

Like every animal species, mankind is engaged in a struggle for existence. This is true both of the human species as a whole and of individual human beings. The human struggle for existence has become in large part an economic struggle; that is to say, a struggle to obtain the commodities needed and desired within a system of production based upon the division of labor and exchange. This struggle, though it becomes more complex and indirect in its character, is no less bitter than among many animal species, and is as all-pervasive. It influences every important

aspect of mankind. It is of special significance with respect to criminal activity, because much of this activity arises directly from the economic struggle, while most of it is conditioned by the economic environment. The criminality of any time and place is conditioned and, to a considerable extent, determined by the existing economic system. Where the methods of production are not highly developed, so that the wealth of the community is limited, the living conditions are likely to encourage crimes against the person. As methods of production become more complex and wealth increases, more crimes against property become possible. To measure the direct and immediate influence of economic forces upon criminality, four methods are used:

(1) Fluctuations in the amount of crime may be correlated with economic changes, such as those which recur in the business cycle and those which arise from technological progress.

(2) The economic crimes or crimes in which economic motives apparently are predominant, may be segregated from the crimes in which the economic factor plays a smaller part.

(3) The economic status of criminals may be studied, taking into account the occupations to which they belong as well as the general distribution of wealth.

(4) Professional criminality, or the criminality of those who make of crime a profession and an occupation, may be studied.

In connection with these methods, various economic phenomena and conditions, such as the extreme variations in the distribution of wealth, the pressure due to poverty inducing criminal acts to avoid starvation or to secure a higher standard of living, unemployment, low wages, mendicancy, vagrancy, and other forms of dependency giving rise to crime, should be considered. In fact, the analysis of the economic factors in the causation of crime is the most extensive and complicated problem in the field of criminology.

The political organization of society is determined in large part by the economic organization. But the form of government and the laws promulgated and enforced have some effect, in turn, on economic and other social conditions. The extent to which these conditions can be influenced by the government—and consequently the extent to which criminal conduct can be attributed to government—depends in part upon the prevailing view of the government's functions. There are many of these theories ranging from the extremely individualistic theories of the *laissez faire* philosophers, through the social welfare theories, to the socialistic theories. A government may give rise to crime because it is ineffectively organized or because, even though well organized, it is inefficiently administered. Its effectiveness depends in large part upon the place and the time in which it exists. A form of government well suited for barbarous people may be most unsuitable for a highly civilized people. Hence, it is impossible to generalize with respect to the form of government. Likewise, the efficiency of the administration will depend partly upon the place and the time. The law has usually been unscientific, because it has not been based upon scientific knowledge as to the causes of crime and the traits of the criminal. This knowledge can be used so as to render much more effective both the suppression and the prevention of crime. Governments usually have

failed to gather and make use of statistics, which are of high value in measuring the effects of the different kinds of penal treatment and in throwing much light upon the causes and the conditions of crime.

While economic and political factors are the most important in the causation of crime, there are other aspects of culture which require study. Among these are religion, art, recreation facilities, the press, and education. The influence of these factors is, in the main, indirect. It requires a complicated technique of investigation not yet elaborated.

Criminal Anthropology.—Apart from the criminogenic factors in the physical and social environment, the principal data of criminology are the traits and the types of the criminals themselves. The organic basis of criminality is in the criminals' anatomical and physiological traits. While theories concerning the "born criminal" and the "instinctive criminal" have been shown to be unsound, some hereditary traits predispose their subjects to certain kinds of criminal conduct. The organic traits and processes are, therefore, of fundamental importance in the causation of criminality. While there is no evidence of a type predestined from birth to become a criminal, there are congenital traits within many individuals, which are likely to give rise to criminal conduct under favorable circumstances.

Criminal Psychology.—The mental basis of criminality is partly in certain types of mental abnormality. Amentia is subnormal cerebral development. Dementia is mental deterioration after the brain has developed. Insanity is a derangement of thinking and of conduct due to a pathological state of the nervous system. A psychosis is a severe mental disorder. Neurosis is a disease of the nerves or nervous system. The major neuroses are epilepsy, neurasthenia, hysteria, and psychasthenia, each of which, under certain conditions and in various ways, may lead to criminal conduct. A person may acquire abnormal habits as a result of certain environmental influences, without having a previous morbid basis. Alcoholism or drug addiction may cause a pathological neural condition, which gives rise to a mental disease.

At all times and places, many criminals are persons who are not well adapted to their social environment, because they cannot adjust themselves to the existing customs and standards of society. Some of these individuals cannot adapt themselves to the existing social order, but may be able to adjust themselves to another kind of society. Other criminals are incapable of adapting themselves to any kind of social system; thus they constitute a universal type of criminal. Many combinations of mental traits lead to lack of adaptability.

There are those who cannot adapt themselves to the existing social regime, for they believe it to be wrong, but who also cannot adapt themselves to any kind of social order. A person may become criminal because of abnormal features in his instinctive make-up. This happens because certain instincts are unusually strong or exceptionally weak. If the pugnacious tendency is abnormally strong; it may lead to acts of violence; or if the parental impulse is weak, it may lead to neglect of offspring. A person may become criminal because of some abnormal features in his affective make-up. If the feelings relating

to reproduction, sex, and allied matters are excessively strong, they may lead to crimes of passion; if they are unusually weak, their subject will lack sympathy and will not be inhibited from inflicting pain upon others. The situation with respect to the intelligence is somewhat different. The intellect has no moral significance in itself. But a strong intelligence is not likely to be associated with these abnormalities of the impulsive and affective traits. It is able to comprehend social standards and their justification. A weak intelligence, on the contrary, is likely to be associated with these affective and impulsive abnormalities and find it difficult to comprehend social standards and their justification. The difference between these criminals and mankind in general is only one of degree. No person can become perfectly adapted to the social system under which he lives. Everyone violates moral, legal, and social conventions to a certain extent, therefore being somewhat abnormal and pathological.

Failure to become entirely adjusted is not caused entirely by individual traits, but may grow out of some social system, none of which can be so delicately organized as to obviate all maladjustment. However, most individuals acquire sufficient knowledge and also develop enough self-control to enable them to associate fairly well with their fellows and to avoid violations of social conventions so flagrant in their nature as to bring upon them severe penalties. The majority of those who commit criminal acts are almost normal. In fact, nearly every person is destined, at one or another time, to commit criminal acts. But the great majority are not caught. Most of those who are caught belong to the occasional and professional criminal classes, which include the majority of the criminal population.

The following classification of criminal types suggests the range from the abnormal to the normal: (1) the criminal ament or feeble-minded criminal; (2) the psychopathic criminal; (3) the professional criminal; (4) the occasional criminal, as the accidental criminal, or the criminal by passion; (5) the evolutive criminal of which the political criminal is an example.

The professional class includes criminals who are not feeble-minded or psychopathic, but who commit crimes repeatedly and support themselves entirely or in part by means of their criminal activities. They range from the "big" expert professionals, who reap large profits from their criminal careers, to the petty offenders, who eke out a precarious existence, but who are too stupid and weak by birth or as a result of their experience to commit more profitable crimes. They vary from those who, though not feeble-minded or psychopathic, possess abnormal or pathological mental traits, which have led them into a criminal career, to those who are normal, but have been led into crime by their training and circumstances. They range from those who have deliberately chosen a criminal career, who are the only ones recognized by some criminologists as professionals, to those who have drifted into it largely through force of circumstances and with little or no choice of their own.

The class of occasional criminals also comprises a considerable variety of criminals. It includes all those who, under the pressure of unusual circumstances, sometimes also abetted by pathological mental traits, commit one or a

very few crimes in the course of a lifetime. However, in this group may be some individuals who eventually will become professional criminals. The accidental criminals are led to commit crimes under peculiar circumstances and almost through no choice of their own. The criminal by passion is not feeble-minded or psychopathic, but may possess a somewhat excitable temperament. Such a person may commit a crime, usually a crime against the person, under the pressure of unusual circumstances and under the influence of the passion aroused by those circumstances. He would not commit a criminal act under any other circumstance.

While in the United States, evolutive crime and the political criminal have been completely ignored, in jurisprudence and penology and generally in criminology, in some European countries they have received more adequate treatment. It is customary to distinguish between common crimes and political crimes. The former are acts contrary to the law, committed in the interest of the criminal himself or of those personally related to him. The latter are acts contrary to the law, committed against an existing government or form of government in the interest of another government or form of government. They include many political assassinations; acts against government committed by rebels in revolts, revolutions, and civil wars; many treasonable acts and acts of espionage; and all warlike acts in time of war. It is the intent and purpose underlying a treasonable and illegal act which determines whether it is a political or a common crime.

There are other illegal acts which are not common crimes and yet are not political in the usual criminological sense. They are committed in accordance with and in defense of human rights and in the course of movements for social and economic changes. Their immediate object usually is to induce far-reaching and fundamental social and economic changes, which thus will affect the form of government. Among these crimes, which are broader than the ordinary political crimes, are offenses in defense of the rights to freedom of thought, belief, speech, and publication; and offenses by conscientious objectors to the payment of taxes or to military service; by workers in strikes and other labor disturbances; by reformers who are trying to effect changes in the relations between the sexes and in other social situations. Common crimes are almost invariably antisocial, while offenses which are directly or indirectly political are usually social in their intent and often beneficial to society in their ultimate effect. The latter are social and evolutive as contrasted with involutive or atavistic common crimes.

Description of the principal criminal types is one of the major problems of criminology. Closely related to it is the question of the size of the criminal population and its distribution among the criminal types. In the criminal population should be included those who, at a given time and place, menace society with antisocial acts which law has forbidden. Among them are feeble-minded and psychopathic criminals; professional criminals; and occasional criminals of the moment, such as those who have committed crimes by accident or by passion, but are not likely to commit any more crimes, cannot be said to menace society, and should not be included in the criminal population.

Criminal Jurisprudence.—This science has been studied by lawyers and political scientists who explore the development as well as the present status of law and the mechanism of judicial procedure. As the law is one of the principal forms of social control, it has great sociological significance. While the sociological study of criminal jurisprudence falls properly within the field of criminology, the study of civil jurisprudence also has some criminological significance.

In the early stages of cultural evolution many acts regarded as injurious were punished by private vengeance, usually with the approval of the community. Most of these acts later became either public or private wrongs under the law. The acts considered as harmful to the whole community became crimes or public wrongs, to be punished under the criminal law; while the acts regarded as harmful only to individuals became torts or private wrongs, to be redressed under the civil law. It usually has been assumed that no moral turpitude is involved in torts. There has always been more or less shifting of wrongs back and forth between the criminal and the civil law, so that an act which is at one time regarded as a private wrong is, at another time, regarded as a public one and vice versa.

After criminal law had come into existence, it became necessary to devise a mechanism for applying it. Two things must be accomplished: to determine that a crime was committed and to ascertain who committed it. Criminal procedure has evolved to perform these functions and is operated through courts and judges. The purpose of a criminal trial is to gather, to examine, and to weigh evidence. Consequently, the larger part of the mechanism of criminal procedure is devoted to this work, which ranks evidence as the subject of central importance in the study of the rules of procedure.

Penology.—Study of the origin and evolution of punishment and of the varying conceptions of penal responsibility is the province of penology. Penology has been concerned with theories as to the sanctions for punishment and as to the basis of penal responsibility. One of the earliest justifications for social control was religious. This justification assumed that penalties must be inflicted for violations of the divine law. The religious sanction for penal treatment is punitive and expiatory in the sense that this treatment is a punishment and a retribution for sin. Later came the moral sanction for punishment, based upon belief in a moral law, which is reparatory and exemplary in the sense that penal treatment repairs, in a measure, the breach which criminal conduct has caused in the moral law. In more modern times, the theory that society must be defended against conduct which is, or is supposed to be, injurious to it has acquired influence. The social sanction for punishment is deterrent and preventive in the sense that penal treatment is for society's protection and improvement, and not to make good an injury, which can be obliterated only in part, if at all.

The theories of penal responsibility have ranged from the theories based upon the free will of the individual, through the theories of partial individual responsibility, to the deterministic theories. In accordance with the theories of free will, it has been the tendency to adjust penal treatment to the nature of the criminal act committed. In recent times, the principle of the

individualization of punishment, according to which the penalty is adjusted to the character of the criminal, has gained much influence. This principle recognizes that the character of the individual is determined in large part by forces external to himself, and that society can be protected more effectively against antisocial conduct by changing the character of the criminal than by punishing his criminal acts. The penalties which have been inflicted should be studied in the light of these varying and, to a certain extent, conflicting theories of penal responsibility and of sanctions for punishment.

Variations in Criminological Concepts.—During the 20th century the realization has grown that the concept of crime and of criminal law has become partially obsolete, and that there should be a transfer of emphasis from theft and other petty economic crimes to the much more dangerous, complicated "white collar" crimes. The concept of property is changing and it is recognized that monopolistic and fraudulent business practices cause vastly more harm than the petty crimes. A German-English criminologist (Hermann Mannheim) said: "In the future, we shall have to get used to the idea that not only protection of property, but also the protection against property falls under the scope of the criminal law." Since World War II, it has been recognized that the warmongering and belligerent acts of public officials, which lead to the supreme catastrophe of war, are criminally responsible to mankind.

Criminology in the United States has not given adequate attention to the past and present concepts of crime and of its treatment other than the Anglo-American concepts. Among them are the Oriental and the Soviet concepts. The latter are the most important for the present and the future owing to the great abbreviation of individual property, which now consists mainly of consumers' goods in Soviet countries, and the vast expansion of socially owned means of production. In the USSR "crime" and "punishment" are now called "socially dangerous act" and "measure of social defense," which reflect these changes. The former is defined as any act against the Soviet system.

Crime as a social phenomenon will continue to change as long as society changes. These changes will be in the nature and extent of crime and in the ways in which society reacts against criminal conduct. New social conditions create new occasions for conflict between individual interests, while obsolete causes of conflict disappear with changing conditions. The increase or decrease of crime depends upon the proportion between new and old causes of crime. The continual shifting of ethical standards will always add new forms of conduct to the list of crimes and, at the same time, will remove other forms of conduct from the penal code. Like other branches of sociology, criminology is subject to a continual variation in its field and to a shift of emphasis in its problems.

(New

and often discontinued entirely, wherefore stocks of goods become depleted. On the return of confidence and the renewal of activity, through the resumption of buying by the public, the manufacturing plants experience difficulty in filling orders and their owners or managers therefore borrow money or cut down their working capital to remodel and extend their plants or to purchase extra equipment or for some other form of fixed asset. Often large sums are invested merely in anticipation of future increase in demand and production, mills and railroads being excellent examples of such preparations for future prosperity. Usually this work is carried too far; the means of production outstrip the demand for goods; the ratio between current assets and liabilities is reduced; and such enterprises, with impaired working capital, are liable to insolvency when trade depression sets in. In order to prevent the disruption of industry through the over-extension of credit there must be some means to safeguard the granting of short time or indefinite credits and an emergency currency that will allow a large portion of these loans to be liquidated safely within the brief period of a panic. The usual safeguards are the credit reports of the mercantile associations, the registry of commercial paper and the demand for audits by certified public accountants. The facilities for quick liquidation have been extended by the Federal Reserve system of banks. See CREDIT; CURRENCY; BANKS AND FINANCE—16. *Federal Reserve System of the U.S.*

Crises have been confined practically to western Europe and to the more advanced American countries. In the United States the most notable crises have been those of 1819, 1837, 1854, 1857, 1873, 1884, 1893, 1907, 1914, 1921, 1930. All nearly coincident with crises occurring in England, the crises of 1837, 1857, 1873, 1930 may be called international in extent. Prior to and during the War of 1812 there had been much wildcat banking and the country was launched on a paper money era, the banks being unable to secure specie sufficient to redeem even a small portion of their paper. In 1814 Congress refused a charter to a proposed national bank and people began to lose faith in banks and to withdraw their money. Banks in the South ceased to redeem their notes and on Aug. 28, 1814 the Philadelphia banks suspended specie payments, followed by others in the North and in Ohio, until every bank in the seaboard states had taken similar action. But by threats and legislation the state and federal governments compelled these banks to resume specie payments which the majority had done by the latter part of 1817. Meanwhile in 1816 Congress had established a bank of the United States to regulate the currency. On the conclusion of the war foreign trade began to revive which required vast sums of money; in 1814, while the blockade was in force, the imports were valued at \$12,965,000 and exports at \$6,927,441, but in 1815 these figures had risen to \$113,041,274 and \$52,557,753 respectively and in 1816 to \$147,103,000 and \$81,920,452. Furthermore, during the blockade, when commerce was practically at a standstill, the merchants transferred their capital to manufacturing establishments and when the lifting of the blockade resulted in a vast influx of foreign made goods, protection was demanded for the industries, resulting in the enactment of a protective tariff in 1816 (amended in 1818). Meanwhile in 1815 a

commercial convention had been concluded with Great Britain, under the terms of which each country was to regulate, as it saw fit, its trade with British North American and West Indian possessions. In retaliation for a supposed discrimination against them in American regulations, the merchants of Nova Scotia and New Brunswick secured the passage of the "Plaster of Paris" Act which prevented the transportation of this article in American vessels to the place of consumption. Great Britain then excluded American ships from the West Indies and as these acts rendered idle 100,000 tons of American shipping the shipping interests were prostrate, all allied trades languished, and thousands of mechanics were thrown out of work. In 1811 steamboats had been introduced on western waters and capital and enterprise turned to the task of opening the West. Owing to the ease with which people could secure paper money from the wildcat banks, there was widespread speculation in lands, the record of public land sales being 270,000 acres in 1813, 1,120,000 in 1815, 2,160,000 in 1817, 5,470,000 in 1819 and 820,000 in 1820. Everyone hastened to plunge into debt, expecting to become rich thereby, but when the banks began to contract their discounts and currency began to be reduced, the debtors were unable to meet their obligations and general bankruptcy followed with its attendant hardships in all circles. There was a general depression in business. Many blamed the tariff but the greatest outcry was against the banks, both state and national, and accordingly there was a wave of antibanking excitement throughout the country. But this soon subsided, the states enacted stay laws, prohibited imprisonment for debts less than certain amounts, passed acts against usury, and conditions became about normal in 1821. The "Panic of 1819," as it was called, was the third economic crisis in the nation's history, preceded by less severe crises in 1785-1788 and 1791. It was followed by a mild depression lasting from 1825 to 1829.

In 1832 President Jackson became convinced that the Bank of the United States was using its funds insidiously and ordered the government funds deposited therein to be withdrawn. Since \$9,891,767 in public money was on deposit, the bank was compelled to curtail its loans and could not use any of the public deposits for the benefit of the commercial community. As a result money became scarce, discounts rose rapidly and in 1833 many business houses failed. Jackson's quarrel with the bank resulted, in 1834, in its failure to secure a renewal of its charter, and its career as a national institution was practically ended. Almost simultaneously the national debt was paid off and the treasury began to have a surplus, wherefore a bill was passed in 1836 providing that all but \$5,000,000 of the money in the treasury on Jan. 1, 1837 should be deposited with the several states in proportion to their representation in Congress, and in order to safeguard the deposits the secretary of the treasury was to select the state banks for depositories. The effect of this distribution of surplus revenue among the states was the formation of new banks with nominal capital and the flooding of the country with paper money. In 1837 there were more than 600 such banks with an aggregate capital of \$291,000,000, of which \$149,000,000 was in circulating notes and \$127,000,000 in deposits, while their total loans and discounts amounted to

\$525,000,000. Wild speculation occurred, especially in land, millions of acres being bought and held for a rise. Prior to 1834 the annual sales of land never exceeded \$4,000,000 but in 1834 the receipts were \$4,887,000, in 1835, \$14,757,000 and in 1836, \$24,800,000. But this consisted not of specie but only of credit on the books of the banks that held government deposits. Early in 1837 the banks began to call their loans, to curtail their accommodations and to increase rates of interest. Owing to the crisis in England specie ceased to be imported, whereupon the price of money rose. To make matters worse the wheat crops of the eastern States had been seriously damaged by a scourge of the Hessian fly, wherefore the price of wheat and flour rose rapidly, until early in 1837 wheat brought \$2.25 per bushel and flour \$12.50 per barrel, which caused several flour riots. Furthermore an abnormally large cotton crop the previous year was accompanied by a proportionate slump in prices and a consequent depreciation in the credit of those connected with the cotton industry. Soon three great cotton firms in New Orleans failed with liabilities of \$2,500,000, to be followed immediately by three New York firms with liabilities of \$9,000,000. By the first week in April the failures in New York numbered 98 with liabilities of over \$60,000,000 and two weeks later they numbered 168. Real estate, and railroad, canal and other stocks depreciated in value and thousands of workmen were deprived of employment. Prior to this time President Jackson had caused the "Specie Circular" to be issued, requiring all public land agents to accept nothing but specie in payment. This compelled the banks to redeem in specie practically their entire circulation, and as the contingency caught them unprepared, on 9 May 1837 they suspended specie payments and not until two years had passed did the last of the banks resume. Before that, however, Congress had enacted a bankruptcy law and the States had passed statutes of limitations and similar measures, so that some order began to appear out of the chaos. The most important result of the suspension was the establishment of the independent treasury system in 1840. Moreover, from 1837 to 1842 the number of banks of the country was reduced by nearly 100, circulation and deposits were cut in two, and the banks in general exercised more caution.

In 1854 came a stringency in the money market and hard times began to press upon the country. Trade was more sluggish than at any time since 1837. Money was hard to obtain and the very best paper sold at 10 and 12 per cent, some going as high as 1½ per cent per month. The export of specie from the country was large. These conditions brought on a panic in Wall street in September 1854 which was followed in November by financial disasters in the West and South and the suspension of many banks and bankers. This monetary panic and the subsequent depression were only a precursor of the panic of 1857. After a few minor failures the Ohio Life Insurance and Trust Company of Cincinnati failed on 24 Aug. 1857 with liabilities of over \$7,000,000. This created a panic in Wall street and many brokers and bankers were unable to meet their obligations. On 25 September the Bank of Pennsylvania at Philadelphia suspended payments, to be followed soon by banks in almost every section

of the country. Early in October the Illinois Central Railroad made an assignment, the New York and Erie Railroad Company protested its notes and the Michigan Central suspended payment on its floating debt. The prices of commodities rapidly declined, factories and workshops suspended and thousand lacked employment. Armies of workingmen, desperate in their fear of starvation and poverty, paraded the streets of cities, rioting occurred in many places, and the militia was called upon to restore order. In 1857 there were in the United States and British provinces 6,022 failures, with liabilities of \$282,335,000, and during the first three months of 1858 there were 1,540 failures, with liabilities of \$31,733,000. The causes of the panic have been attributed to various circumstances, such as the reduction of the tariff, the speculation engendered by the influx of gold from California (which caused the belief to prevail that no undertaking was too stupendous for the fortunate nation to undertake), the enormous extension of railway lines, the expansion of bank loans and circulation, the export of specie, the increased importations of merchandise, and undue extension of credit. During 1858 the depression continued unabated but at the opening of 1859 good times seemed to have returned. The South was prosperous, general crops were bounteous and prices were high, but in June 1859 a killing frost laid low the crops of wheat, grain, potatoes, vegetables and fruit in New York, Pennsylvania, Ohio, Indiana and Illinois. Nevertheless by 1860 another season of prosperity seemed at hand, only to be stifled by the Civil War.

In the spring of 1873 occurred a sharp reversal of previously prosperous business conditions. In anticipation of profits, a speculative spirit had been aroused which produced an overproduction in every branch of industry, a general glut of the market and a ruinous decline in prices. Money gradually became tight, discount rates advanced rapidly, and by September little money could be borrowed at any price. After the downfall of a few smaller concerns, the panic broke forth on 18 September when Jay Cooke & Co., of Philadelphia, suspended, as a result of which stocks slumped on the exchanges and a score of brokerage houses, banks and banking firms were forced to the wall. Suspension of payments occurred first at New York but extended to all the larger cities and continued until 1 November. The panic in the "Street" was of short duration but its effects were apparent in commercial and industrial circles for months, thousands of establishments being handicapped or completely prostrated by the lack of available funds to conduct their business. Between 1873 and 1876 the mercantile failures were \$775,000,000 and the defaults by railways up to 1 Jan 1879 amounted to nearly \$800,000,000. The number of bankruptcies up to 1878 was 10,478, while the depression following the panic was even more fatal to productive industries. Between 1873 and 1879 these failures numbered 47,000 and the money loss was \$1,200,000,000. It is estimated that 3,000,000 men were thrown out of work. The depression extended to many parts of the world.

In 1883-84 another period of panic and depression began. The gigantic speculation in railroads reached its zenith about 1880 and a retrograde movement set in. President A. T.

Hadley in his 'Railroad Transportation,' says that of the 29,000 miles of road constructed in 1880-82 only a third was justified by existing business, another third might be profitable some time in the future, and of the remainder some were built to put money into the hands of the builders as distinct from the owners, some were built to increase the power of existing systems, where they were not needed, and some were built to sell as a blackmailing scheme against other roads. During 1883 there were a few small commercial failures and on 1 Jan. 1884 the New York and New England Railroad went into the hands of a receiver. During 1884 and 1885, 41 railway corporations, holding 19,000 miles of track, were placed under receivership and 37 smaller railroad properties were sold under foreclosure. Moreover in the spring of 1884 a decline in the prices of agricultural products occurred. Owing to a great increase in the world's wheat crops, the price fell below that of 1878, resulting in stagnation of interior trade, because farmers held their produce for more favorable market conditions. Hence railway freight traffic was greatly diminished, thereby reducing railway stock dividends, and consequently investors hesitated to embark in railroad enterprises of great magnitude. In May 1884 came the failure of the National Marine Bank of New York, the president of which was associated with the firm of Grant and Ward, which failed shortly afterward with liabilities of \$17,000,000. Several other banks and banking houses failed, the total liabilities of the wrecked concerns being about \$240,000,000. While the panic centred in New York, there were numerous failures in other cities, 11 national banks and about 130 other banks and private bankers being counted in the list. There was no suspension of specie payment during the panic and this, together with bounteous crops, tended to improve conditions, the general distrust diminished, credit circulation was re-established and the discount rates resumed their normal level.

For some time prior to 1894 the foreign financial situation had been much upset and in 1890 the firm of Baring Brothers of London failed with home liabilities of over \$100,000,000. Consequently English holders of American securities dumped them into our market and gold began to flow toward London; this export of gold was further enhanced by high rates of exchange in foreign financial centres and heavy imports of merchandise in 1891. Early in 1892 conditions changed and owing to our enormous exports of wheat a considerable portion of the gold returned, thus restoring our depleted gold reserve. But for various causes the price of wheat suffered a serious decline, English investors became alarmed at the condition of the United States treasury and currency, and, fearing that we might enact a free coinage silver law, again sold their American securities with the result that, owing to exports of gold, the reserve had fallen to \$114,231,883 in May 1892 and was likely to fall below the legal limit of \$100,000,000. The Secretary of the Treasury then discontinued the payment of debts in gold and began to hoard it, and the year passed without much further financial trouble. But prices and cost of living had been advancing without any compensatory increase in wages. The workmen were in a relatively worse condition than before and struck for higher wages, several

disastrous clashes occurring in 1892, especially at Homestead, Pa., in the Cœur d'Alene mining region of Idaho and in the Erie and Lehigh Valley Railroad Yards at Buffalo. In November 1892 Cleveland was elected President on a platform calling for a parity between gold and silver coins, and creditors feared that the government either could not or would not redeem its legal tender notes in gold coin, there being only \$100,982,410 in the gold reserve when Cleveland assumed office, and barely \$25,000,000 in other forms of money. Hence, according to Lauck, the widespread apprehension as to the fixity of the gold standard of payments, together with general industrial unrest, caused the panic of 1893. On 20 Feb. 1893, before Cleveland assumed office, the Philadelphia and Reading Railway, with \$40,000,000 capital and \$125,000,000 debt, went into bankruptcy; on 5 May came the failure of the National Cordage Company with \$20,000,000 capital and \$10,000,000 liabilities, these failures causing a heavy slump in the stock market. On 26 June the government of British India suspended the free coinage of silver and the price of silver dropped in three days from 82 to 67 cents per ounce. In July the Erie Railroad failed and the Milwaukee Bank suspended, causing runs on banks, particularly in New York. In August the House of Representatives voted to repeal the Sherman Silver Purchase Law, but though this helped to restore confidence, the Senate failed to act until 30 October (Cleveland signing the bill 1 November), when it was too late to stem the tide of disaster. In December 1893 the Comptroller of the Currency announced the failure during the year of 158 national banks, 172 State banks, 177 private banks, 47 savings banks, 13 loan and trust companies and 6 mortgage companies, though a few of these afterward resumed business. In 1894 156 railway companies, operating nearly 39,000 miles of track, were in the hands of receivers, the total capitalization of these companies being about \$2,500,000,000, or one-fourth the railway capitalization of the country. Commercial failures increased from 10,344 in 1892, with liabilities of \$114,000,000, to 15,242 in 1893, with liabilities of \$346,000,000. The problem of the unemployed became acute and relief committees were organized in many cities; numerous demonstrations by the unemployed occurred, the most spectacular being the march to Washington in April 1894 of the "industrial army" under J. S. Coxey to demand help from the government. In the same month 130,000 miners stopped work, followed later by 25,000 more; in June to July occurred the Pullman boycott in Chicago; other strikes took place at New Bedford, Fall River and New York; and in January 1895 the employees of the Brooklyn Electric Railway system went on strike. Agricultural disaster also overtook the country in 1894, a drought ruining the corn crops of Iowa, Kansas and Nebraska, reducing the yield to one-fourth that of 1893. The wheat crops were larger, but so were European wheat crops, and as there was no market either abroad or at home the price of wheat declined to its lowest mark, 49 cents per bushel, and similar declines were experienced in the prices of corn, oats, rye and barley. In August 1894 the Gorman-Wilson Tariff Bill became law, the treasury reserve was kept intact during the next two years by

the sale of gold bonds, and the public began to regain its confidence in the government and the stability of business institutions, which was further enhanced by the election of McKinley in 1896 on a protective platform and by the enactment of the Dingley tariff in 1897.

The crisis of 1907 has been called a "rich man's panic" and the "panic of undigested securities." Under the fostering protection of the high tariffs came the organization of numerous consolidated corporations known as trusts, of which, according to one authority, 225 sprang into existence during 1899 to 1903. An era of prosperity set in but in 1906 the life insurance scandals and the subsequent investigations and legislation tended to throw discredit on some of the business methods in vogue. In spite of these revelations, the year 1906 was the most prosperous the country had known, crops being abundant, wages high, iron and steel production enormous, freight business beyond capacity, dividends earned on non-paying stocks and money plentiful for promoting any kind of speculative enterprise. By the end of the year, however, affairs began to take a downward turn, due in part to the Lawson articles, in part to the prosecution of corporate interests by the Federal government under Roosevelt, in part to instability of the banking and currency system, in part to over-speculation and over-expansion of business enterprises and various other causes, resulting in March 1907 in a general unloading of speculative securities. Values continued to decline, producing a temporary stringency in August 1907, which was followed by the financial crisis of October, when several banking institutions of New York and Brooklyn suspended, to be followed by others in various sections of the country. In spite of the inability of business men to obtain adequate financial accommodations, the number of failures was surprisingly small. The government aided the banks by depositing money, the clearing houses issued certificates, the importations of gold increased and confidence slowly returned, the normal level being reached again late in 1908, though the effects were apparent for a much longer time. There was an acute depression in 1914 which World War I interrupted. Another crisis occurred in 1920-1921 but the world-wide demands for all sorts of commodities to replace war's destruction and the fact that the trades had large reserves to draw upon, prevented the severe shock from tremendously lowered prices which the 1929 crisis produced. The wholesale price-level fell 18-20 per cent on the world market between Oct. 1929 and Oct. 1930 and continued downward in 1931. The crisis was attributed to a whole block of causes, financial as well as political; the complicated political conditions in Europe, South America and China; the shifting of gold holdings among various countries, especially to the Bank of France and the Federal Reserve Banks of the United States; the fall in the silver rate, affecting the purchasing power of one quarter of the world's population; overproduction of raw materials, partly due to good harvests and partly the result of artificial price-fixing; the striking spread of protectionism; the spirit of rampant speculation in the United States. Buyers held back in the expectation of lower prices. Certain countries, particularly France, were disinclined to grant any long credits. It is too soon to pass judg-

ment upon these factors as causes. The business cycle has long been the subject of study by economists and statisticians, yet their causes and prevention are unknown. Psychological factors are believed to be important elements, apparent in over-confidence in one period and vague general fear at another.

CRISFIELD, Md., city in Somerset County; alt 5 feet, on Tangier Sound, Chesapeake Bay; about 100m SE. of Baltimore; on the Pennsylvania Railroad. Oyster and crab fishing, shucking, packing, refrigeration and shipping are the industries, and there is a terrapin pound. Boats are built here. Pop. (1950) 3,688.

CRISIS, in medicine the turning-point in a disease at which a decided change for the better or the worse takes place. In regular fevers the crisis takes place on certain days, which are called critical days (the 7th, 14th and 21st); sometimes, however, a little sooner or later, according to the climate and the constitution of the patient. The word crisis is also figuratively used for a decisive point in any important affair or business, for instance, in politics and commerce. See also **CRISES**, **ECONOMIC**.

CRISIS, The, a novel by Winston Churchill (q.v.), American author, published in 1901.

An historical novel in the idealistic vein, it deals with the turbulent events and sharp issues of the Civil War years in St. Louis, a time when that city was torn between slavery and antislavery sympathies. These are respectively embodied in a typical Southern heroine, the proud and beautiful Virginia Carvel, and Stephen Brice, a highminded Bostonian of good family but limited financial resources. Other characters, who contribute usefully to a conscientious picture of the times, are the heroine's father, a Southern gentleman of the old school; her first cousin, Clarence Colfax, a hot-blooded cavalier; and the cold, acquisitive, caddish carpetbagger from the North, Eliphalet Hopper. The author's own point of view, which appears to be closer to Unionism, than either Abolition or Slavery, is represented by Judge Whipple, an intense admirer of Abraham Lincoln.

The story deals earnestly and discursively with its significant subject. It was very popular when it appeared, and it continues to be read, its attractions, particularly for the young, including a detailed account of Sherman's March to the Sea, and more or less intimate sketches of Lincoln, Stephen A. Douglas, General Grant, and General Sherman.

CRISIS, The, the general name given to a series of political articles by Thomas Paine. These are 13 in number, exclusive of a "Crisis Extraordinary" and a "Supernumerary Crisis." The first and most famous, published in the *Pennsylvania Journal*, Dec. 19, 1776, began with the famous sentence, "These are the times that try men's souls." It was written during the retreat of Washington across the Delaware, and by order of the commander was read to

groups of his dispirited and suffering soldiers. Its opening sentence was adopted as the watchword of the movement on Trenton, a few days after its publication, and is believed to have inspired much of the courage which won that victory." The 13th, published April 19, 1783, bears the title "Thoughts on the Peace, and the Probable Advantages thereof." It opens with the words, "The times that tried men's souls are over." The pamphlets throughout exhibit political acumen and the common sense for which Paine was remarkable.

CRISP, Charles Frederick, American jurist: b. Sheffield, England, Jan. 29, 1845; d. Atlanta, Ga., Oct. 23, 1896. He came to the United States when a child; served in the Confederate Army, 1861 to 1864; was solicitor general of the southwestern judicial circuit of Georgia from 1872 to 1877, and judge of the superior court of that circuit, 1877 to 1882. He resigned to accept a nomination for Congress, of which body he was a member until his death. From 1891 to 1895 he was speaker of the House.

CRISPI, Francesco, frän-chäs'kô krës'pè, Italian statesman: b. Ribera, Sicily, Oct. 4, 1819; d. Naples, Aug. 11, 1901. He studied law at the University of Palermo, receiving his doctorate at 18, and settled in Naples in 1846. He took part in the Sicilian revolt of 1848, but when the Bourbon government was reinstated fled to Piedmont, then to France and England. In London he became acquainted with Giuseppe Mazzini, with whom he conspired for the freedom of Sicily. After the war of 1859 Crispi returned to Italy, set in motion his plans for insurrection, and in 1860 assisted Giuseppe Garibaldi in the expedition of volunteers for the deliverance of the Two Sicilies (q.v.). In July 1887 he became prime minister and earnestly supported the Triple Alliance of Germany, Italy, and Austria. He was overthrown in 1891, but two years later was recalled to the premiership, an office he held until 1896, when he was deposed after Italy's defeat by the Ethiopians at Aduwa. Crispi's greatness is no longer disputed. His vigorous persistence brought Italy among the Great Powers of Europe and gained for that country a new trust and confidence.

CRISPIN, kris'pîn, and **CRISPINIAN, kris'pîn'i-ân**, Saints, Christian martyrs and patron saints of shoemakers and other workers in leather. It is not certain whether they were brothers. According to legend, the two set out as missionaries of the Christian faith and traveled to Soissons in Gaul, where they made many converts while earning a livelihood by shoemaking. Their festival falls on Oct. 25, the day in 286 or 287 on which they were beheaded by order of Emperor Maximian, during Diocletian's persecution of the Christians.

CRISPUS, Gaius Sallustius. See SALLUST.

CRISTOBAL, krīs-tō'bāl (Span. Cristóbal, krës-tō'vāl), town, Panama Canal Zone, at the Atlantic entrance to the Panama Canal. Capital of Cristobal District, it comprises that part of the city of Colón, Panama, lying within the boundaries of the Canal Zone and upon lands purchased by the United States. Pop. (1940) district, 20,325; town, 826.

CRISTOFORI, krês-tô'fô-rê, Bartolommeo Italian harpsichord maker and reputed originator of the piano: b. Padua, Italy, 1655; d. (probably Florence) 1731. After moving to Florence in his early thirties, he invented a hammer action that permitted variations in both soft (*piano*) and loud (*forte*) tones not possible with the existing harpsichord, and thus developed the *pianoforte*, about the year 1710 or 1711. One of two early pianofortes ascribed to Cristofori, dating back to 1720, is now in the Metropolitan Museum of Art, New York City. See also PIANO.

CRITIAS, krish'i-äs; krit'i-äs, Greek orator, poet, and politician: d. 403 B.C. A pupil of Socrates, he applied himself to the study of eloquence, and Cicero cites him among the great public speakers of that day. Banished from Athens about 407 for some cause not known to us, he retired to Thessaly, where he incited an insurrection among the Penestae, or serfs. Subsequently he visited Sparta and wrote a treatise on the laws and institutions of that republic. Returning to Athens with Lysander, 404 B.C., he was appointed one of the famous Thirty Tyrants (q.v.) set by the Spartans to govern Athens. After a cruel and oppressive use of the power thus conferred upon him, he fell in battle against Thrasybulus and his followers. Plato, who was a relation of his, made him one of the interlocutors in his dialogue "Critias, or the Island of Atlantis."

CRITICAL AND HISTORICAL ESSAYS CONTRIBUTED TO THE EDINBURGH REVIEW. See MACAULAY'S ESSAYS; MACAULAY, THOMAS BABINGTON.

CRITICAL POINT or **CRITICAL STATE**, in *metallurgy*, is a point at which the fall or rise of temperature of a metal or alloy that is being cooled or heated is temporarily retarded because of evolution or absorption of heat resulting from a rearrangement of the molecules, or within the molecules, of the metal. For example, at its two upper critical points, about 1400°C. and 910°C., pure iron changes its crystalline form. At its critical point for magnetism, about 770°C., an intermolecular change occurs: above this temperature iron is almost nonmagnetic; below, it is strongly ferromagnetic. Carbon steel has yet another critical point, the "recalcence point" at about 710°C.: steel is a solid solution of carbon in iron above this temperature, but a mixture of cementite (Fe₃C) and ferrite (pure iron) crystals below.

In *physics and physical chemistry*, the term critical point refers to the state of temperature and pressure at which a liquid and its saturated vapor are indistinguishable, the values of their densities and other physical constants being equal. It was long known that gases could be liquefied more easily at low temperatures, and several gases were liquefied by applying pressure while they were chilled by a freezing mixture of ice and calcium chloride. All efforts to liquefy oxygen, nitrogen, and hydrogen failed, which led to the idea that these might be "fixed" gases that could not become liquid. Thomas Andrews, the Irish physicist and chemist, in his Bakerian lecture for 1869 "On the Continuity of the Gaseous and Liquid States of Matter," showed this view to be erroneous. There exists for every gas a definite temperature above which it cannot be

liquefied by application of pressure, but below which a suitable pressure will convert it into the liquid state. The temperature so defined is called the "critical temperature." The vapor tension of the liquefied gas at its critical temperature is called the "critical pressure" of the gas. The volume occupied by a unit mass of the gas or the liquid at its critical temperature and critical pressure is called the "critical volume."

The critical constants of 17 chemical elements and more than 200 compounds have been determined. Recent measurements of critical temperatures are reliable to a few tenths of one degree. The values of critical pressure and especially of critical volume are less precise. The accompanying table gives the values of critical constants of several gases, including isotopes of hydrogen and helium. The critical temperatures are given in degrees centigrade, and the critical pressures in atmospheres.

CRITICAL TEMPERATURES AND PRESSURES

Substance	Critical temperature (centigrade)	Critical pressure (atmosphere)
Sulphur	1040	116
Aniline	425.6	52.3
Water	374.2	218.3
Chloroform	263.4	54
Ethyl alcohol	243	63.0
Sulphur dioxide	157.5	77.8
Methyl chloride	143.1	65.9
Ammonia (NH ₃)	132.3	111.3
Dichlorodifluoromethane	111.5	39.6
Hydrogen sulphide	100.4	88.9
Hydrogen chloride (HCl)	51.4	81.5
Acetylene	36	61.6
Carbon dioxide	31.0	72.9
Methane	— 82.1	45.8
Oxygen	— 118.4	50.1
Argon	— 122	48.0
Air	— 140.7	37.2
Nitrogen	— 147.0	33.5
Neon	— 228.7	26.9
Hydrogen (D ₂)	— 234.9	16.2
Hydrogen (HD)	— 237.3	14.6
Hydrogen (H ₂)	— 240.3	12.7
Helium (He ⁴)	— 267.9	2.26
Helium (He ³)	— 269.8	1.15

The boiling point of a substance is at the critical temperature if the external pressure upon it is equal to the critical pressure. When the pressure is diminished, the substance boils at a lower temperature. Let us, as an example, convert one liter of carbon dioxide gas at 25°C. and 1 atmosphere pressure into a liquid at 25°C. and 150 atmospheres pressure, keeping the temperature constant as we increase the pressure. Condensation begins at about 60 atmospheres, and the pressure cannot be made greater until all the gas has changed to the liquid state. The change of volume as the gas condenses, while both the temperature and the pressure remain constant, is called a discontinuity.

There is a method by which this discontinuity can be avoided. First heat the gas from 25°C. to 50°C., at 1 atmosphere pressure, and then raise the pressure to 150 atmospheres. This can be done without liquefying the gas, for 50°C. is higher than the critical temperature of carbon dioxide. Then lower the temperature to 25°C., keeping the pressure at 150 atmospheres. No abrupt change of condition is observed during this process of cooling at a pressure higher than the critical pressure. Nevertheless, the carbon dioxide is liquid at 25°C. and 150 atmospheres. The substance is converted from the gaseous state into the liquid state in such a manner that the transi-

tion is imperceptible to the senses, and is not accompanied by any sudden change of density.

HOWARD H. MARVIN,
University of Nebraska.

CRITICISM, the act of clarifying, evaluating, and communicating one's responses to a work of art, is a natural and inevitable part of esthetic experience. While it is stimulated by all the arts, its most ancient and powerful manifestations have been literary. Hence "criticism" ordinarily means "literary criticism" and as such has become a major branch of belles-lettres, in some eyes an art in itself. As old as the Greeks (Aristophanes, Plato, Isocrates, Aristotle, Longinus) and their Roman followers (Cicero, Horace, Petronius, Quintilian), criticism has flourished in every age of literary vitality and has become a particularly exciting and rewarding pursuit in 20th century America.

The problems to which criticism addresses itself may be listed as (1) literary theory, that is, essentially psychological questions of the genesis of the creative impulse, its projection into esthetic perceptions or intentions, its technical expression into esthetic form, and the means of its communication to its audience; (2) literary history—the biographies of authors, the histories of literary genres, conventions, taste, and ideas; (3) the careful elucidation and explication of the artistic content of works of literature together with evaluation (whether personal and impressionistic, relativistic—as sociological, political, etc.—or judicial and absolute) of what is finally found. A purist view might insist that only activities under the third group are legitimately "criticism"; but experience has shown that all three are essential.

Though meaningful work in criticism was done during the Middle Ages and the Renaissance, it did not begin to emerge as an important intellectual enterprise until the "classicist" or "neoclassical" age.

Leading critics were Pierre Corneille, Nicolas Boileau-Despréaux, Voltaire (François Marie Arouet), Jean Baptiste Dubos, Denis Diderot in France; John Dryden, Alexander Pope, Joseph Addison, Francis Hutcheson, David Hume, Samuel Johnson, Edmund Burke, Lord Kames (Henry Home), Hugh Blair, and Archibald Alison in England. The Romantic revolt that followed was spearheaded by Johann Gottfried von Herder, the brothers August Wilhelm and Friedrich von Schlegel, and Johann Wolfgang von Goethe in Germany; in England the great names were William Wordsworth and Samuel Taylor Coleridge, William Hazlitt, Charles Lamb, Thomas De Quincey, Lord Byron, Percy Bysshe Shelley, and Thomas Carlyle. The advancing 19th century made criticism increasingly important; John Ruskin, Matthew Arnold, Thomas Babington Macaulay, and John Stuart Mill came forward in England to be followed by Walter Pater, John Addington Symonds, John Morley, and George Saintsbury at the head of an army of critics. Charles Augustin Sainte-Beuve, Ernest Renan, and Hippolyte Adolphe Taine were similarly the giants in France, Francesco De Sanctis and Benedetto Croce in Italy.

Though many earlier American writers worked with literary theory or dabbled in criticism, the first major American critical work was Edgar Allan Poe's theorizing about poetry and the short story. After Poe, Ralph Waldo Emerson, James Russell Lowell, Walt Whitman, William Dean Howells, and Henry James stood out from the growing crowd of critics. But it was in the 20th century that criticism matured in America. While Thomas Ernest Hulme, Ivor A. Richards, Virginia Woolf, William Empson, and Frank Raymond Leavis were writing in England and Charles Maurras, Paul Valéry,

André Gide, Jacques Maritain, André Breton, and Georges Duhamel in France, in loose alliance with some of them, or quite independently, a number of American schools of criticism arose.

Much influenced by Joel Spingarn and his impressionism, a school of aesthetic salvationists and apocalyptic cultural nationalists grew up around the early Van Wyck Brooks and Randolph Bourne. They were met by an equally energetic school of Neo-Humanists, traditionalists, adherents of judicial criticism by ultimate, absolute standards, many of them professors, who rallied to Irving Babbitt, and Paul Elmer More. Meantime two American expatriates, Ezra Pound and, more significantly, T. S. Eliot, reacted partly to the impulses from the American schools and partly to European influences, and laid the groundwork for what eventually was popularized as the New Criticism. Functioning largely through the "little magazines," this movement gathered recruits from many camps and came, in the 1940's, to dominate American criticism. John Crowe Ransom, Cleanth Brooks, R. P. Blackmur, Allen Tate, and Yvor Winters led the New Critics, whose primary effort was to prove the autonomy and power of the aesthetic imagination by painstaking analyses. Their principal opposition before World War II came from the "proletarian" critics. Newton Arvin, Kenneth Burke, James T. Farrell, and Edmund Wilson were foremost in relating literature to wide socio-economic factors on a more or less doctrinaire Marxian basis. Each of these schools has in some sense fulfilled itself, and we may look for new developments in criticism.

EDWIN H. CADY.

CRITIQUE OF PURE REASON, The. *The Critique of Pure Reason (Kritik der reinen Vernunft)* is the most important work of the German philosopher Immanuel Kant (q.v.). It is perhaps the most famous book in modern philosophy, and has exercised much influence ever since its publication in 1781.

One reason for this importance is that, in it, Kant mediated between the two opposed philosophic movements which preceded; the Continental rationalism of René Descartes, Baruch Spinoza and Gottfried Wilhelm von Leibnitz, and the British empiricism of John Locke, George Berkeley, and David Hume. Rationalism had maintained that all knowledge must be based on reason and conception, and that sense perception is a secondary and insufficient ground for real knowledge. It had also claimed knowledge not only of the visible world but of realities beyond sense, such as God and our own immortal souls. In contrast, empiricism had maintained that all knowledge must derive from sense; and Hume

had come to the skeptical conclusion that there can be no theoretically sufficient ground for such knowledge at all.

Kant took the third position that knowledge requires both sense perception and conceptual understanding. Concepts without sense intuitions are empty; and intuitions without concepts are blind. But by bringing intuitions of sense under concepts of the understanding, valid knowledge and science are possible; and there is an answer to Hume's skepticism.

Kant further criticizes the rationalists' claim to know transcendent realities. If knowledge requires sense perception as well as conception, then we cannot know what lies beyond sense. However, he held that we have a rational ground for believing in God, and in our nature as immortal and as free moral agents. (This last point is only outlined in the *Critique of Pure Reason*, full development of it is found in his later-written *Critique of Practical Reason*.)

Perhaps a main reason for the wide influence of the *Critique of Pure Reason* lies in just these facts: that it offers an impressive defense of knowledge and science against skepticism while leaving room for a rational ground of moral and religious convictions, outside the scope of science.

The first half of the book is occupied with the defense and explanation of the possibility of valid knowledge. A main premise for this is Kant's distinction between ultimate realities (things in themselves) and phenomena (things as they appear to human minds). What ultimate reality is like, apart from our capacity to perceive and understand it, we have no means of knowing; and no hypothesis about it can be either proved or disproved. The world we know must be bounded by our limitations of perception and imagination, and our power to grasp conceptually, and what falls within these limits is the world of phenomena. It is this phenomenal world of things as they appear to us, and not the imperceptible ultimate realities, to which knowledge and science are addressed.

But just this limitation of phenomena to what we can apprehend assures us that the world we discover in experience will have certain reliable characteristics. If we can sense only in certain ways, and conceptually understand only in certain ways, then we know *a priori* (with certainty and in advance) that all the phenomena we shall ever encounter in our experience will conform to these modes of our possible apprehension.

The first set of such conditions of possible human experience—the forms of our sense intuition—Kant discusses in the section headed "Transcendental Aesthetic." He points out that we can neither sense nor imagine anything except in the form of the three-way spread of space and of a one-dimensional on-going time. These limitations of our intuition assure, Kant says, the certainty of mathematics. Whatever we can discover by sense must conform to the principles of geometry. And since any collection or array of things we can count, one after another in time, will answer to all the laws of arithmetic, we also know *a priori* that arithmetic principles will hold of anything we can ever find in experience.

In the section headed "Transcendental Analytic," Kant discusses the function of conceptual understanding as setting similar *a priori* conditions of all human experience, and by so doing assuring certain principles which are basic for all physical science. In the first place, all human

experience—in contrast to that of some lowly creature which had sense-feelings but could not think—is characterized by the fact that what drops out of sight still does not drop out of mind. In recognizing any object or grasping any series of events, we synthesize—think together—something retained from past experience along with what is now presented. To see a house, for example, we must think together the four sides of it as being simultaneously there, although we cannot sense them simultaneously but only one after the other. To this general form which all human experience has as a thinking together of past and present, Kant gives the name “the transcendental unity of apperception.” The more specific modes of such synthetic thinking he calls the “categories” or “pure concepts of the understanding.” He offers a list of these categories, derived from the logical modes of judgment. They represent the basic ways in which alone we can think objects and events. For example, if we apprehend what we see as the color of an apple, we are attributing the sensed color to an enduring thing, the apple; and this mode of our thinking is that of “substance and attribute.” But if we observe that a building is now destroyed because of an explosion, we are thinking in the mode of “cause and effect.” That our experience as revealing objects and events reflects these categorical modes of our understanding, has the consequence that all phenomena are necessarily subject to basic principles, such as that every appearance must be an attribute of some substance, and that for every event which happens, there must be some cause on which it follows according to a rule. It is such *a priori* principles which are presupposed by all physical science and make possible the validity of it.

In the section headed “Transcendental Dialectic,” Kant discusses the problematic things which lie beyond sense—“noumena” as he calls them. Our conceptions of them he labels “Ideas of Pure Reason.” As already indicated, he maintains that we can have no knowledge of such transcendent entities; and it is here that he criticizes the rationalistic claims to such knowledge. He recognizes, however, that such ideas inevitably occur to any rational mind; and he seeks to explain why. It is the function of reason to look for ever higher generalizations and more comprehensive concepts. It assumes that there is an explanation of *everything*: that for whatever is given as conditioned, there is the totality of its conditions. But this thought leads to puzzles which Kant calls “antinomies.” For example, what I now observe has a cause—that, my understanding tells me. And the cause of it has its cause, and this in turn has a cause, and so on. But if this series of causes of what I see is infinite, how could all of them have happened already, one after the other? So I think of some absolute beginning in a first cause. But if I think of anything as the first cause, what made it happen when it did? We cannot clearly imagine a complete causal series, either with or without a beginning. So also, we cannot imagine the whole world as either finite or infinite, or the unitary soul as subject of all our experience, or God as the ground of all things.

Though Kant denies any possible knowledge of objects corresponding to such ideas, he nevertheless ascribes to the ideas themselves a valid function, even for science itself. They direct our thought to the desirable progress of our under-

standing in the direction of ever higher generalities and more comprehensive, more detailed, and more connected knowledge; and remind us that the task of science is forever incomplete. This function he calls “the regulative use of the ideas of pure reason.”

The authoritative German text of the *Kritik der reinen Vernunft* is that found in the complete edition of Kant's works, brought out by the Prussian Academy of Natural Science (Berlin and Leipzig, 1902–1922). The best German commentaries are those of Hermann Cohen, Erich Adickes, and Ernst Cassirer. The fully satisfactory translations in English are those of Max Muller (New York 1896) and Norman Kemp Smith (New York 1929). The best commentary in English is that of Norman Kemp Smith. See also ETHICS—Recent Modern; PHILOSOPHY, HISTORY OF.

C. I. LEWIS.

CRITIUS AND NESIOTES, Greek sculptors of the late 5th century B.C. Their most famous work is a group of the tyrannicides Harmodius and Aristogiton which stood on the agora at Athens. A Roman copy exists in Naples, and copies of the heads elsewhere.

CRITO, kri'tō. (1) Athenian philosopher: fl. 400 B.C. He was a wealthy friend and disciple of Socrates, whom he helped financially and whose escape from prison he argued for and vainly planned. In Plato's dialogue bearing Crito's name, Socrates explains his reasons for not trying to escape and accepting death instead.

(2) Athenian poet of the New Comedy: fl. 170 B.C. Of his plays three titles and eight lines remain.

(3) Neo-Pythagorean philosopher: fl. 1st century B.C. or A.D. Of his treatise *On Providence and Good Fortune* only three fragments survive.

(4) Greek physician (full name TRITUS STATILIUS CRITO): fl. 100 A.D. He practiced at Emperor Trajan's court. Large portions of his studies on cosmetics and on drugs are contained in Galen's medical works and some fragments are preserved by other authors.

CRITOLAUS, krit-ō-lā'ūs. (1) Greek philosopher: fl. 2d century B.C. A native of Phaselis in Lycia, he migrated to Athens, Greece, where he became leader of the Peripatetic school. In 155 with two other philosophers Critolaus represented Athens on a political mission to Rome, where the trio's lectures inspired among intellectual patricians an abiding interest in philosophy, but led to Critolaus' dismissal from Rome by Cato the Elder.

(2) Greek politician: d. 146 B.C. As general of the Achaean League and demagogic enemy of the Roman protectorate over Greece, he incited the Achaeans into war with the Romans. In 146 B.C. the Romans routed the league's large army at Scarphaea in Locris—near which Critolaus soon afterward died—and within the year ended the political independence of Greece.

CRITTENDEN, George Bibb, American military officer: b. Russellville, Ky., March 20, 1812; d. Danville, Nov. 27, 1880. He graduated from the United States Military Academy in 1832, and he then served as an officer in the Mexican War, rising to the rank of lieutenant colonel. He joined the Confederacy at the out-

break of the Civil War, became a brigadier general and suffered defeat at Mill Springs, Ky., in 1862. He was kept under arrest in consequence and resigned his commission the following year. Later he served as a volunteer. From 1867-1871 he was state librarian of Kentucky.

CRITTENDEN, John Jordan, American legislator: b. Woodford County, Ky., Sept. 10, 1787; d. Frankfort, Ky., July 26, 1863. He was graduated at William and Mary College in 1807. In 1816 he became a member of the state legislature; in 1817 was elected to the United States Senate; and from 1827-1829 was United States district attorney. He was subsequently re-elected twice to the United States Senate. In 1848 he became governor of Kentucky. He was again attorney general under President Millard Fillmore and in 1855 was sent a fourth time to the Senate. In the Senate he urged unsuccessfully his famous compromise. After 1861 he served for one year in the House, and in that body also strove for the supremacy of the Constitution. Through his influence Kentucky remained loyal to the Union in the Civil War. See also **CRITTENDEN COMPROMISE**.

CRITTENDEN, Thomas Leonidas, American military officer: b. Russellville, Ky., May 15, 1819; d. Annandale, N. Y., Oct. 23, 1893. He was a son of John J. Crittenden (q.v.) and was educated for the law. In 1842 he became state attorney for Kentucky; served as an officer in the Mexican War and in 1849 was appointed consul at Liverpool. On the outbreak of the Civil War he became brigadier general of volunteers and in 1862 was promoted to major general. He distinguished himself at Shiloh, Stone River, and Chickamauga. He was retired in 1881.

CRITTENDEN COMPROMISE. A constitutional amendment proposed in 1860-1861 by John J. Crittenden (q.v.) of Kentucky, which represented the last desperate effort of the Southern Union Party to avoid secession and war. Under the terms of this amendment, the boundary between the free and slave states would have been set in line with the Missouri Compromise (q.v.), and the federal power committed to full and permanent support of slavery where it existed. Four resolutions were appended to the basic proposals, declaring the Fugitive Slave Act constitutional, urging repeal of the state personal liberty laws, promising suppression of two specially obnoxious features of the Fugitive Slave Law, and rigorous suppression of the outside slave trade. The legislatures of Virginia, Kentucky, Tennessee, and New Jersey instructed their delegates to the Peace Conference of 1861 to support the compromise. In Congress, Crittenden continued to press it during the session. It was lost in the House on Jan. 14, 1861, by 113 to 80; and in the Senate, on March 2, by 20 to 19. War became inevitable.

CRITTENTON, krīt'n-tūn, Charles Nelson, American philanthropist: b. Henderson, Jefferson County, N. Y., Feb. 20, 1833; d. San Francisco, Calif., Nov. 16, 1909. He engaged in the drug business in New York in 1861; but after 1882, when his four-year-old daughter Florence died, he devoted his time and wealth to the establishment of Florence Crittenton homes for homeless and unfortunate girls and their infant

children. In 1895 the National Florence Crittenton Mission was incorporated to carry on this work. Of these mission homes 75 were organized in Mr. Crittenton's lifetime in all the larger cities of the United States and in Marseille, France; Tokyo, Japan; Shanghai, China; Mexico City, Mexico.

CROATAN, krō-tān', a sound between the coast of Dare County, N. C., and Roanoke Island, in the channel joining Albemarle Sound with Pamlico Sound.

CROATIA, krō-ā'shī-ā (Slav. HRVATSKA), one of the six federal republics which constitute the Federal Peoples Republic of Yugoslavia. Its official name is Peoples Republic of Croatia. Covering an area of 21,701 square miles, the country occupies the northwestern and western sectors of Yugoslavia. It is U-shaped in form, the northern arm bordering Hungary and the southern stretching along the Adriatic Sea. Geographically it is delimited by 14° to 18°2' west longitude, and 42°6' to 46°30' north latitude.

Historically, Croatia is composed of three main parts: Croatia proper, Slavonia, and Dalmatia. According to the census of March 31, 1953, the population is 3,913,753, of whom 79 per cent are Croats, 14.5 per cent Serbs, and the remainder are national minorities—Hungarians, Italians, and others. The capital city is Zagreb (German Agram), with a population of 354,000. Other important cities are: Rijeka (Fiume), 75,000, a well-known harbor in the northern Adriatic; Split, 75,000, the capital of Dalmatia; Osijek, 55,000, the capital of Slavonia; Karlovac, 24,000, an important industrial center in upper Croatia; Pula (Pola), 28,000, a military port and arsenal in Istria; Varaždin, 18,000, a historical city in northern Croatia; and Dubrovnik (Ragusa), 17,000, world-famous tourist resort and historical town in southern Dalmatia.

Relief and Climate.—Croatia is predominantly highland, 70 per cent of the country being over 1,000 feet above sea level. While the north is characterized by the two rich agricultural valleys of the Sava and Drava rivers, the south is more mountainous and less fertile. The north and the mountain regions have a Continental climate, while the climate along the Adriatic coast is Mediterranean.

Social and Economic Conditions.—Socio-economically Croatia is predominantly an agrarian country, the peasantry constituting 75 per cent of the population. The agrarian reforms of 1919-1931, and of 1945, have distributed the land among the individual peasants, limiting the size of the individual holdings to 87 acres of arable land. Although since 1945 the formation of collective farms of the *kolkhoz* type and the socialization of agriculture have been promoted, individual peasant farms are nevertheless still largely prevailing. The social and economic conditions of the peasants in the north differ considerably from those in the south. In the north, the peasant farmers of Slavonia, generally speaking, are wealthy, while those of the heavily populated hilly areas, like Hrvatsko Zagorje, or those in Dalmatia in the south, hardly earn their living. Land utilization is distributed as follows: arable land 26.7 per cent; meadows and pastures 30.2 per cent; forests 33.5 per cent; vineyards and orchards 4 per cent; and unproductive land 4.3 per cent. The principal crops are corn, wheat,

oats, rye, and barley. Industrial plants, such as flax, hemp, sunflower, soya beans, sugar beet, and chicory, are grown mostly in Slavonia, while in Dalmatia oil and fig orchards are greatly cultivated. Animal husbandry has been developed in Slavonia with a special type of breed in the Sava Valley and the cattle ranches located in the Valley of Drava. Hog breeding, poultry farms, and apiculture are spread all over the country. In Dalmatia, mules and donkeys are used as draft animals instead of horses and oxen.

The infant period of Croatian industry dates back to the last decades of the 19th century but between World Wars I and II the industry expanded considerably. After World War II the industrialization of the country was fostered by the new regime which has given preference to heavy industry. Abundant forests favor timber production and there are sawmills scattered throughout the country. Agricultural industries comprise: sugar factories in Osijek and Zupanja; vegetable oil factories in Osijek and Zagreb; meat-packing plants in Petrinja, Zagreb, Križevci, and Bjelovar; breweries in Zagreb and Karlovac; dairy industries and alcohol distilleries located throughout northern Croatia and Slavonia; and fish canneries in Split, Komiza, and Zadar. The centers of the heavy industry—iron and steel works, machine and tool factories, and concrete factories—are Zagreb, Rijeka, Sisak, Karlovac, Split, Osijek, and Slavonski Brod (Brod), while the centers of the textile and leather industries are Varaždin, Duga Resa, Vukovar, and Zagreb.

The country has substantial stocks of lignite in Hrvatsko Zagorje, Raša (Istria), and northern Dalmatia, while bauxite is exploited in Dalmatia. The estimated production of lignite is approximately 1.2 million tons yearly. Limited quantities of iron ore are exploited in Petrova Gora, and although there are oilfields located in Slavonia and Medjumurje, the petroleum production is scant.

Hydroelectric plants have been constructed on the Kupa River near Karlovac, in Tribalj, and on the Krka and Cetina rivers in Dalmatia.

The first railroad was built in 1861, and since then the railroad system has expanded appreciably. The capital city is connected with all parts of the country, the main lines running east and west from Belgrade to Ljubljana, and north-south, between Vienna and Budapest to Rijeka and Split. The roads are mostly gravel although some hard-surfaced roads have been built. Coastal navigation is well organized, and is operated by state companies with shipyards in Rijeka, Kraljevica, and Split. The tourist traffic is increasing and, under normal conditions, can be of great economic importance to the country due to the extremely favorable geographical position of Dalmatia with its scenic beauty and attraction. The most important tourist centers are: Opatija (Abbazia) and Crikvenica in the Croatian littoral, and Rab, Hvar, Makarska, Korčula, and Dubrovnik in Dalmatia.

History and Government.—The Croats, a branch of the Slavic peoples, settled on their present territory in the 6th to 8th centuries. In the 9th century the first Croatian dukedom was established in Dalmatia, and in 852 its ruler Trpimir took the name of the duke of the Croats as marked in the first historical document bearing the Croatian name. In 910, Trpimir's successor, Tomislav, became the ruling prince, and in 925 he was crowned as the first Croatian king. The

kingdom founded by Tomislav embraced approximately the same territory as present Croatia, comprising the coastal provinces and the northern regions then called Pannonia. Tomislav was the founder of the Croatian national dynasty, and one of his successors, Petar Krešimir (1058–1074), succeeded in enlarging his kingdom, and proclaimed himself the king of Croatia and Dalmatia.

The era of the Croatian national dynasty is noted for continuous struggles of the two opposing groups: one advocating closer ties with and concessions to the pope and the Roman population of the littoral towns; the other, the nationalist group, defending zealously the old Croatian customs, rights, and privileges, especially those obtained in the Catholic Church, against Latin supremacy. King Dimitri Zvonimir (1076–1089), in the fight for the throne, accepted his royal insignia from Pope Gregory VII and thus became his vassal, but was killed soon after when attempting to lead the people into the war on foreign soil. Zvonimir was married to Lepa, sister of the Hungarian King Ladislas I, who after the death of his brother-in-law claimed the Croatian throne, and was supported in his endeavors by a part of Croatian nobility. The other group of Croatian nobles elected Petar Svačić, the last king of Croatian blood, who fell in the Battle of Petrova Gora in 1097 while defending his regime. In 1102, the representatives of the 12 Croatian tribes, and the Hungarian ruler Koloman (Kálmán) signed the *Pacta Conventa*, an interstate agreement, thus establishing the personal union between the two kingdoms, Croatia and Hungary.

As a consequence of this event, the center of the Croatian political and socio-cultural life began to shift from Dalmatia, the cradle of the Croatian state, to northern Croatia where, in 1094, a diocese had been established in the town of Zagreb which became in subsequent centuries the political and cultural center of the Croatian people. During the period from 1102 to 1527, Croatia was ruled by various dynasties: first by the Árpáds until 1301, then by the Angevins in the 14th century, and finally by the Polish dynasty of the Jagellos. At two different periods during this time—in the 14th and in the 15th century, under Stephen Tvrtko Kotromanić (r. 1353–1391) and Matthias Corvinus (r. 1458–1490)—Croatia was tied with neighboring Bosnia by strong constitutional links. When in the Battle of Mohács (1526), Louis II Jagello perished, the Croatian nobility elected Ferdinand of Habsburg as the king of Croatia, whose house ruled in Croatia until the end of World War I.

From the end of the 15th century until the beginning of the 18th century, the Croats were engaged in continuous battles against the invading Turks who, by the end of the 16th century, had conquered almost the whole of the country except for its northwestern part. At the same time the feudal burdens imposed by the Croatian landlords became unbearable for the peasants who repeatedly revolted demanding the reinstitution of the "Old Justice," that is, those liberties and freedoms which they had enjoyed in the pre-feudal era. The most famous of these revolts was that led by Matija Gubec, a peasant from Stubica in northern Croatia, in 1573.

The modern political history of Croatia started in the third decade of the 19th century, when the Croatian National Revival was generated by Ljudevit Gaj and his associates. In the revolu-

tionary year of 1848, the Croatian ban, Josip Jelačić, defended the Habsburg cause against the insurgent Magyars; but after the Hungarian resistance was crushed, instead of the promised freedom in Croatia as well as in Hungary, German absolutism was introduced. Defeated in 1866, Austria was compelled to compromise in 1867 with Hungary, who in turn made the compromise (*nagodba*) with Croatia in 1868. By this compromise, Croatia and Slavonia became an autonomous kingdom among the countries of St. Stephen's crown, with broad political, economic, and cultural rights. Dalmatia, which had been promised unification with Croatia and Slavonia, was forced to remain a separate province in the Austrian part of the dual monarchy.

The Compromise of 1868 became, in subsequent decades, the main object of dispute among Croatian political groups. While the Union Party defended the compromise, the National Party led by Bishop Joseph Georg Strossmayer, acknowledged it only in principle, but requested substantial changes in its provisions. The third party, the Croatian Party of the right, under the leadership of Ante Starčević, repudiated the compromise and demanded the establishment of a Croatian independent state. In 1904 a new party was born, the Croatian Peasant Party founded by the brothers Ante and Stefan Radić, whose aim was the organization of the peasantry, the struggle for social justice, and the realization of the political rights of the Croatian people. On Oct. 29, 1918, with the downfall of the Dual Monarchy, the Croatian Parliament in Zagreb proclaimed the independence of Croatia, and severed all the constitutional ties with Hungary and Austria. On Dec. 1, 1918, the union of Croatia with other southern Slav countries was proclaimed, and thus the Kingdom of the Serbs, Croats and Slovenes (since 1931 called Yugoslavia) was established.

Croatian history in the period between World Wars I and II is noted by the constant and persistent struggle against state centralism imposed by the Serbian ruling groups. By the Constitution of Vidovdan, of June 28, 1921, Croatia was first partitioned into six administrative departments (*oblasts*) which was later changed by King Alexander's Constitution of Sept. 3, 1931, into two provinces called *banovinas*—Savska and Primorska (Primorje). The main champion in this fight against Belgrade centralism was the Croatian Peasant Party which, after 1920, on all elections polled the overwhelming majority of Croatian votes. In 1932, under the influence of European totalitarianism, one group of Croatian Nationalists founded the Ustaši movement, demanding total separation of Croatia from the Yugoslav state. During this period the Communist Party was illegal and insignificant in its number of followers, but was nevertheless determined ideologically and well organized in the underground.

On Aug. 26, 1939, an agreement (*sporazum*) was reached between the Croatian Peasant Party, headed by Dr. Vladimir Maček, the Yugoslav regency, and several Serbian political groups; by this agreement Croatia and Dalmatia were united into one autonomous province called the Banovina of Croatia. Croatia's territory was increased by the addition of several districts of Bosnia and Hercegovina predominantly populated by a Croatian Catholic population. Although the agreement was under violent attack from both

Croatian Nationalists and dissatisfied Serbian groups, it nevertheless was accepted in principle, at home and abroad, by all moderate elements as a correct step toward the final settlement of the Serbo-Croatian dispute. With the German invasion of Yugoslavia on April 10, 1941, the "Independent State of Croatia" was proclaimed in Zagreb by the Ustaši leader, Ante Pavelić, who became the head of the new state. While Bosnia and Hercegovina were formally incorporated in Croatia, almost the whole of Dalmatia and the Croatian littoral had to be ceded to Italy by the Rome protocols of May 18, 1941. With the establishment of the Federal Peoples Republic of Yugoslavia in 1945, Istria, several islands in the Adriatic, and Baranja were included in the Republic of Croatia, while the Bosnian and Hercegovinian districts were detached.

Situated on a crossroad, and surrounded by powerful but seldom friendly neighbors, the history of the Croatian people has been a sequence of continuous struggles for survival and self-preservation; but in spite of all geopolitical odds and historical misfortunes, their continued presence is the proof of their perseverance and vitality.

Culture, Education, and Art.—Because of its situation on the crossway of various cultural trends, the Croatian culture is not uniform. While the north was largely influenced by German culture, in Dalmatia the Italian cultural trends were of preponderant significance. Finally, those Croats who live in Bosnia and Hercegovina came under the influence of the Byzantine and Moslem civilizations. Generally speaking, Western culture has left a strong imprint on Croatian cultural life as a whole which has been accentuated by the fact that the overwhelming majority of the Croats, almost 4 million, belong to the Roman Catholic Church.

Education is state controlled and is compulsory until the age of 14. In larger towns one or more high schools of European type offer higher training, while numerous special middle schools organized on the German or the Russian pattern provide technical preparation. The University of Zagreb was founded in 1619 as a college of philosophy, theology, and law by the Pauline Order in Lepoglava. In the 18th century it was transferred to Zagreb, and in 1874 was organized as a modern university having today seven departments and a great number of scientific institutes. The Adriatic Institute in Split leads the research pertinent to the phenomena of the Adriatic Sea.

The first Croatian book, a missal, was printed in 1483, while the Croatian classic literature began in Dalmatia, particularly in Dubrovnik and Split, in the first decades of the 16th century and flourished to the end of the 17th century. Marko Marulić (1450–1524), Petar Hektorović (1487–1527), Hanibal Lucić (1485–1553) and Ivan Gundulić (1589–1638) were the most prominent writers of this period.

The first literary works in northern Croatia were created in the 17th century, but the modern Croatian literature evolved *pari passu* with the national revival in the 19th century, romanticism and realism being equally represented. Ivan Mažuranić (1814–1890), Petar Preradović (1818–1872), and Silvije Strahimir Kranjčević (1865–1908) are the best known poets of this period, while August Šenoa (1838–1881), Eugen Kumičić (1850–1904), Antun Kovačić (1854–1889), Josip Kozarac (1858–1906), and August

Matoš (1873–1914), are the outstanding novelists.

Though a small nation, the Croats were in the past, and are today, very productive in the arts. The earliest Croatian monuments date from the period of the national dynasty, the oldest being the Church of the Cross in Nin (Dalmatia), dating from the last decades of the 8th century. The churches and the monasteries in Dalmatia, and the tombstones of Bosnia, evidence the creative spirit of the early Croatian artists.

In modern times the Croatian sculptor Ivan Meštrović (1883–) has achieved world renown, while other outstanding Croatian artists include: in sculpture, Antun Augustinčić (1900–), Robert Franges-Mihanović (1872–), and Voja Radauš (1895–); and in painting, Vlaho Bukovac (1855–1922), Celestin Medović (1859–1921), Ljubo Babić (1890–), and Joso Kljaković (1889–). Among the best known older composers in Croatia are: Vatroslav Lisinski (1819–1854), the composer of the first Croatian opera *Porin*, and Ivan Zajc (1831–1914), the composer of the popular opera *Nikola Šubić Zrinski*, while the more famous contemporary composers include, Krešimir Baranović (1894–), Jakov Gotovac (1895–), and Fran Lothka (1891–).

BRANKO M. PEŠELJ,
Associate, Mid-European Studies Center, New
York City.

CROCE, krô'châ, **Benedetto**, Italian philosopher: b. Pescasseroli, Aquila Province, Italy, Feb. 25, 1866; d. Naples, Nov. 20, 1952. He was sent at the age of nine to a Catholic boarding-school. During the course of his studies he lost his religious faith. Later, however, at Rome University, where he read moral philosophy, he found in the theory of the "ought to be" as opposed to the "is" the means of recovering his faith in life.

In 1886 he returned to Naples, where he lived until his death, and set himself to a study of political economy which resulted in a profound criticism of the Marxian doctrine. After a period of deep meditation, he started in 1902 his famous journal *La Critica* and published his *Aesthetic as the Science of Expression*, in which was formulated in embryo his philosophic system. His *Logic as the Science of Pure Concept*, *Philosophy of the Practical*, and *History, Its Theory and Practice* followed; and in these four volumes, which he united under the general title of *Philosophy of the Spirit*, Croce sets out his whole philosophy.

His system is based on an idealistic conception of reality, in which the real is seen as a dialectic of the spirit and nature is reduced to a mere aspect of this dialectic. Spirit, universal and eternal, which is brought into being through history, is conceived as a unity of four distinct and distinguishable, yet articulated, "grades," each linked to the other and conditioned by this contact in what Croce calls the "dialectic of distinction." These grades or stages of the spirit are further divided into two categories. On the one hand, there are the two grades which operate on the theoretical plane: art, visualized as pure intuition, the "dawn" form of knowledge, an a priori synthesis between content and form, in which one can recognize the qualities of lyricism and completeness; and philosophy, or logic conceived as the science of pure concept, the methodological stage in history, based on an a priori

synthesis between the universal and the individual "judgments." While on the other hand, there are the two grades which operate on the practical plane: economics, which expresses the stage of utility and forms the substance of politics; and ethics, which transmutes the stage of utility and elevates it to the realm of the universal. Through the interplay of the separate dialectics, therefore, theory and practice are integrated in the unity of the spirit. Nevertheless, each individual grade of the spirit draws life from its own internal dialectic which is, in the Hegelian sense, a "dialectic of opposition" and which resolves itself in an a priori synthesis. Thus, the a priori synthesis of the Kantian philosophy remains the basis for this grandiose and complex idealism.

In his *History, Its Theory and Practice*, Croce further enlarges the analysis of the grade of philosophy. Here, he considers the a priori synthesis of logic as a manifestation of the historical judgment and so identifies philosophy with history. History is, thus, the concrete expression of the individual judgment as it at once penetrates and forms reality.

Other important works are his *Saggio sullo Hegel*, *Saggio sul G. Vico*, *Nuovi Saggi di Estetica*, *Estetica e Politica*, *La Storia come Pensiero e come Azione*, *Il Carattere della Filosofia moderna*. As a result of a deep study of the validity of his theory, he produced a vast series of critical essays on the history and literature of many countries.

He also wrote histories of Italy and of Europe, both of which appeared during fascism. Because of his worldwide reputation, however, that government did not dare to ban either of these works, despite their liberalism.

A great philosopher and critic, an indefatigable worker and a forceful personality, Croce has left teachings of the greatest importance to the moral and social knowledge of man.

PIERO FOSSI,
Doctor of Philosophy, Florence, Italy.

CROCIDOLITE, krô-sid'ô-lit, a mineral of the amphibole group composed of long, delicate fibers and also occurring massive and earthy, and then called abriachanite. It has the formula $\text{NaFe}(\text{SiO}_3)_2\text{FeSiO}_3$, part of the iron being frequently replaced by magnesium and calcium and part of the sodium by hydrogen. The mineral has a hardness of 4 and a specific gravity of about 3.25. The fibrous varieties have a silky luster and vary from blue to green. One of the chief sources of crocidolite is in Griqualand, South Africa. See also ASBESTOS.

CROCKER, Charles, American capitalist: b. Troy, N. Y., Sept. 16, 1822; d. Monterey, Calif., Aug. 14, 1888. He received a common school education and went to California in 1850, where he opened a store. In 1860 he was elected to the state legislature. With Leland Stanford, Mark Hopkins, and Collis P. Huntington, he projected and completed the Central Pacific Railroad.

CROCKETT, krök'ët, David, American pioneer: b. near Limestone, Washington County, Tenn., Aug. 17, 1786; d. the Alamo, Texas, March 6, 1836. He had little formal schooling, and adapted himself early to the life of a farmer and hunter. A pioneer in the development of western Tennessee, he served as a scout for Gen. Andrew Jackson in the Creek War (1813–

1814) and later was made a colonel in the Tennessee militia. In 1821 and again in 1823 he was elected to the Tennessee legislature, and in 1826 was persuaded to run for Congress as the representative from what is now Gibson County, serving for two terms (1827-1831). His opposition to President Jackson's Indian removal bill lost him the 1830 election, but he was returned to Washington for the 23d Congress (1833-1835). A natural shrewdness and a ready wit gained him a wide following, but his divergence from the Democratic Party line cost him his seat in the following election. In February 1836 he joined the Texans in their war against Mexico, and was one of the 187 defenders of the Alamo slain by the forces of the Mexican general, Antonio López de Santa Anna, on March 6, 1836.

The most authentic of the writings attributed to him are *A Narrative of the Life of David Crockett* (1834) and *An Account of Colonel Crockett's Tour to the North and Down East* (1834), both of which were probably dictated.

Consult Seitz, Don C., "David Crockett—who died for Texas" *Uncommon Americans* (Indianapolis 1925); Crockett, David, *The Adventures of Davy Crockett Told Mostly by Himself* (New York 1934); Rourke, Constance, *Davy Crockett* (New York 1934).

CROCKETT, Samuel Rutherford, Scottish novelist: b. Little Duchrae, New Galloway, Scotland, Sept. 24, 1860; d. Avignon, France, April 21, 1914. Educated at Edinburgh University, he entered the Free Church of Scotland ministry in 1886, and became pastor at Penicuik, Midlothian. The success of his first literary effort, *Dulce Cor: the Poems of Ford Bereton* in 1886 and of *The Stickit Minister* (1893), a series of essays, encouraged him to resign from the ministry in 1895 and to devote himself to a career in writing. He subsequently produced almost 50 novels, using as his locale his native Galloway in the tradition of the "Kailyard School" of which he was one of the foremost exponents together with Ian Maclaren and James M. Barrie. Other of his works are *The Raiders* (1894), *The Lilac Sunbonnet* (1894), *The Standard Bearer* (1898), *The Dark o' the Moon* (1902), *Maid Margaret* (1905), *The White Plumes of Navarre* (1909), and *Sandy's Love Affair* (1913).

CROCKETT, city, Texas, and Houston County seat. Located in east central Texas between the Trinity and Neches rivers. Named for Davy Crockett of Alamo fame, it was incorporated in 1837, and is the fifth-oldest town in Texas. It is 120 miles north of Houston and is served by the Missouri Pacific Railroad besides being crossed by seven major highways. The mean annual temperature is 69 degrees, the average rainfall, 45.39 inches, and the altitude, 350 feet. It is governed by a city council, and is a trade center for lumber and cotton, with cottonseed oil and lumber mills, woodworking plants, and cotton gins. There is also diversified farming. It is the seat of Mary Allen College, and is notable for the presence of a replica of the first Spanish mission in East Texas (1690). Pop. (1950) 5,932.

CROCODYLE, any one of fourteen members of the genera *Crocodylus* or *Osteolaemus* of the order Crocodylia (q.v.). Crocodiles, together with the Asiatic garials, are readily distinguished from their allies, the caimans (South

and Central America) and alligators (southeastern North America and China), by the enlarged fourth lower tooth fitting into an emargination of the upper jaw instead of into a cavity as with the alligators, so that it shows conspicuously when the mouth is closed. Though the narrow snout of the American crocodile distinguishes it from the very broad-snouted American alligator, the character is not of universal application, for several crocodile species have broad snouts. In true crocodiles (*Crocodylus*), as distinct from the African *Osteolaemus* and the alligators, but not the caimans, the nasal opening in the skull is not divided by a forward prolongation of the nasal bones. While the valvular nostrils are situated on the extremity of the snout to facilitate breathing when the rest of the reptile is submerged, the internal nasal opening of recent crocodiles is set far back on the palate where it connects with the windpipe. This arrangement enables a crocodile to breathe when its jaws are open underwater to hold its prey. The ear openings also can be closed.

Crocodiles swim by means of the webbed feet and lateral movements of the powerful compressed tail, on whose upper surface is a double series of horny lobes that converge to form a single keel on the distal half. The tail serves

Crocodile (*Crocodylus americanus*).

also as a weapon, being employed to strike the legs from under any unsuspecting creature that approaches too near the water's edge—the victim is then quickly seized, dragged in, and held under until drowned. If too bulky for immediate dismemberment, the corpse is stowed among roots or beneath a river bank until sufficiently decomposed to be torn apart and swallowed. The teeth of a crocodile being ill-adapted for mastication, the food is ground by the mass of pebbles usually carried in the stomach for the purpose.

Most crocodiles excavate a hole on land in which to deposit their numerous hard-shelled eggs, each about the size of a duck's. A few species like the Estuarine Crocodile (*C. porosus*) raise dome-shaped nests of vegetable debris whose fermentation assists incubation. This ocean-going reptile ranges from India to the Fiji Islands and is a notorious man-killer. Many people also fall victim to the African Crocodile (*C. niloticus*), abundant in most of the larger lakes and rivers of that continent. In the Ganges the Mugger or Marsh Crocodile (*C. palustris*) plays a useful role as a scavenger of the corpses consigned to that sacred river. *C. americanus* is now rare in southern Florida though still common farther south.

CROCODYLIA, krök-ô-dīl'î-â, an order of the Reptilia (q.v.) consisting of the alligators, caimans, crocodiles, garials, and many fossil forms. Of the five suborders only one (Eusuchia) has any living representatives. Of amphibious habits, members of the order are characterized by their massive, lizard-like build,

having forelimbs somewhat shorter than the hind ones, and a long tail. However, the cloacal opening is longitudinal and the male copulatory organ single and anterior. Recent crocodilians, at least, are encased in a protective armor of horny shields overlying bony plates. Largest of all living reptiles, crocodilians are unique in possessing a practically four-chambered heart, the ventricle being almost completely divided; venous blood is supplied to the viscera while arterial blood nourishes the body walls, limbs, and head. The snout is more or less elongate, the usually sculptured skull tending to be broad and flattened posteriorly, with large, fixed quadrate and strong quadratojugal arch. The numerous teeth, designed for holding, are typically thecodont, the forward ones conical and pointed, the rear ones sometimes blunter. The presacral vertebrae are procoelus in advanced forms; abdominal ribs are compound; and both pubic bones are simple and connected by cartilage with the relatively short and broad ischium.

Though living crocodilians are confined to tropical or subtropical regions, in bygone eras their distribution was probably world-wide, numerous fossil forms having been found in northern Europe and as far north as Canada in the Americas.

The earliest known crocodilians (*Protosuchia*) occur in the Triassic, so the group is a very ancient one. Though they resemble the *Thecodontia* in many ways, these ancestral forms agree with more recent types in such diagnostic characters as structure of the otic region, type of coracoid, elongate carpals, partial elimination of the pubis from the acetabulum, and the like. Crocodilians essentially similar to modern types (*Mesosuchia*) first appeared in the early Jurassic and abounded during the Cretaceous. While their pterygoids fail to participate in the formation of a secondary palate, these reptiles agree with their successors in having the pubis completely excluded from the acetabulum. With the later Mesozoic arose the modern crocodilians (*Eusuchia*) whose principal characteristic is the entrance of the pterygoids into the formation of the secondary palate. They flourished during the Tertiary, and the 25 surviving species are but a remnant of the once numerous order. Of the two other suborders distinguished, the *Sebosuchia*, known from the Cretaceous, Eocene, and Miocene of South America, consists of a few species with crested skulls that are much higher and narrower than in other groups. The *Thalattosuchia*, occurring chiefly in the Jurassic, though a few are known from the Cretaceous, are marine forms with short pectoral paddles in place of forelimbs, and tails not unlike those of the ichthyosaurs.

For further details consult A. S. Romer, *The Osteology of Reptiles* (Chicago 1954).

CROCOITE, krō'kō-it, lead chromate (PbCrO_4), is a mineral crystallizing in the monoclinic system. It is found as slender prisms, in vertically striated columnar aggregates, and in granular form. Bright hyacinth red in color with orange-yellow streaks and of adamantine to vitreous luster, it has a hardness of 2.5 to 3 on the Mohs' scale and a specific gravity of 6.0. Its chemical composition is PbO (lead oxide) 89.9 per cent and CrO_3 (chromic oxide) 31.1 per cent. A rare mineral, not abundant enough to be of commercial value except as a pigment of

chrome yellow, it is historically interesting because in it Louis Nicolas Vauquelin (q.v.) first discovered the element chromium in 1797. The best specimens, prisms about 3 or 4 inches long and of brilliant color and luster, are found in Tasmania. Crocoite also occurs in Rumania, Siberia, the Ural Mountains, and in the vulture district of Arizona.

CROCUS, krō'kūs, in Greek mythology, a youth who was enamored of the nymph Smilax. He was changed by the gods into the flower which was named after him. According to another tradition, he was metamorphosed by his friend, the Olympic god Hermes, who had killed him by accident while playing a game of discus.

CROCUS, a genus of about 80 species of hardy bulbous plants belonging to the iris family (Iridaceae), with fleshy corms and basal, grass-like dark green leaves. Lacking a true stem, the goblet-shaped white, yellow, or lilac flowers, 3 to 5 inches long, appear either in spring or autumn and raise their expanded segments above ground by a long, slender perianth-tube. Native to Europe and southwestern Asia, they have been cultivated since antiquity. A number of species are grown today in the United States as garden flowers; the numerous horticultural forms of Dutch crocuses derived mostly from *C. aureus* and *C. vernus* are particularly famous. Corms of known species and forms should be planted several inches deep in good and well-drained soil, as new corms are formed on top of the old. Seeds are used when new varieties are desired.

Saffron, Spanish Saffron, True Saffron, etc. (*C. sativus*), an autumn-blooming species, contains a coloring agent (saffron) composed of picrocrocin (a bitter glucoside), crocin (a yellow powder), 1 per cent volatile oil, fixed oil, and wax, found chiefly in the three long, orange-colored, convoluted, and fragrant stigmas. Ancient and medieval physicians used saffron as a nerve sedative. Today it is used for coloring and flavoring.

CROES, John James Robertson, American civil engineer: b. Richmond, Va., Nov. 25, 1834; d. 1906. Graduated from the College of St. James, Maryland, in 1853, he began practice as a civil engineer three years later. From 1865 to 1870 he was resident engineer of the first high masonry dam in the United States at Boyd's Corners, New York. Later he became topographical engineer for the New York City Park Department (1872-1878) and chief engineer of the Suburban Rapid Transit Railroad in New York City (1885-1891). His expert reports on the problems of reservoirs, dams, sewerage, waterworks, and like matters, were sought by various cities. He was a contributor to numerous engineering journals, principally the *Sanitary Engineer*, from 1880 to 1890, and president of the American Society of Civil Engineers (1901).

CROESUS, krē'sūs, king of Lydia, last of the Mermnadæ line. He succeeded his father, Alyattes, in 560 B.C., extending his territory by conquest to include the region from the north and west coasts of Asia Minor to the Halys (Kizil Irmak) River. The vast wealth which he amassed from the mines of his dominion and in trade with his neighbors has become proverbial.

Sardis, his capital city, was a center of arts and letters. He contributed generously to the rebuilding of the Artemesium at Ephesus and made offerings to many Greek oracular shrines, especially that at Delphi.

His interpretation of the Delphic oracle's saying encouraged him to war with Cyrus, king of Persia. He was defeated and taken prisoner by the latter at Sardis in 546 B.C. Herodotus relates that Croesus, condemned to the funeral pyre by Cyrus, repeated the name of Solon three times. On being asked by Cyrus for an explanation, Croesus told how, at the height of his success and wealth, he had asked Solon, "Am I not the happiest of men?" and the philosopher had replied, "I pronounce no man fortunate until his death." Impressed by the story, Cyrus spared Croesus' life and later made him a trusted friend, and a power in his court, recommending him to the favor of his son Cambyses after his own death. Herodotus relates further that when Cambyses went mad, he ordered Croesus killed, but Croesus' life was saved by the king's servants.

Consult How, W. W. and Wells, Joseph, *A Commentary on Herodotus* (Oxford 1912); Jebb, Richard C., *Bacchylides* (London 1905).

CROFFUT, William Augustus, American author: b. Redding, Conn., Jan. 29, 1835; d. Washington, D.C., Aug. 31, 1915. He was educated in the public schools and received a Ph.D. from Union College. He entered the field of journalism in 1852, became a private in the U.S. Army during the Civil War, and, on his release, returned to journalism, working, at various times, as editor of the *Minneapolis Tribune*, the *New York American*, the *Rochester (N.Y.) Democrat*, the *American Architect*, and *Heath and Home*, among others. From 1888 to 1894 he was executive officer of the U.S. Geological Survey, and in 1899 he organized and became secretary of the Anti-Imperialist League as well as president of the Liberty League. He is the author of *A War History of Connecticut* (1867), *A Helping Hand for American Homes* (1868), *A Midsummer Lark* (1882), *Fifty Years in Camp and Field* (1909); several volumes of verse, including the opening ode for the Chicago Exposition of 1893; many pamphlets; and *Deseret*, an opera with music by Dudley Buck (1882).

CROFT, krôft, or CROFTS, William, English composer and organist: b. Nether-Ettington, Warwickshire, England, Dec. 30, 1678; d. Bath, Aug. 14, 1727. A student of Dr. John Blow at the Chapel Royal, he had, by 1700, collaborated in the publication of a collection of *Ayres for the Harpsichord or Spinnet* and had been appointed organist of St. Anne's Church in Soho. In 1707 he became organist of the Chapel Royal, and a year later succeeded his teacher, Dr. Blow, as official organist of Westminster Abbey. With this position he also assumed the duties of master of the children and composer to the Chapel Royal. He composed numerous odes, anthems, songs, and sonatas for flutes and violins; his most outstanding work, however, was the *Musica Sacra*, which was published in two volumes in 1724. Included in this choral group was the burial service, which still forms the classic setting of the Anglican Church ritual, sections of it being played on almost every ceremonial occasion. He was an original member of the Academy of Vocal Musicians at its founding in 1725.

CROFTER, krôft'er, a term applied throughout the highlands of Scotland to a type of small farmer who rents or cultivates a limited holding of land. The crofters, or cotters, are for the most part descendants of clan members who paid rent in lieu of personal services. They live chiefly in crofting townships or parishes and enjoy grazing and peat-cutting rights in joint tenancy with their neighbors.

Many crofters were displaced in the 19th century to make way for deer forests and sheep farms. Some emigrated to other countries while others resettled near the seashore where they could add to their meager income by fishing. Their grievances were investigated by a parliamentary commission in 1883 which secured the passage of the Crofters' Holding Act of 1886. Under this act their holdings were defined as from 3 to 10 acres of arable land and their rent was not to exceed £30 a year. In Argyle, Sutherland, Inverness, Caithness, Ross and Cromarty, Orkney, and Shetland counties, to which this legislation was limited, there were estimated to be 40,000 crofting families, and crofters are also found in other counties. See also SCOTLAND.

CROGHAN, krô'gân, George, American military officer: b. near Louisville, Ky., Nov. 15, 1791; d. New Orleans, La., Jan. 8, 1849. Entering military life after his graduation from William and Mary College in 1810, he distinguished himself at Fort Meigs and Fort Stephenson in 1813, winning the rank of lieutenant-colonel and a congressional medal for bravery. He resigned from the army in 1817 and served briefly as postmaster at New Orleans in 1824, but re-enlisted in the regular army a year later as an inspector-general. In 1846 he was a colonel with Gen. Zachary Taylor's forces in Mexico and took part in the Battle of Monterrey.

CROKER, krô'kër, John Wilson, British statesman and writer: b. Galway, Ireland, Dec. 20, 1780; d. Hampton, England, Aug. 10, 1857. After obtaining his B.A. degree from Trinity College, Dublin, he studied at Lincoln's Inn for two years and was admitted to the Irish bar in 1802. He entered Parliament in 1807 from Downpatrick, serving continuously until his resignation in protest against the Reform Bill of 1832. In 1807, also, he was appointed deputy chief secretary for Ireland, and three years later became secretary of the Admiralty, a post he held for 20 years under various governments.

His literary career began in 1804 with *Familiar Epistles on the Irish Stage*, a clever satire. In the same year, *Songs of Trafalgar* established him as a poet, while *A Sketch of the State of Ireland, Past and Present* (1808) proved him an able political pamphleteer. Much of his critical output found an outlet in the *Quarterly Review* with which he became associated at its inception in 1809. Here he published biting criticisms of Keats' *Endymion* (1818) and of Macaulay's *History of England*, the latter in retaliation for Macaulay's attack on his own best work, an edition of Boswell's *Life of Johnson* (1831). Disraeli satirized him as Rigby in *Coningsby*, but despite all criticism he continued his essays in the *Quarterly Review* until 1854 and was at work on an annotated edition of Pope at the time of his death. Other of his works are *The Battles of Talavera*, a poem (1809), *Stories for Children from the History of England*

(1817), and *Military Events of the French Revolution of 1830* (1831).

Consult the *Crocker Papers*, 3 vols., ed. by Louis L. Jennings (London 1884), and Brightfield, M. F., *John Wilson Crocker* (Los Angeles 1940).

CROKER, Richard, American politician: b. Clonakilty, Ireland, Nov. 23, 1841; d. Glencairn, April 29, 1922. His parents emigrated to the United States when he was a child and he was educated in the public schools of New York City. He joined Tammany Hall in 1865, becoming a member of the faction opposing "Boss" Tweed. In 1868, 1870, and 1883 he was elected an alderman of New York City, and held, in addition, the offices of coroner (1873-1879), fire commissioner (1883), and city chamberlain (1889-1890). Meanwhile he rose as a power in Tammany Hall until he became its acknowledged leader in 1886. His leadership was discredited in 1894, however, and he went to England, but returned in 1897 to elect Robert C. Van Wyck as first mayor of greater New York. With the election of a fusion candidate four years later, Crocker's power again waned and he retired to England and later, Ireland. He maintained racing stables at Glencairn, winning the Derby in 1907.

CROKER, Thomas Crofton, Irish antiquary: b. Cork, Ireland, Jan. 15, 1798; d. London, England, Aug. 8, 1854. While apprenticed as a youth to a Cork merchant, he found time to travel about southern Ireland, recording its songs and legends, some of which were favorably received by Thomas Moore and included in his *Irish Melodies* (1818). Crocker obtained a clerkship at the Admiralty in London in 1819, and held it until 1850, meanwhile continuing his literary activities. His first major work, *The Fairy Legends and Traditions of the South of Ireland* (1825), was well received as were his *Legends of the Lakes* (1829) and *Popular Songs of Ireland* (1839), all of which evidenced careful scholarship combined with a pleasing facility of expression.

Crocker was also active in the Society of Antiquaries and helped to found the Camden Society in 1839 for which he wrote *Narratives Illustrative of the Contests in Ireland in 1641 and 1690* (1841). In addition he was a founder of the Percy Society (1840), to which he dedicated *Historical Songs of Ireland* (1841), and of the British Archaeological Association (1843), and registrar of the Royal Literary Fund (1837-1854).

CROLL, kröl, James, Scottish geologist: b. near Coupar-Angus, Perthshire, Scotland, Jan. 2, 1821; d. Perth, Dec. 15, 1890. Despite a limited elementary school education, he advanced himself to a position of scientific prominence through independent study. In 1859 he was appointed keeper of the Anderson College museum in Glasgow, and from 1867 to 1881 was keeper of maps and correspondence for the Geological Survey of Scotland at Edinburgh. His most important contribution to geological climatology was *Climate and Time* (1875) for which he was elected to the Royal Society in 1876. He also produced such other works of scholarship as *The Philosophy of Theism* (1857), *Discussions on Climate and Cosmology* (1886), *Stellar Evolution* (1889), and *The Philosophic Basis of Evolution* (1890).

CROLY, krölī, David Goodman, American journalist: b. Clonakilty, County Cork, Ireland, Nov. 3, 1829; d. New York, N. Y., April 29, 1889. Taken to the United States as a child, he attended New York City schools and New York University (1854). He joined the staff of the *New York Evening Post* in 1855, but left it in 1857 to found the Rockford, Ill., *Daily News* with his wife, Jane Cunningham Croly (q.v.). With the failure of the *News* he returned to New York City, to become managing editor of the *World* (1862-1872) and founder and editor of the *Real Estate Record and Builders' Guide* (1868-1873) and the *Modern Thinker* (1873). In 1873 also he transferred to the *Daily Graphic*, where he remained until 1878.

Croly's *A Primer of Positivism* (1871) sought to popularize that philosophy in the United States. In other works, *Miscegenation* (1864), a collaboration; *Truth* (1872); and *Glimpses of the Future* (1888), he evinced an independent, iconoclastic spirit.

CROLY, George, Irish author and cleric: b. Dublin, Ireland, Aug. 17, 1780; d. London, England, Nov. 24, 1860. He was ordained in the Anglican Church ministry in 1804 after studying at Trinity College, Dublin. Dissatisfied with his curacy, he went to London in 1810 where he wrote for various journals and, in 1817, published his first book of poetry, *Paris in 1815*, in imitation of Byron's *Childe Harold*. Other poetic works were *The Angel of the World* (1820) and the tragedy *Catilina* (1822).

Croly was more successful with his historical novels, *Salathiel* (1829) and *Marston* (1846), which were sensational in style and imitative of de Quincey and Moore. He eventually obtained a pastorate at St. Stephen's, Walbrook, London, in 1835 and held briefly the chaplaincy of the Foundling Hospital in 1847.

CROLY, Jane (nee CUNNINGHAM; pseudonym JENNIE JUNE), American journalist: b. Market Harborough, Leicestershire, England, Dec. 19, 1829; d. New York, N. Y., Dec. 23, 1901. She arrived in the United States in 1841, and lived in Poughkeepsie, N. Y., where she was privately educated. She began her writing career with syndicated fashion articles and, following her marriage to David G. Croly (q.v.) in 1857, continued to pioneer as a woman journalist. From 1860 to 1887 she edited *Demorest's Illustrated Monthly* and at various times was associated with the *Home-Maker* and *Godrey's Lady's Book*. She was a New York correspondent for such newspapers as the *New Orleans Picayune* and the *Baltimore American*, and was also on the staff of the *New York World*, *Times*, and *Graphic Daily Times*.

Equally active as an organizer, she called the first woman's congress in 1856; founded Sorosis, the first important woman's club (1868); and organized the Women's Press Club (1889). She was the author of *The History of the Woman's Club Movement in America* (1898). Other, less notable works were *Jennie June's Cookery Book* (1866) and *For Better or Worse* (1875).

CRO-MAGNON MAN, krō-mā-nyôn', the name given to the portions of four prehistoric skeletons found in the Cro-magnon cave near Les Eyzies, Dordogne, France, in 1886. These skeletons are considered to be those of a type

of man who inhabited southwestern Europe in the late Paleolithic period. Considered the closest prototype of modern man, they appeared to be about six feet tall, with a capacious cranium, high forehead, narrow nose, and prominent chin. The remains of weapons, ornaments, and polychrome art found with them denote an advanced stage of culture. See also MAN, PREHISTORIC RACES OF.

CROMARTY. See ROSS AND CROMARTY.

CROMARTY FIRTH, an inlet of the sea on the east coast of Scotland, extending 18 miles inland from the Moray Firth in a southwesterly direction through the county of Ross and Cromarty. Protected at its entrance by the Sutors of Cromarty, two headlands over 400 feet high, it has a width of from 3 to 5 miles and a depth ranging from 5 to 40 fathoms. Because it is completely landlocked, it serves as an excellent shelter for shipping and was used as a base by the Royal Navy during World War I.

CROME, krôm, John, English landscape painter: b. Norwich, England, Dec. 22, 1768; d. there, April 22, 1821. The founder and chief painter of the Norwich school of painting in Britain, he served an apprenticeship of seven years with a coach, house, and sign painter, but, except for what he learned in this trade, was largely self-taught. A Norwich collector of paintings allowed Crome to study the Gainsboroughs in his gallery, and the young painter was also strongly influenced by the works of Richard Wilson. In 1803 he helped to found the Norwich Society of Artists, and sent landscapes to the first exhibition of the society in 1805. The following year he also contributed to the Royal Academy Exhibition in London.

In 1814 Crome visited Paris for the first time and on his way back to England, traveled through Belgium. Two pictures, the *Boulevard des Italiens* and the *Fishmarket at Boulogne*, which are in the gallery at Norwich, directly reflect this voyage. Of about this same time are his two best-known works, *Mousehold Heath* and *Porringland Oak*, both of which are now in the National Gallery in London.

Crome had a great admiration for Joseph Mallord William Turner, who seems in return to have borrowed, in at least one picture, from Crome. As a mature artist, Crome also studied with the greatest respect the paintings of the 17th century Dutch landscapist Meindert Hobbema, and, though he seems to have imitated the latter in choosing motives, he always kept his personal naturalistic approach. He was also a pioneer in the field of engraving. Many paintings are wrongly ascribed to Crome because he had a great number of pupils, close followers, and imitators. To distinguish him from his son, John Berney Crome (1794-1842), who was also a painter, the elder Crome is called "Old Crome."

Bibliography.—Dickes, William F., "John Crome," *The Norwich School of Painting*, chaps. 1-3 (London 1905); Holme, Geoffrey, ed., "John Crome," *The Norwich School*, pp. 8-16 (London 1920); Baker, Charles H. C., *Crome* (London 1921); Smith, Solomon C. K., *Crome, with a Note on the Norwich School* (London 1923); Nottram, Ralph H., *John Crome of Norwich* (London 1931); Redgrave, Richard, and Redgrave, Samuel, "John Crome," *Century of British Painters*, pp. 347-357 (Oxford 1947).

CROMER, Evelyn Baring. See BARING, EVELYN.

CROMLECH, krôm'lêk, the name given to a kind of megalithic sepulchral monument of prehistoric times. Consisting of three or more columns of unhewn stone supporting a large tabular block which form a rectangular chamber, it usually contains a chamber or cist beneath its floor enclosing a skeleton with arms, stone implements, or other relics. Sometimes the cromlech was encircled by a ring of standing stones, and sometimes it was itself buried beneath a large mound of earth.

Cromlechs are found throughout Great Britain and in Europe, Asia, and America. Among the most remarkable cromlechs in England are Kit's Coty House, near Aylesford, Kent; Chun Quoit, Cornwall; and Plas Newydd, Anglesey. Those in Scotland include the Auld Wives' Lifts, near Craigmaddie House, Stirlingshire, and the Witch's Stone at Bonnington Mains, near Edinburgh. See also DOLMEN.

CROMMELIN, krôm-mê-lân', Andrew Claude de la Cerois, shâ-rwâ', English astronomer: b. Cusshendun, County Antrim, Ireland, Feb. 6, 1865; d. London, England, Sept. 20, 1939. Educated at Trinity College, Cambridge (1886), he became assistant master at Lancing College in 1889 and later joined the Royal Observatory at Greenwich (1891-1927), where he specialized in the study of the orbits of comets and minor planets. A council member, and later president (1904-1906), of the British Astronomical Association, he took part in its eclipse expeditions in 1896, 1900, and 1905, and participated in the solar expedition to Brazil in 1919. With P. H. Cowell, he published a study of the motion of Halley's comet from 240 B.C. to 1910 A.D. He wrote numerous scientific articles and was co-author, with Mary Proctor, of *Comets* (1937). He was president of the Royal Astronomical Society, 1929-1930.

CROMMELYNCK, krôm-û-lêk', Fernand, Belgian dramatist: b. Brussels, Belgium, 1888. A member of a family closely connected with the theater, he gained an early and complete theatrical training and began both to act and to write for the stage. From the beginning he showed unusual skill in creating morbid atmospheres. *Nous n'irons plus au bois* (1906), the first play of this early period, met with little critical acclaim, and its successors, *Le Sculpteur de masques* (1908) and *Le Marchand de regrets* (1913), were also coolly received. It was not until *Le Cocu magnifique*, a lyrical farce, was produced in Paris at Lugné-Poë's Théâtre l'Oeuvre in 1920, that he gained international fame.

Moving to Saint-Cloud, near Paris, he devoted his time entirely to writing. His next play, *Les Amants puerils* (1923), was less successful, but *Tripes d'or* (1930) renewed his prestige and was produced in Russia by Vsevolod Meyerhold. *Carine, ou la Jeune Fille folle de son âme* (1934) again showed him to be an expert dramatist of strong lyric power; *Une Femme qui a le coeur trop petit* (1934) had even wider appeal. But his increasing concentration on dramatic technique lessened the force of his writing, and *Chaud et froid* (1936) fell below his earlier achievements.

CROMPTON, krûmp'tûn, Henry, English philosopher: b. Liverpool, England, Aug. 27,

1836; d. Surrey, March 15, 1904. After graduating from Trinity College, Cambridge, in 1858, he became a clerk of the court of assize on the Chester and North Wales circuit, and held this post for 43 years. His interest was aroused in the positivist philosophy of August Comte and he began to take an active part in the positivist movement in England. In addition he absorbed himself in social questions of the day, notably the trade-union movement. From these interests came his best-known works, *Letters on Social and Political Subjects* (1870), *Industrial Conciliation* (1876), and *Our Criminal Justice* (1905).

CROMPTON, Samuel, English inventor: b. Firwood, near Bolton, England, Dec. 3, 1753; b. Bolton, June 26, 1827. Forced to work at home as a child on the crude spinning jenny of the time, he resolved to improve the machine, and in 1779 perfected the much-improved spinning mule. It combined the best features of Hargreave's spinning jenny and Arkwright's roller-frame with a spindle carriage which made possible the production of a very fine yarn. Although his machine laid the basis for muslin manufacture in Britain, he was financially unable to patent it, and was forced to release it to the public on the promise of a subscription from its users. The promise barely materialized and, disheartened, Crompton resumed spinning on his own machine. Private subscription later brought him a limited sum, and the House of Commons granted him £5,000 in 1812 which he invested in private enterprise, first as a bleacher and later as a cotton merchant.

CROMWELL, kröm'wēl, Bartlett Jefferson, American naval officer: b. near Springplace, Ga., Feb. 9, 1840; d. June 24, 1917. Graduated from the U.S. Naval Academy in 1861, when the Civil War was already in progress, he was first assigned to the *Iroquois*, and then joined the South Atlantic Blockading Squadron in 1862. He participated in naval attacks on Morris Island, off Charleston, S. C., commanded the captured Confederate ram, *Atlanta*, on its journey to Philadelphia in 1863, and was transferred to the East Gulf Squadron the same year. He was commissioned a commander in 1874, and served as inspector of ordnance at navy yards in Philadelphia (1874-1878), Portsmouth (1882-1884), and League Island (1886-1889). Following his promotion to commodore in 1898, he was sent to Havana, Cuba, to receive the surrender of its naval station at the conclusion of the Spanish-American War, and remained as its commander. In 1901, with the rank of rear admiral, he commanded in South American and European waters.

CROMWELL, Henry, English administrator: b. Huntingdon, England, Jan. 20, 1628; d. Soham, Cambridgeshire, March 23, 1674. The fourth son of Oliver Cromwell, he served as a colonel under his father in Ireland in 1650, was nominated to Parliament from Ireland in 1653, and returned there in 1654 as commander of the Irish Army with the rank of major-general and member of the ruling council. In 1657 he became lord deputy and, a year later, lord lieutenant and governor general. Although he was popular with the people because of his consideration and justice, he was recalled by Parliament in 1659, and he subsequently retired to Spinney Abbey in Cambridgeshire.

CROMWELL, Oliver, lord protector of England: b. Huntingdon, England, April 25, 1599; d. London, England, Sept. 3, 1658. He was the second son of Robert Cromwell and Elizabeth Steward. His father was the second son of Sir Henry Cromwell and grandson of Sir Richard Williams who had taken the surname of Thomas Cromwell, his uncle and patron.

Oliver was educated at a free school in Huntingdon. In 1616 he entered Sidney Sussex College, Cambridge, described by Bishop Laud as a nursery of Puritanism, but left it a year later on his father's death. After his marriage to Elizabeth Bourchier in 1620, he settled on his father's estate in Huntingdon, and in 1628 was elected to Parliament. He was also made a justice of the peace in 1630. Strongly inclined toward Puritanism at this time, he had a religious experience previous to 1638 which he afterward described as "being given to see the light."

When the endeavor of Charles I to rule without Parliament came to an end in 1640, Cromwell was elected as member for Cambridge. The Puritans in this Parliament outnumbered the supporters of the Established Church and the bishops, and some of the Puritans sought to replace the Episcopal Church with Presbyterianism. During the next two years Cromwell, as a leader of the Puritans, was active in condemning episcopacy and in supporting measures for the defense of "England and Ireland"—which by 1642 had come to mean the organizing of a parliamentary army against the king.

In 1642 he armed the county of Cambridge and secured it for Parliament. He then joined the army of the earl of Essex (Robert Devereux) and took part in the first important battle of the Civil War at Edgehill (Oct. 23, 1642). The following winter he built up a regiment of what he called "honest, sober Christians," and in the ensuing twenty months he was successful in a number of actions in eastern England, distinguishing himself at Marston Moor (July 2, 1644) against Prince Rupert, who is said to have first called him "ironside." He became, successively, colonel, governor of the island of Ely, acting second in command to Lord Manchester (Edward Montagu), lieutenant-general, and a member of the parliamentary Committee of Both Kingdoms.

His advocacy of toleration of the independents among the Puritans set Cromwell at odds with the Presbyterians in the army. This difference and Manchester's inactivity and hesitation, particularly in the Second Battle of Newbury (Oct. 27, 1644), resulted in debate in the Commons. Having aroused the animosity of the Presbyterians, the Scots, and the House of Lords, however, Cromwell dropped his personal quarrel with Manchester so that he might secure the passage of the Self-denying Ordinance by which members of both houses were debarred from military command.

The application of this ordinance to Cromwell himself was deferred by Parliament. He meanwhile campaigned under Sir William Waller in the West Country, under Thomas Fairfax in Oxfordshire, and on his own in the eastern counties. Rejoining Fairfax, he took part in the battles of Naseby (June 14, 1645) and Langport (July 10), and in a series of sieges in the southwest. In the spring of 1645, Fairfax sent him to report to Parliament, which rewarded him with an estate of £2,500.

Cromwell returned to the army to negotiate the surrender of Oxford (June 15, 1646), which brought the fighting to an end. The leniency of the surrender terms he proposed was subsequently criticized by both Presbyterians and extremists when Cromwell pressed for their implementation as necessary to maintain the good name of the army. He had meanwhile returned to London with his family, and he opposed vigorously in person those in Parliament who were legislating England into a Presbyterian conformity. His opponents were seemingly about to arrest him when, on June 3, 1647, he left London to rejoin the army.

The army's council of war, of which Cromwell immediately became the leader, opened negotiations with the king, and on Aug. 1, 1647, its compromise proposals for a settlement were made public. At the same time Cromwell entered London with the army and expelled eleven members of the House of Commons. Parliament then put forth its own proposals which the king refused, while still not accepting those of the army.

Cromwell persuaded Parliament to prepare fresh terms limiting the duration of the proposed Presbyterian settlement, but before these were presented, the king fled (November 11) to the Isle of Wight. It was probably this act, and the king's covert negotiations with the Scots, which decided Cromwell to reverse his policy. His endeavors to conclude an agreement with Charles at the cost of some compromise had threatened to destroy his influence with the army, and during November he and Fairfax were forced to restore discipline. He promised the troops redress of their grievances and reform of Parliament; and in January 1648 he persuaded Parliament to embark on government without the king. The two sides were again at war.

Fairfax sent Cromwell (May 1, 1648) to subdue an insurrection in Wales. As soon as this task was completed, Cromwell joined John Lambert and, at Preston, caught and defeated the Scots army under the duke of Hamilton (James Hamilton) while they were marching unguardedly to the south (Aug. 17-19, 1648).

Parliament had meanwhile repealed the vote of No Addresses to the King and negotiated the Treaty of Newport with Charles. Before Cromwell's forces could return from the north, the southern army had taken action against Parliament, and when Cromwell reached London in December, Pride's purge of 140 of the 200 members had already begun. The remainder of the Commons then moved to the trial of the king, while the council of war framed the new constitutional proposals known as the Agreement of the People. Cromwell's part in these two developments is not recorded in detail, but he seems to have regarded both as "things which God put into our hearts." When the trial of the king began, he was active in pressing it to the king's condemnation. Charles was executed on Jan. 30, 1649, and Cromwell expected that "Christians in aftertimes" would speak of it "with honour."

Cromwell's dominant position was now attacked by the extremist Levellers, and a section of the army mutinied. He and Fairfax swiftly restored order (May 1649) before he left for Ireland where the council of war sent him as lord lieutenant and commander in chief. His nine months in Ireland (August 1649 to May 1650) were intended to establish freedom of conscience and justice, as well as to promote English coloni-

zation, but his tolerance, however real for variants of Protestantism, was only nominal for Roman Catholics. The slaughter of the defenders of Drogheda and Wexford left a lasting bitterness, despite Cromwell's belief that this was "a righteous judgment of God upon these barbarous wretches."

In January 1650 Parliament had decided on Cromwell's recall, and in June it appointed him to serve under Fairfax. On Fairfax's resignation, Cromwell was named (June 26, 1650) captain general and commander in chief for the war against Scotland where Prince Charles (afterward Charles II) had been proclaimed king. Cromwell's victory against odds at Dunbar (Sept. 3, 1650) and his protestations of friendship for the Scots enabled him to secure southern Scotland by the year's end. He fell sick in the new year, however, and when he again faced the Scots they were in a prepared position near Stirling. Moving to their rear, he captured Perth on Aug. 2, 1651. Charles, meanwhile, took the opportunity to advance into England, and it was not until he reached Worcester that Cromwell was able, with the aid of the local militia, to halt and surround the Royalists and inflict the decisive defeat (Sept. 3, 1651). For his services Parliament granted him lands worth £4,000 a year and an estate at Hampton Court.

The struggles over toleration and constitutional reform were now resumed between Cromwell and Parliament until an apparent act of bad faith over an electoral bill provoked Cromwell to dissolve the Long Parliament by force (April 20, 1653). He was now the only central authority in the land. As such he, with his council, convoked a new and nominated parliament. This body produced such confusion, however, that some of its members voluntarily, and the others under threat from Cromwell's soldiers, resigned their powers again to Cromwell (Dec. 12, 1653). The council of officers then installed him (December 16) as lord protector under a newly drawn constitution which separated executive and legislative powers. He did not call another parliament for ten months, and his ordinances of this period, when he was virtual dictator, form the main part of his constructive achievement. He effected the legal union of the three kingdoms of England, Ireland, and Scotland, reorganized the church, improved the administration of justice, promoted trade, and strove to enforce a reformation of manners.

The same ten months saw the major achievements of Cromwell's foreign policy. The wars against Holland and Portugal had necessitated heavy taxation and interfered with trade. Cromwell's ideal was to build a great Protestant alliance. It was never realized, but in pursuing this aim, he successfully promoted the economic and commercial interests of Britain. He made peace with the States General (April 5, 1654), and concluded a commercial treaty with Sweden, a treaty with Denmark (Sept. 14, 1654), and a treaty with Portugal securing extraordinary liberties to English merchants.

In 1654 Cromwell convoked Parliament, but its efforts to secure a constitution giving it political and military supremacy with the power of virtual self-perpetuation, and its intolerance, caused Cromwell to dissolve it on Jan. 22, 1655. Plots against him were forestalled or suppressed in February and March and a new dictatorial rule through twelve regional commanders, called

major generals, was introduced. This provoked protests which in turn resulted in some repression.

At the same time, Anglo-Spanish hostilities in the Americas grew and spread to Europe. Cromwell prepared against the foreign threat by making commercial treaties with France (Oct. 24, 1655) and Sweden (June 1656), the latter cutting off the supply of naval stores to Spain. The threat of war and the need for additional taxes to pursue it led to the calling of another parliament in September 1656.

By now the inability to find any middle road between a dictatorial and a parliamentary tyranny was forcing both parties back toward the idea of a constitutional monarchy as a solution. On March 25, 1657, Parliament proposed, by 123 votes to 62, to invite Cromwell to accept the crown. He and the army disliked the title of king, but in accepting, with hesitation, the substance of this settlement, he secured also the confirmation of his decrees of 1654, considerable civil and religious liberties, an increase in his constitutional powers, and the right to appoint a second chamber. A fixed revenue was set aside for the armed services and Cromwell was re-installed as lord protector on June 26, 1657. In January 1658 the Commons again sought to subordinate the protector to itself and in consequence he once more dissolved Parliament on February 4.

He had meanwhile concluded a military alliance with France (March 23, 1657). Admiral Robert Blake had destroyed the Spanish Fleet at Santa Cruz (April 20), and a British agent had mediated peace between Denmark and Sweden (February 1658). With the Anglo-French victory over Spain before Dunkerque on June 4, making Dunkerque and Mardyke English possessions, Cromwell's foreign achievements reached their zenith. Although Sweden and Denmark were soon at war again and France prepared to make peace with Spain, causing the prospect of a Protestant alliance to fade, the respect for British sea power remained and British commerce expanded.

During the summer of 1658 Cromwell's health was poor. His attendance on his daughter, Elizabeth Claypole, in her last illness, increased the strain, and he fell sick and died in Whitehall on September 3. He was buried in Westminster Abbey, but after the Restoration his body was exhumed and hanged at Tyburn.

Cromwell's Puritan convictions, moral strictness, and military leadership raised him to power. He saw in his victories the approval of God. Although his rule through the major generals was despotic, and although he was responsible for the Irish's massacres and shared responsibility for the execution of the king, he nevertheless showed more magnanimity than other military dictators or than most of the Puritan Party, and his later policies, particularly overseas, were constructive. Yet after he had overturned the throne and dissolved several parliaments by force, his death found the country on the road back toward the harmony of throne and parliament in a constitutional monarchy.

R. S. MILWARD.

CROMWELL, Richard, lord protector of England: b. Huntingdon, England, Oct. 4, 1626; d. Cheshunt, Hertfordshire, July 12, 1712. The third son of Oliver Cromwell, he became his father's heir on the death of his elder brothers, Robert and Oliver. He served in the army and later was admitted to Lincoln's Inn (1647), but took no interest in government until 1654 when he stood for Parliament from Hampshire. He was elected again in 1656 from Cambridge. His father appointed him to a trade and navigation committee in 1655, but made no serious effort to bring him to the forefront until 1657 when he made him chancellor of Oxford (July) and member of the council of state (December). After his father's death on Sept. 3, 1658, he was named protector.

Unacceptable to the army and mistrusted by some of the council, he sought to appease the two, but succeeded only in increasing the dissension because of his lack of leadership. Parliament and the army finally united in agreement on his dismissal, which he accepted without protest on May 25, 1659. Fleecing his debtors, he went to France in 1660 where he assumed the name of John Clarke. He returned to England in 1680 and lived in retirement until his death.

CROMWELL, Thomas, EARL OF ESSEX, ɛs'ɛks, English statesman: b. England, ?1485; d. London, July 28, 1540. Of humble parentage, he ran afoul of the law as a young man, and in 1504 fled to Italy where he served in the French Army. He escaped from service to Florence and was befriended by Francis Frescobaldi, a banker. Going next to Flanders, he worked as a merchant's clerk in Antwerp and as a trader in Middelburg. On his return to England in 1513, he established himself as a wool merchant and moneylender, and in the latter capacity came to the attention of Cardinal Wolsey who, in 1514, made him collector of revenues for York. Cromwell's increased prominence enabled him to win election to Parliament in 1523 and admittance to Gray's Inn in 1524. Wolsey employed him as his agent in the dissolution of the small monasteries during 1525, and retained him as his secretary for the colleges at Ipswich and Oxford which were founded on the proceedings from the monasteries.

On Wolsey's downfall, Cromwell, who had already found favor with the new government of Norfolk to the extent of being returned to Parliament from Taunton in 1529, succeeded in defeating the bill of attainder against Wolsey. He also managed to be appointed to the Privy Council in 1531, and within two years became its outstanding member, being made master of the jewels and of wards in 1532, chancellor of the exchequer in 1533, and the king's secretary and master of the rolls in 1534.

He was largely responsible for the drafting of the Reformation acts between 1532 and 1539, and after his appointment as Henry VIII's vicar-general in 1535, carried into effect the Act of Supremacy and led in the suppression of the monasteries and the promulgation of the Protestant faith in England. Henry rewarded him with knighthood and made him lord privy seal and Baron Cromwell.

He was instrumental in the conviction of Anne Boleyn, negotiated a new marriage for Henry with Anne of Cleves (1539) to strengthen the Protestant union abroad, and was rewarded by being made Earl of Essex in April 1540. Henry was displeased with his marriage, however, and within two months, Cromwell was accused of treason by Norfolk before the council and sent to the Tower. He was refused a trial, and despite his aid in condemning Anne of Cleves, was convicted by a bill of attainder in Parliament and beheaded, protesting his belief in the Catholic faith.

Cromwell was a prime mover in the advancement of the Protestant Reformation in England, and the Church of England as a state-controlled institution continued to exist much as he left it. One of his significant innovations was the enactment that parish registers should be regularly kept of marriages, births, and deaths.

CRONIN, krō'nin, **Archibald Joseph**, Scottish physician and author: b. Cardross, Dumbartonshire, Scotland, July 19, 1896. He interrupted his medical studies at the University of Glasgow in 1916 to serve as a surgeon sub-lieutenant in the Royal Navy Volunteer Reserves, but returned to obtain his M.B. degree in 1919. After holding several medical positions in Glasgow, he practiced in South Wales from 1921 to 1924 when he was appointed medical inspector of mines. In 1926 he opened a private practice in London which he abandoned in 1930 because of ill-health. While recuperating, he began to write, producing a highly successful first novel, *Hatter's Castle* (1931). The two books which followed, *Three Loves* (1932) and *Grand Canary* (1933), were less well received, but the fourth, *The Stars Look Down* (1935), was widely praised. The *Citadel* (1937) was popular with the reading public but received mixed notices from the critics, as did a play, *Jupiter Laughs*, produced in London and New York City in 1940. In 1942 he scored a resounding success with *The Keys of the Kingdom*. He has since written *The Green Years* (1944), *Shannon's Way* (1948), *The Spanish Gardener* (1950), *Adventures in Two Worlds* (1952), an autobiography, and *Beyond This Place* (1953).

CRONJE, krōn-yā' **Piet Arnoldus**, South African military leader: b. within the area of the present Transvaal, Union of South Africa, about 1840; d. Klerksdorp, Transvaal, Feb. 4, 1911. His parents having migrated northward in the Great Boer Trek, he was raised under pioneering conditions and was a farmer for much of his life. He served in the Anglo-Boer War of 1880-1881, and was commander at the siege of Potchefstroom in 1881, where he forced the British garrison to surrender although an armistice had been signed some days before. Thereafter he held a number of government posts in the South African Republic (Transvaal).

On Jan. 2, 1896, at Doornkop, he captured the

Jameson raiders who had invaded the Transvaal. Later he was assigned, with the rank of general, to command in the western theater of the South African War. While besieging a British force at Kimberley, he faced a relieving division under Lord Methuen at Belmont, Graspan, and Modder River, and decisively defeated it at Magersfontein on Dec. 11, 1899. Early in the following year, another British division under Lord Roberts surrounded Cronjé and his men at Paardeberg where, after hard fighting, he surrendered on Feb. 27, 1900. He was held prisoner at Saint Helena until the conclusion of hostilities. After his release, he lived for a time in the United States and later returned to South Africa.

CRONSTADT. See KRONSTADT, USSR.

CRONSTEDT, krōōn'stēt, **BARON Axel Fredric**, Swedish mineralogist and chemist: b. Stropsta, Södermanland, Sweden, Dec. 23, 1722; d. Stockholm, Aug. 19, 1765. A councilor of mines and a member of the Academy of Sciences at Stockholm, he discovered nickel in 1751 by isolating the metal in impure form from niccolite. He introduced the use of the blowpipe in the study of minerals and was one of the first to recognize the importance of the chemical composition of minerals, using it as the basis of classification in his *Essay on Mineralogy* (1758). The mineral cronstedtite was named for him.

CRONUS, krō'nus, in Greek mythology the son of Uranus (Heaven) and Gaea (Earth), and the youngest of the Titans. At the instigation of his mother, he unmanned his father, and made himself ruler of the universe. He was the father, by Rhea, of Hestia, Demeter, Hera, Hades, Poseidon, and Zeus, who ultimately deposed him. The Romans identified him with their god Saturnus. See SATURN.

CROOK, krōōk, **George**, United States army officer: b. near Dayton, Ohio, Sept. 23, 1829; d. Chicago, Ill., March 21, 1890. After graduating from the U.S. Military Academy in 1852, he was assigned to the Pacific Northwest where he protected the settlers against Indian raids. He distinguished himself throughout the Civil War at South Mountain, Antietam, Chickamauga, and at the final battle at Appomattox. Subsequently he was reassigned to the Northwest (1866-1872), where he took part in the Sioux War of 1866, and fought against the Apaches led by Geronimo. In 1888, he was assigned to the command of the Division of the Missouri at Chicago, Ill.

CROOKED ISLAND, one of the Bahama Islands in the Atlantic Ocean, lying southeast of Florida and north of Cuba in latitude 22° 15' N., longitude 74° 13' W. A low-lying island of about 176 square miles, it has a subtropical oceanic climate with a mean annual temperature of 77° and an average rainfall of 45 inches. The chief product is salt. Pop. (1951) 1,179.

CROOKES, Sir **William**, English physicist: b. London, England, June 17, 1832; d. there, April 4, 1919. In 1854 he became superintendent of the meteorological section of the Radcliffe Observatory, Oxford, and in 1855 professor of chemistry at the Chester Training College. In 1859 he founded the *Chemical News* and after 1864,

edited the *Quarterly Journal of Science*. His own published writing in 1851 was concerned with the new compounds of the element selenium, the selenocyanides. His discovery of the element thallium was announced in 1861, and its atomic weight, in 1873. He also studied the properties of highly rarefied gases and investigated the elements of the "rare earths." In 1865 he discovered the sodium amalgamation process for separating gold and silver from their ores. He also produced diamonds artificially. He was the inventor of the radiometer (q.v.), in which a system of vanes, blackened on one side and polished on the other, begins to rotate when exposed to radiant energy. His apparatus known as Crookes Tube (q.v.) was used by Wilhelm Konrad Roentgen in the discovery of the X-ray. The experimental work which Crookes did on radiant matter changed the conception of it in both chemistry and physics. In 1900 he achieved the separation from uranium of its active transformation product, uranium-X. He published articles on spectroscopy and performed research on a great variety of other subjects.

During his lifetime Crookes received many honors and awards. In 1881 he was given the medal of the Universal Exposition in Paris. He was knighted by the British Empire in 1897 and received the Order of Merit in 1910. The Albert Gold Medal was awarded him in 1899 and the gold medal of the Society of Chemical Industry in 1912. At various times between 1908 and 1912 he was president of the Chemical Society, the British Association, and the Institute of Electrical Engineers, and was a member of many scientific institutions throughout the world. Included among his published writings are *Select Methods in Chemical Analysis* (1871) and *Diamonds* (1909).

Consult Fournier d'Albe, E. E., *Life of Sir William Crookes* (London 1923).

CROOKES TUBE, a tube invented by Sir William Crookes (q.v.) and used about 1875 for his research on electrical discharges in gases. In the vacuum tubes which he used the pressure was reduced to the point that the bright glow observed at high pressures almost disappeared. Obstructed by very little residual gas, the cathode rays shot straight across the tube and, striking upon the opposite glass wall, caused it to glow with greenish fluorescence. By placing an obstacle like a metal plate in the path of the rays, Crookes was able to show their rectilinear character by the shadow on the fluorescing surface. In another tube he interposed a light paddle wheel with metallic vanes in the ray's path and found the wheel driven with considerable speed. Thus he demonstrated that cathode rays produced fluorescence, traveled in straight lines, were deflected by a magnetic field, carried momentum, and transmitted energy.

CROOKSTON, krōōk'stūn, city, Minnesota, seat of Polk County, at an altitude of 863 feet, on the Red Lake River, and served by the Great Northern and Northern Pacific railways. Crookston is 300 miles northwest of St. Paul and Minneapolis on federal highways, in a fertile agricultural region. It ships wheat, livestock, dairy products, sugar beets, and potatoes. Power for the city is furnished by a lignite-burning steam plant. The city manufactures lumber, farm machinery, sashes and doors, and processes dehy-

drated alfalfa, certified seed potatoes, sugar beets, beans and peas. The Red River Valley winter show of livestock and farm products is held at Crookston annually. It has the Northwest School of Agriculture, a branch of the University of Minnesota; the Northwest Agricultural Experiment Station; and St. Joseph's Academy. First settled in 1870 by Col. William Crookes, it became a borough in 1878, and a city in 1882. It is governed by a mayor and a council of nine members. Pop. (1950) 7,352.

CROP. See AGRICULTURE IN THE UNITED STATES.

CROP INSURANCE. In general terms, crop insurance indemnifies against loss or damage from a variety of causes beyond the control of the insured; these causes may be divided broadly into weather hazards and pestilence hazards. In practice, the insurance has been written at one time or another in various ways: against all risks or against specified perils; by private insurers or by government agencies; and covering many kinds of crops, or restricted to one or to a few.

In the early years of underwriting this class of insurance, much experience was acquired by trial and error. In 1899, for example, a company issued a policy under which it agreed to purchase the entire crop insured at \$5 per acre at the option of the insured to be exercised not later than five days after threshing. The contract provided insurance against the hazards of weather and pestilence as well as that of price decline. As the valued amount proved to be at variance with the farmer's normal value output, and the premium charge, 5 per cent, inadequate, the insurer withdrew at the end of the season with a heavy loss. Another venture was undertaken in 1917 by two companies, each offering a broad coverage, for losses up to \$7 per acre at a 10 per cent premium; again both suffered loss and withdrew from this field. Three years later an insurer issued a policy on a cost-of-production basis. The insured was asked to list expenses per acre for such items as plowing, harrowing, rolling, seed, seeding, harvesting and threshing, including estimated rental value. A conservative percentage of this total was taken as the amount of insurance for which a 6 per cent premium was charged. All of the major hazards except hail were covered, and in addition, if for any reason the crop was physically damaged, the policy covered the hazard of a market decline. The drop in prices in the fall of 1920 made the results disastrous for the company. The following year the same company adopted a different basis; namely, the indemnity was measured from either a stated value per acre or a stated number of bushels per acre, the company reserving the right to choose the method. Only a small amount of insurance was placed and again it proved expensive. After 1921 no further attempts with broad coverage on basic crops were made by private insurers, though a few policies covering frost were placed at various times on citrus fruit and some with broader coverage on truck gardening, neither of which proved profitable.

Private Hail Insurance.—In coverage against the single peril of hail, private insurers have been writing insurance for a number of years. The business is written by both stock and mutual carriers. Originally confined to the grain-producing states between the Mississippi and the

Rockies, this type of crop insurance was written in the United States first in 1883. By 1914 approximately 16 stock fire insurance companies were in the field, and between that date and 1945 some 150 such companies wrote hail insurance from time to time; in the latter year the number was about 90. Their experience was checkered, with a loss ratio as high as 122 per cent in 1915; even in 1944, when the total net premiums amounted to over \$29,900,000, the ratio was 67 per cent caused by an unusual frequency of severe hailstorms in almost all states.

Attempts to improve loss ratios have been made, along with other ways, through employing practical agriculturists to gather information and statistics in order to establish adequate rates and improve policy forms; moreover, by 1936 several of the larger companies had extended operations to those states where cotton and tobacco are the primary crops, and a considerable volume was written also on tree fruits and truck crops, thus giving them a better spread and a more balanced income. A strong factor in the development of hail insurance has been provided by the Western Hail and Adjustment Association, a voluntary cooperative organization formed in 1915 by the hail-writing companies for compiling statistics under 64 crop classifications and as a clearing house for ideas, advisory rates, rules and forms.

As currently written (1946) hail insurance covers only the peril of hail damage to growing crops, commercially grown, except that wind damage accompanied by hail is covered on tobacco only. The list of crops that may be insured is a broad one, including—in addition to tobacco—cotton, bush and tree fruits (not the trees), vine fruits and vegetables, flax and the various grains.

Rates are established from the experience statistics of the companies, and vary in different localities and according to the susceptibility of the crop. Adjusted each year, they range from 3 or 4 per cent to as high as 15 or 20 per cent. Within stated limits per acre the farmer may insure his crop up to its full value.

As the hail insurance is seasonable and does not carry over from year to year, the private insurer sets up no reserve. Some companies, however, fix their own liability for each township, and when the maximum is reached, no further commitment is accepted for that township. Coverage may be placed by the farmer at any time from planting or sowing to harvesting, but the rate for the season is the same, regardless of the date of the application; he may increase the amount of insurance as the season advances.

In addition to the annual form of policy, a five-season form with guaranteed price per bushel is available. Its terms are essentially the same as those of the annual form, and it is written on a per bushel per acre basis instead of only an acre basis. There are also other variations.

State Hail Insurance.—A number of states at various times have provided hail insurance on specified crops. Those now doing so (1946) are North Dakota, where the State Hail Insurance Department began to function in 1919, some protection having been written under other departments as early as 1911; Montana, which has been offering this coverage through the State Board of Hail Insurance since 1917; and Colorado, through the State Hail Insurance Department since 1929. The grains, predominantly wheat followed by barley and oats, are the chief crops

insured in these states; coverage is provided in North Dakota also for flax, cane, and certain forage plants, while Montana includes also beans, peas, sugar beets, potatoes, mustard and alfalfa seed, and Colorado beans, beets, alfalfa and feed crops, and mixed vegetables. The limits of coverage vary: in North Dakota a farmer has the option of applying for \$5 or \$8 per acre; in Montana he may insure up to amounts ranging from \$8 to \$20 according to crop; and in Colorado up to the average value per acre of the crop with maxima fixed from \$7 to \$25 and an overall limit of \$2,500 for any person in one section. Rates depend on locality and on loss experience.

Though differing in detail, the basic plan in these states is to levy a tax on the lands insured sufficient to pay the indemnities and operating expenses, variations being that for certain special policies, North Dakota receives cash premiums, and Montana in 1946 allowed a 4 per cent discount for cash. In 1945 North Dakota paid approximately 25 per cent of the loss in the form of tax reduction and Colorado approximately 29 per cent; in the latter case the percentage was calculated on the basis of 80 per cent of the gross adjusted loss, that being the amount paid the insureds, for the law permits the board to prorate the indemnities in any year when the total losses exceed the estimated receipts available for payment of losses, plus the reserve. North Dakota made a net operating profit in 1945 of \$45,660, bringing the net total profit from 1919 through 1945 to \$872,592; at the close of the same year, Montana had about \$40,000 in the hail insurance fund for use in the 1946 season. The figures below show a summary of the 1945 business.

	North Dakota	Montana	Colorado
Total risk written	\$13,532,515	\$4,571,798	\$1,063,236
Premium (tax and cash)	925,550	392,132	109,264
Acres insured	1,757,886	541,998	152,945
Losses paid or adjusted	648,143	301,263	92,203 ¹
Loss ratio	4.79%	6.6%	8.68%
Operating expense ratio	11.11%	3.6%	12.26%

¹ Gross, before calculation of 80 per cent.

Federal Crop Insurance.—Crop insurance by the federal government was instituted by the Federal Crop Insurance Act (1938). It provided for the creation of the Federal Crop Insurance Corporation under the Department of Agriculture, and a capital reserve of \$20,000,000 was set up. Field administration and supervision are delegated to state and county committees of the Agricultural Adjustment Agency (AAA). It is a nonprofit program, with the government defraying all administrative costs.

Coverage is against all risks of unforeseen physical hazards, including hail, snow, excessive rain, lightning, wind, fire, drought, frost, flood, winterkill, insects, disease, and wildlife; the hazard of market price decline is avoided by providing that premium payments be calculated in bushels or pounds of the commodity insured, which need not be paid generally till about harvest time in the area, and that indemnities be paid in the same medium, that is, by certificates for the number of bushels or pounds due the insured, who may obtain their cash value from the corporation. The insurance is by farm rather than by acre. The protection is against loss of yield up to 50 or 75 per cent, at the option of

the farmer, of the average yield for the insured farm; under a trial insurance program, however, insurance against loss of investment, not to exceed 75 per cent of the investment in the crop, also is being written. Applications must be made before seeding or planting and before a closing date established for each crop. In general, a uniform rate per acre is charged for all farms in a county. Wheat is insured under contracts covering three consecutive crop years, flax on an annual basis, and cotton under a contract automatically continuing from year to year.

Federal crop insurance is not intended to take the place of insurance by private carriers. Rather does each supplement the other. Federal insurance is not designed to cover small, partial, or total losses on a part of the acreage, referred to as spot losses, against which the farmer can get 100 per cent protection through the usual insurance channels. Moreover, private insurers of hail perils do not regard federal crop insurance as contributory insurance even though the damage causing the loss might be entirely from hail; the farmer can collect from both, the only exception being that in the case of loss by fire there is reduction in federal insurance for other insurance. In the words of one of the officials of the corporation, federal crop insurance "is fundamentally for the purpose of creating catastrophe insurance and is intended to insure a minimum return to the farmer which will enable him to stay in business in case of severe loss. . . . The justification for this government insurance is not alone the need of protection of the individual farmer from the great losses which continually threaten him, but also of the welfare of those dependent upon products of the farmer and his continued income and buying power. This affects vitally alike labor, industry, trade, banking and the entire community of which the farmer is a part."

Wheat was insured during the years 1939–1943 and cotton during 1942 and 1943. In each year indemnities exceeded premiums for both commodities, the loss to the corporation running to more than \$37,000,000 for the five-year period. In the 1944 and 1945 Agricultural Appropriation acts, Congress provided funds only for liquidating the insurance on the 1943 and earlier crops, with the result that no federal crop insurance was placed on crops planted in 1944. However, the program was revived by an amendment to the Federal Crop Insurance Act and by the Agricultural Appropriation Act (Dec. 23, 1944). This amendment made changes from the previous program, designed to eliminate such deficits from future operations so that premiums should cover fully the average losses and contribute in favorable years to a reasonable surplus to offset possible extraordinary losses or catastrophes.

In order to strengthen the program and to bring crop insurance to a larger number of farmers the amendment provided for coverage of more crops. Flax was added as a regularly insurable commodity, and a progressive plan was instituted for new experimental crops, this trial insurance being limited on each commodity to a period of three years and to 20 counties. Corn and tobacco were selected for this trial insurance in 1945. No additional trial crops were added in 1946, but early in that year the corporation announced that in 1947, insurance would be extended on a trial basis to citrus fruits, potatoes, and peanuts.

Insurance was limited in 1945 to spring-planted crops because the 1944 fall-planted crops, such as winter wheat, were planted before the amendment was passed. The 1945 insurance covered 23,400 wheat farms (spring wheat), 113,000 cotton farms, 38,000 flax farms, 13,400 corn farms, and 13,200 tobacco farms, in 33 states. Applications, including those on 1946 winter wheat, were written in 1945 covering more than 540,000 farms

WOODHULL HAY,

Educational Editor, "The Weekly Underwriter."

CROPSEY, krōp'si, **Jaspar Francis**, American painter: b. Rossville, N. Y., Feb. 18, 1823; d. Hastings-on-Hudson, N. Y., June 22, 1900. For five years he studied architecture with a successful firm, and one of the outstanding jobs of his career was designing and superintending the building of the former Sixth Avenue Elevated Railroad stations for New York City. His landscape paintings brought him more distinction. He lived and studied in several European countries and is represented in the Metropolitan Museum, the Corcoran Gallery, and many private collections in the United States and Europe. His paintings include: *Old Mill, Battle of Gettysburg, Greenwood Lake, and Autumn on the Hudson River*. He helped to found the American Water-Color Society and was a member of the Artists Aid Society and the Society of Science, Letters and Arts of London.

CROQUET, krō-kā', an outdoor game played with balls, mallets, and arches, upon a court of either closely mowed grass or clay or loam soil. France introduced the game into Ireland and England early in the 17th century. Originally called Paille-Maille, meaning ball-mallet, by the French, it was anglicized as Pall Mall and gave the name to a famous street in London. After being largely neglected in the 18th century, croquet again came into vogue about 1850 (when it was first played in the United States) but ultimately was superseded in popularity by tennis. When first introduced it was a simple game with little opportunity for skill but was developed by experts until it can be as scientific as billiards.

In the United States croquet is played unprofessionally upon a level, rectangular court, often about 40 by 60 feet, although its size may vary. A wooden stake is placed at either end of the court on an imaginary straight line, at least six feet from the end lines and midway between the side lines. The nine steel wickets are placed in the following manner: Wicket 1 is two complete mallet lengths from the home stake; Wicket 2 is directly in front of and one mallet length from Wicket 1; wickets 3 and 9 are set on a line at right angles to the imaginary line from stake to stake, as are wickets 5 and 8 (3 and 9 being on a line midway between 2 and 4, while 5 and 8 are on a line midway between 4 and 6); wickets 7 and 6 are set in front of the second stake, in positions exactly similar to 1 and 2 at home stake; Wicket 4 is in the center of the court, through which the balls pass on leaving wickets 3 and 8, and a variation is to use double wickets, proving a much greater obstacle.

The balls for the game are made of either wood or vulcanized rubber, approximately 3¾ inches in diameter. A colored strip on each ball is used for identification. Mallets vary in size and weight. There are nine steel wickets (10

for the purpose of testing his veracity, explaining or modifying his testimony, or developing facts in a light favorable to the cross-examiner. In general, a person against whom a witness is called, in either a civil or a criminal case, has the absolute right to cross-examine. A person testifying in his own behalf can be cross-examined by his adversary; and a defendant in a criminal prosecution who testifies for himself thereby subjects himself to cross-examination, which he cannot prevent by claiming the constitutional privilege against self-incrimination. Although cross-examination must be confined to the issues being litigated, its extent is largely discretionary with the trial judge, and the reviewing court will not interfere except in a case of clear abuse of discretion.

RICHARD L. HIRSHBERG.

CROSS-FERTILIZATION, the combining of the heredities of different individuals by means of the union of their sex cells. This process of sexual union or cross-fertilization is the prevailing method of reproduction in nearly all animals and in many plants. The tremendous emphasis on sex and cross-fertilization in the animal and plant kingdoms has been noted by human observers since the beginning of time, and has constituted one of the outstanding problems of science. The various attempts to explain the biological significance of cross-fertilization made prior to the rise of modern genetics in the 20th century, however, were all erroneous in greater or lesser degree. The age-old problem of the reason for the existence of sexuality and cross-fertilization was finally solved in recent times by the science of genetics.

Sex and Reproduction.—It is frequently assumed that sexual union is necessary for reproduction. It is a fact that sex and reproduction are inseparably linked in higher animals. But higher animals have evolved from simple unicellular animals in which the two processes are distinct and even antagonistic. Reproduction in a single-celled protozoan is achieved by fission. One cell splits into two. Sexuality in such organisms is expressed by the conjugation of cells. Two cells become one. The whole life cycle of a typical protozoan consists of alternative phases: division of the cells leading to an increase in the numbers of individuals and hence in the reproduction of the population, and sexual conjugation between different cells resulting in a decrease in the number of individuals. Even in higher animals the basic antagonism between sex and reproduction persists, though in covert form, and thus reveals the essential and original distinctness of these two biological processes. Sexuality in the higher forms of life means that two individuals are required in order to carry out a process of reproduction which, in the absence of that factor, one individual alone might conceivably accomplish by some form of budding or splitting.

The importance of reproduction is obvious enough. It is the indispensable condition of perpetuation of the species over a period of time. But what important function is performed by sex and cross-fertilization which can account for its establishment in the life cycle even though it reduces the reproductive efficiency of the species?

Gametes.—Cross-fertilization, whether in a protozoan, worm, flowering-plant or mammal, is essentially the physical union of the gametes or sex cells produced by different individuals. These

gametes, which are usually microscopic in size form the only connecting link between generations of sexually reproducing organisms. The largest animals of sea and land and the tallest trees of the forest develop from microscopic eggs fertilized by even tinier sperm. It has been calculated that all the human beings on earth today have developed from two gallons of egg cells fertilized by a quantity of sperm cells equal in volume to a tack head. The eggs are immobile cells provisioned with food reserves, the sperm are small actively swimming cells. The important materials in the gametes, which comprises the physical basis of all heredity, is known as the germ plasma.

Genes.—The germ plasma consists of numerous protein molecules of great complexity and specificity which possess the remarkable capacity for self-duplication. These are the hereditary factors or genes. Most of the genes are borne in chains on long thread-like structures—the chromosomes, which are contained in a central nucleus in each cell of the body. Some genes apparently reside in the protoplasm outside the nucleus. The genes, in interaction with the environment, control the course of development of the organism, and hence the characteristics of the mature individuals. All the hereditary potentialities of an individual, whether it will develop to a large or a small size, have blue or brown eyes, thrive best in a warm or a cold or a dry climate, etc., are determined by the genes it acquires at fertilization, when the gametes unite.

The number of genes represented in an individual may be reckoned in the thousands. Rough estimates for the small vinegar fly, *Drosophila*, suggest that at least 5,000 or 6,000 kinds of genes, and perhaps many more, are present in this organism. Many of the genes, moreover, are represented in different forms, or alleles. In man, for example, the gene for eye color is represented by alleles for blue eyes and other allele for brown eyes. A whole series of alleles is known for the eye color gene in *Drosophila*, giving eyes of various hues of red, buff, or white. The different hair colors seen in man or other mammals, the different body colors in *Drosophila*, the different flower colors in many garden plants are often due to the expression of different alleles of some gene which controls this trait. In now, an individual with red flowers, or gray fur or red eyes crosses with an individual with white flowers, or white fur, or white eyes, the offspring of this union will have received different alleles of these genes from the two parents. The combination of different alleles in one individual may lead to some new or different expression of the gene involved. The first generation progeny of a cross between individuals differing with respect to the alleles of a certain gene-pair may be intermediate in the character in question or, more commonly, may approach the condition found in one or the other parent.

It will ordinarily happen that the two individuals which cross will differ with respect to many genes. Gregor Mendel, the father of modern genetics, crossed a pea plant with yellow round seeds by an individual with green wrinkled peas. The color and surface character of the seeds are controlled by separate pairs of genes. In the second generation derived from this cross Mendel obtained some individuals like the first parental type, other individuals like the second parent, and in addition some plants unlike either parent in that their seeds were either yellow

and wrinkled or green and round. The latter two classes of progeny are called the recombination types because they exhibit new combinations of the genes passed on to them by their original parents. *Cross-fertilization is a mechanism for bringing about the recombination of genes.* See also POLLINATION; PLANTS AND PLANT SCIENCE —Plant Breeding, Genetics, and Cytogenetics.

Adaptation.—It is becoming increasingly clear from experimental studies that natural selection, which favors the better adapted individuals in the struggle for existence, operates not so much on single characters as on character combinations. Adaptation of organisms to their environments involves whole ensembles of characteristics. In mankind, for example, the traits of brown skin, dark hair, and brown eyes seem to be adaptively superior in tropical climates, whereas the alternative combination of blond skin, hair, and eyes appears to be better fitted

Fig. 1. The appearance of recombination types in the second generation progeny of the cross of a yellow round by a green wrinkled pea

for human inhabitants of northern forest environments. The races of man which occupy respectively the contrasting environments have come to differ in the whole character complex.

Less familiar but better founded examples of the importance of character combinations for adaptation occur among many other species which have been analyzed by naturalists and geneticists. The black mustard, *Brassica nigra*, is a weed of widespread occurrence in Asia Minor. One race of this species has become specialized as a weed in fields of the cultivated yellow mustard. It differs from the less specialized races of the same species in at least eight separate characters involving habit of branching, height of stem, size of flowers and of seeds, and time of flowering. A close analysis of these differences reveals that they all help the black mustard to mimic the cultivated yellow mustard. The success of the former as a weed in fields of the latter is due to the fact that it grows and ripens simultaneously

with the cultivated plant and is harvested, threshed, and dispersed with it. Its adaptation is based not on any one single feature but on a set of characters.

Let us imagine a population of animals or plants with a set of five characteristics symbolized by $A B C D E$. The letters also symbolize the genes which determine these different characters. Now, the character combination $A B C D E$ was advantageous in the environment formerly inhabited by this population. But the climate has changed during the course of time; new environmental conditions were established for which the combination $A B C D E$ is no longer well adapted. Adaptation of the organism to its new circumstances can be secured by the combination of characters $a b c d e$. To succeed in this new environment the genes $A B C D E$ must be replaced in the population by a new set of alleles $a b c d e$.

Mutation and Recombination.—There are two ways in which a set of genes can be assembled in an individual. The first and least efficient is the mutation or permanent and hereditary change of the genes from one allelic form to another. Gene mutations do occur spontaneously in nature as relatively rare events in the life of every kind of organism. The gene B may mutate to b once in 100,000 generations. The new individual is then $A b C D E$. But since adaptation involves the whole gene complex, this mutant individual is little or no better adapted to the new environment than its predecessors. Meanwhile, another individual in the population has acquired a mutation in gene D to the allele d . Its constitution $A B C d E$ does not fulfill the requirements for adaptation to the new conditions either. The chances of a series of simultaneous or successive mutations of all five genes occurring in one individual or one immediate line of descent, to give the new combination $a b c d e$, are infinitesimally slight. For most kinds of animals and plants the probability of a new and adaptive combination of five genes becoming assembled in one individual as a result of chance mutations alone is so small that this event is unlikely to occur even once during the whole evolutionary history of the species. When we consider that most adaptations in nature are far more complex than our hypothetical case, in that the interaction of many more than five genes is necessary in order to attain them, we can gain some appreciation of the limitations of the mutation process by itself as a method of assembling desirable new gene combinations.

If, however, the various mutant individuals can cross sexually, they can pool the mutations which they have individually acquired and produce the new recombination type directly. Cross-fertilization of the two individuals $A b C D E$ and $A B C d E$ will give several classes of offspring among which are individuals of the constitution $A b C d E$. Other individuals in the population representing the mutant types $a B C D E$, $A B c D E$, and $A B C D e$, may intercross with one another and with the first two mutants. Such crossing will lead to the reshuffling of the genes; various new recombination types, including the desirable one, $a b c d e$, will emerge out of the shuffle. The combination of mutant genes which could not be assembled by the mere chance of simultaneous multiple mutations once in millions of generations is readily brought together in a few generations by means of crossing between the various mutant types.

Herein lies the great role in nature of sex and cross-fertilization.

The Breeding Population.—Individuals of a cross-fertilizing species are tied together in interbreeding populations by bonds of mating and parenthood. The population may be enormously large in the case of an extensive forest of pine trees or the erstwhile bands of passenger pigeons; it may be a small-sized colony numbering only a few hundred breeding individuals in a grove of Monterey cypress or the semi-isolated breeding colonies of geese. Whether small, large, or medium-sized, the population represents an accumulation of hereditary variations, a pool of genes, which is shared by the individuals constituting the population. Such a population is a dynamic entity. Cross-fertilization is constantly bringing about new combinations of the various gene alleles. Many of the character combinations produced by the novel gene recombinations are poorly fitted for the existing environment and are rejected by natural selection: the individuals possessing an unadaptive genetic constitution contribute less than an average number of descendants like themselves to the next generation. Other new recombination types generated by cross-fertilization may represent improvements upon the average level of adaptation of the population to its surroundings; such gene combinations will tend to be perpetuated by natural selection. The frequency of certain gene alleles in the gene pool will thus increase while the frequency of other alleles decreases.

Self-fertilizing or asexual organisms cannot form interbreeding communities of this sort. The integration brought about by mating bonds, and the evolutionary advantages arising from the sharing in a common gene pool, are impossible in sexless forms of life. Such organisms form aggregations of asexually reproducing individuals, called clones, each one of which stands alone with respect to the generation of new hereditary variations.

It is not difficult to understand why most contemporary species of animals and plants, the present-day representatives of the successful lines of evolution, reproduce by means of cross-fertilization. As stated by the geneticist Hermann J. Muller: "There is no basic biological reason why reproduction, variation, and evolution can not go on indefinitely without sexuality or sex; therefore sex is not, in an absolute sense, a necessity, it is a 'luxury.' It is, however, highly desirable and useful, and so it becomes necessary in a relativistic sense, when our competitor-species are also endowed with sex, for sexless beings, although often at a temporary advantage, can not keep up the pace set by sexual beings in the evolutionary race, and when readjustments are called for, they must eventually lose out."

Systems which Promote Outbreeding.—Cross-fertilization is brought about in the vertebrate animals, the insects and other arthropods, and some kinds of seed plants (cycads, junipers, willows, hemp, some palms, etc.), by the simple device of dividing the breeding population up into two kinds of individuals, males and females, neither one of which is alone sufficient for reproduction of the species. The original meaning of the word sex, derived from the Latin root *seco*, to cut, refers to the division into male and female forms. From the standpoint of a geneticist, the presence of males and females is superstructure. What is essential about sexuality is not the sub-

division of the population into different kinds of individuals, but the combination of different heredities which this arrangement accomplishes.

Most flowering plants and some animals such as snails, worms, and sea squirts are hermaphroditic. A single individual possesses both male and female organs. Self-fertilization may be prevented, however, by various devices, both mechanical and physiological. The stamens (male parts) and carpels (female parts) of a flower may ripen at different times. These organs may be of different lengths or so disposed in the flower that they do not normally come into contact (see FLOWERS). The female organ in snails and worms is normally inaccessible to the sperm of the same individual. Copulation is consequently a mutual affair in which two individuals exchange sperm. Furthermore, the male and female gametes produced by the same individual may be incompatible and fail to effect fertilization even if they do meet. Self-incompatibility, the obstruction of self-fertilization by physiological blocks, occurs in the sea squirt *Ciona* and in numerous plants.

Specific genes are known in a number of flowering plants which cause a failure of pollen tube growth in the styles of the same individual. The self-incompatibility gene, *S*, is represented in the population by a series of

Fig. 2. Mating of two earthworms. In this hermaphroditic organism each individual bears both male and female sex organs on its lower side. During copulation two worms stretch out with their ventral surfaces in contact, their heads pointing in opposite directions, and exchange masses of sperms.

alleles, $S_1, S_2, S_3, \dots, S_n$. Fifteen alleles of the *S* gene have been found in tobacco, 37 in the evening primrose, 40 in red clover, and it is probable that the total number of alleles within any one self-incompatible species may be reckoned in the hundreds. An individual possessing the alleles S_1 and S_2 (written S_1/S_2 in the shorthand of genetics; two alleles of each gene are present in the body cells of higher plants and animals) will not set seeds either with its own pollen or with that of any other S_n/S_m individual. All the S_n/S_m individuals in the population thus form an incompatibility type; selfing or interbreeding among the members of the group is opposed by the incompatibility gene, but the members can cross freely with individuals belonging to any other incompatibility group. Owing to the large number of alleles of the *S* gene, scores or hundreds of such incompatibility groups are present in the population. The promotion of outbreeding, which is accomplished by the sexes in bisexual animals and plants, is carried out by the incompatibility types of hermaphroditic organisms.

Among the protozoans, bacteria, and many algae and fungi there is no recognizable differentiation of the gametes into sperm and eggs. The gametes, as observed under the microscope, are identical in appearance. They may be produced in special organs, which, however, are not dif-

ferentiated into male and female; or, in the unicellular forms, the gametes which unite at fertilization may be the whole individual organisms. In any case, a morphological distinction between male and female gametes, sex organs or individuals is not discernible. Nevertheless, the gametes and the organs and individuals which release them are not all entirely alike physiologically. This is indicated by the fact that cross-fertilization can be successfully accomplished by certain combinations of individuals and not by others. Systematic breeding tests show that the population is composed of different mating types, similar to the incompatibility groups found in many flowering plants. The commonest situation is perhaps the separation of the population in just two mating types, usually labelled the plus and minus strains, between which crossing can take place. More than two mating types exist in certain fungi. The existence of two or more mating types obviously brings about outcrossing in the microorganisms.

Asexual Reproduction.—Cross-fertilization is the only means of reproduction among the mammals, birds, reptiles, amphibians, fish, and most insects. In many other kinds of living beings the

Fig. 3. Petri dish cultures of the different combinations of two strains of a mold. The combination of a plus and a minus strain leads to cross-fertilization and the formation of black fusion cells along the line of contact, whereas two like strains of mold come into contact without interbreeding.

sexual process is supplemented by some asexual method of propagation. Many perennial plants reproduce sexually by seeds and in addition spread vegetatively by creeping stems (for example, strawberries), underground rhizomes (iris), stump sprouts (poplar), or the like. Most of the multiplication of aphids throughout the summer is by asexual means. The females are specialized for giving birth to living young parthenogenetically; their eggs develop without fertilization by sperm. At the end of summer, however, a sexual generation is produced, and the eggs which are laid to overwinter are the products of cross-fertilization. Asexual reproduction by fission alternates with periods of cross-fertilization and gene exchange in unicellular organisms such as protozoans, the simplest algae, and some bacteria.

The potentiality for self-fertilization exists in all hermaphroditic organisms and is actually realized in a great many cases. Not all hermaphrodites possess those mechanical or physiological barriers which make outcrossing obligatory. Some hermaphroditic pond snails, for example, regularly reproduce by self-fertilization. Self-fertilization is the rule in many cultivated plants,

such as tomatoes, peas, wheat, and barley, and in many species of annual wild flowers.

Furthermore, many kinds of organisms derived from sexual and cross-fertilizing ancestors have given up sexuality and currently reproduce entirely by asexual means. This is the case in the common dandelion and blue-grass among flowering plants, and in the great group of Fungi Imperfecti. In certain brine shrimps, grasshoppers, moths, weevils, and earthworms the females produce eggs which develop parthenogenetically, without fertilization, into new individuals.

Fitness and Flexibility.—The diversity of breeding systems in the living world is at first sight a source of perplexity. A theory has recently been advanced by comparative geneticists which attempts to simplify and unify the great variety of reproductive systems by expressing them as different permutations of two common elements. The two elements pervading all types of life cycles are fitness and flexibility. Each one of these two qualities is indispensable for a successful species. Without fitness, the adaptation to its immediate surroundings, the organism cannot begin to survive. It is equally necessary for its survival that it be capable of responding by genetic variations to the inevitable changes in its environment. It must be flexible as well as fit in this world of change.

Fitness, once built up by crossing and gene recombination in interaction with natural selection, can also be broken down by the same sexual process. Cross-fertilization can bring together an adaptive gene combination; it can also break it apart. But the adaptive gene combination can be preserved and passed on intact to future generations if the sexual process is circumvented by self-fertilization or some kind of asexual multiplication. The circumvention of cross-fertilization may not be an unmixed blessing, however, for while it preserves the integrity of an existing gene combination, it also prevents the formation of new and possibly better combinations. The sacrifice of long-range flexibility in the interest of immediate fitness may be disadvantageous in the long run, particularly if the environmental conditions should shift away from the older adaptive combination. The history of life is full of examples of species which have become invariable and stereotyped and therefore have been restricted to small relictual areas or exterminated altogether.

The breeding system of each species represents a compromise between immediate fitness and long-range flexibility. This compromise is manifested in the relative roles which sexual and asexual processes play in reproduction. Cross-fertilization, as the main source of flexibility, must strike a balance with self-fertilization and asexual multiplication, as the means of preserving fitness in the interest of the successful functioning of the organism. The happy medium between fitness and flexibility is not necessarily the same for all kinds of organisms or at all times in their life histories.

Aphids to expand their populations on plant leaves during the summer months, bacteria to multiply in a favorable medium, irises or strawberries to spread over a spot of ground, many annual wild flowers to produce an abundant crop of seeds during their single season of growth may be best served by an ability to reproduce rapidly without the agency of cross-fertilization. In this way a gene combination,

the fitness of which has already been tested and passed upon by natural selection, can be rapidly multiplied and passed on to the hundreds, thousands, or millions of individuals who will colonize and exploit some available habitat. The relatively slight amount of flexibility which is necessary for the maintenance of a high adaptive level in the face of environmental changes may be secured in such organisms by occasional periods of crossing and gene exchange.

The equilibrium point between optimum flexibility and fitness lies much more on the side of gene recombination in the case of the dominant trees of the forest, the dominant bunch grasses and perennial herbs of the steppe, and the shrubs of the deserts and brushlands. Competition for Lebensraum is strong, and the race goes to the seedling with the best adapted gene combination in each particular site. Cross-fertilization is the predominant or even the sole method of reproduction in such types of plants. An even greater emphasis on gene recombination, as compared with asexual methods of propagation, is found in the higher animals, both vertebrate and invertebrate. The enormous complexity of the body of such organisms and the corresponding complexity of the relations between the organism and environment do not allow of one simple genetic formula for fitness, which can be multiplied indefinitely by asexual means. In fact, the power of asexual reproduction is wanting entirely among the majority of the higher animals, with the exception of a limited ability to regenerate lost parts belonging to individual bodies. Reproduction in higher animals is, with rare exceptions, synonymous with cross-fertilization.

CROSSBREEDING AND INBREEDING

It has been known for a long time that certain general rules apply to crossbreeding and inbreeding, although these rules have many exceptions. They are: (1) inbreeding tends to make a stock more homogeneous, and may lead to a decline in vigor; (2) crossbreeding increases the variability of a stock, and often leads to an increase in vigor. Both of these rules can now be explained on the basis of the Mendelian theory of inheritance.

According to Gregor Mendel's theory, which since its rediscovery in 1900 has been thoroughly substantiated experimentally, characters of animals and plants are determined by the units of heredity called genes, and each individual possesses two genes (not necessarily exactly alike) of each kind, one from his father and one from his mother, and he transmits one of each pair to each of his descendants. From this simple fact it can be shown mathematically that if close relatives mate, the offspring will tend on the whole to have both members of each gene pair exactly alike, and will resemble each other, as a result, more closely than would the offspring of random

matings. After a certain number of generations of inbreeding no more individuals with unlike pairs of genes (heterozygotes) will be found, all individuals produced will now have like genes in each pair (will be homozygous), although these pairs may be of either kind. The variability of an inbred population is thus decreased. This prediction has been fully verified by experiment (for example, Sewall Wright's work, 1922 and 1929).

Crossbreeding increases to a maximum the number of individuals having the different members of the various pairs of genes unlike each other. This makes the variability of the stock as great as is consistent with its supply of genetic material. In addition, crosses often display what is known as hybrid vigor. An example of hybrid vigor is the mule, a cross between two different species, the horse and the ass. The mule is larger and stronger than the ass, has much the same strength and speed as the horse and possesses also the sure-footedness, endurance, and lack of excitability of the ass.

The explanation of the decrease in vigor resulting from inbreeding is that in general genes are of two kinds, dominant and recessive, and the latter do not manifest their effects in an individual who possesses also a paired dominant gene. Many of the recessive genes are deleterious, but do not produce their effects in the heterozygotes. Inbreeding brings them together in the resulting homozygotes, and such homozygous recessive individuals are inferior. Conversely, crossbreeding, by reducing the numbers of such homozygous individuals to a minimum, improves the stock (at least temporarily). Some of the genes which influence vigor may exist in homozygous form (each member of a gene pair just like the other) in pure inbred stocks, and cross fertilization may result in the production of heterozygous individuals in which most of the pairs of genes influencing vigor contain one of the dominant genes which make for greater vigor. This phenomenon is made use of commercially in the production of hybrid corn, where inbred strains of corn, free from abnormalities but distinctly unimpressive to look at, are crossed to produce large vigorous plants with high yield.

Inbreeding is not a disadvantage, even in the absence of selection, in a stock free from undesirable recessive genes, and it has been practiced in certain instances in man without bad effects, as in the brother-sister matings in the royal families of Ancient Egypt. Inbreeding is useful in eliminating defects, if coupled with a high degree of selection, as in domestic animals. It serves to bring out the characters in pure form, and the desirable ones can be retained. The majority of the various breeds of cattle have been improved to their present degree by the aid of close inbreeding. In animals where inbreeding has not been practiced, the first result is often a marked deterioration of the stock, as in chickens.

In man close inbreeding has often been forbidden by custom or taboo, and a certain degree of crossbreeding (exogamy) required. Whether this has been based on an obscure recognition of the bad effects of inbreeding, or solely on totemistic or ritualistic grounds, is not clear. It is a fact that undesirable hereditary conditions tend to be commoner in the offspring of related parents.

Crosses between different human races often seem to produce hybrid vigor, just as in lower animals and plants, and the abilities of the an-

cient Greeks, the modern French, the English, the Germans, and the Americans have been attributed by some to their hybrid origins. Nevertheless, in some countries the mating of persons of visibly different races, in particular of different color, is frowned upon, and in some places it is against the law. It is true that the offspring of such matings may find themselves in a socially stigmatized group, and may suffer as a result, but there is no reason to think such matings are bad for the stock. The studies which have been made suggest the contrary. The offspring of mixed Indian-white unions in the United States were analyzed by Dixon, who found them to have a higher fecundity and vitality than the pure Indians. Half bloods are generally taller than either parent race, and thus show hybrid vigor. Studies of the crosses between Hottentots and white Boers in Africa showed the offspring to be taller than either parent race and to exhibit a high fecundity and vitality. The offspring of the English and Polynesians in Pitcairn's Island are physically a superb group.

Those who object to race crossing in man often allege that the offspring are inferior mentally, and it is often claimed that some races are less intelligent than certain others. There is no scientific evidence for this; some of the so-called intelligence tests formerly used which seemed to reveal such differences have been shown to depend upon some something which is learned in urban as opposed to isolated rural environments, not on inherent native intelligence. So far as we know at present, genes for mental ability are distributed more or less evenly among the various human races.

CROSS FOX, a color variety of the common American red fox (*Vulpes fulva*). Its parents may be ordinarily colored. The name is derived from a dark cross on the shoulders of the individual. The pelt of the cross fox is more highly prized than that of the normally colored red fox.

CROSS IN MYTHOLOGY. See NATURE WORSHIP; SWASTIKA.

CROSS KEYS, Virginia, formerly a post village in Rockingham County, 20 miles north-east of Staunton, where a battle took place June 8, 1862, between the Union and Confederate forces. The engagement was a strategic success for the Confederates.

CROSS KEYS, Battle of, an engagement of the American Civil War fought near Harrisonburg, Va., June 8, 1862. Gen. John C. Frémont, the Union commander, with 10,000 infantry, 2,000

cavalry and 44 guns, was pursuing "Stonewall" Jackson up the Shenandoah Valley. His leading brigade, commanded by the French Gen. G. P. Cluseret, contacted Gen. R. S. Ewell's division (6,000 infantry and 500 cavalry) at Cross Keys. Two Union brigades were committed to Cluseret's right, and two to his left. Ewell's counterattack on the Union left was successful and the entire line fell back to reorganize at 6 p.m. Frémont badly mismanaged his battle plan. Union losses in killed, wounded and missing were 684, while those of the Confederates were 288.

CROSS-VINE. See BIGNONIA.

CROSSBILL, krös'bil, a bird of the genus *Loxia*, belonging to the finch family (Fringillidae), and having an unusual bill, the mandibles of which are much curved and cross each other at the points when the bill is closed. This enables the bird to obtain the pine seeds, which are its chief food, by tearing apart the scales of the cone with a strong lateral movement of its mandibles and removing the seed with its tongue, which has a scooped bony tip. The birds are native to the Northern Hemisphere where they live mostly in the pine and spruce forests and go about in small, chattering flocks. They breed in the very early spring and build their nests of twigs, bark, and moss usually in the branches of conifers and well above the ground. The eggs are pale bluish-green with brownish and lavender spots near the larger end.

Two species of crossbill common to North America are the red crossbill (*L. curvirostra*) and the white-winged crossbill (*L. leucoptera*). The males of both species are red with black wings, the latter species having two white bars across the wings; the females are olive brown. According to an ancient legend, the bird in pity tried so hard to draw the nails holding the Saviour's hands and feet to the cross, that its bill became crossed and its plumage tinged with His blood.

CROSSBOWS (also called ARBALESTS) are bows mounted at right angles upon a tiller, or stock, with a top groove for the arrow and a cylindrical catch, called a nut for catching and holding the string and a trigger for releasing it—the whole arranged to be discharged from the shoulder as with a modern rifle. Early crossbows had wooden bows and were braced (the string drawn to the nut) by hand, a stirrup at the bow end receiving the foot while the hands drew the string. Later came composite bows (made of whalebone, or horn, wood, sinew, and glue) and eventually bows of steel.

Bracing.—The methods of bracing the stronger crossbows varied: by cord and pulley—the cord, one end attached to the belt the other to the bow stock, passed through the pulley a hook on which engaged the bowstring; by gaffie—a hook attached to the belt; by a goat's foot lever, or hind's-foot (*pie-de-biche*)—an articulated lever with hooks for the string at one end and two long prongs at the other to slide over lugs in the sides of the stock and act as a moving fulcrum when the lever was drawn backward; by a windlass, or block and tackle arrangement; by a cric (Fr.; Eng. crick), or *cranequin*—a crank with gears acting on a toothed rack with hooks for the string at one end and a cord loop at the other to slip over the stock.

Each of these devices was attached, used, and detached, every time the weapon was fired.

(A) Hungarian, with composite bow, 15th century; (B) French, with windlass in place, 16th century; (C) Chinese, self-loading, repeating crossbow and darts, 18th century; (D) "goat's-foot lever" in use to draw crossbow string, 16th century.

It was partly because of the length of time required to brace the crossbow that its use in warfare was limited. The longbowman could shoot six or more arrows to every bolt loosed by the crossbowman. Yet its greater range made it indispensable in the defense of fortifications while its silent discharge suited it admirably for hunting. Though the crossbow was generally superseded in open warfare by the handgun in the beginning of the 16th century, it was popular with sportsmen and foresters for more than a century longer.

In some of the heavier, more powerful steel crossbows, the pull on the bowstring when drawn to the nut was well over half a ton. The string was made of pure hemp or flax cord formed into a many-stranded skein with loops at both ends and had to be put in place with the aid of a bastard string which bent the bow far enough to allow the (shorter) bowstring to be slipped over its ends. Thus the string of a crossbow stayed in place once it was strung. Many of the early composite crossbows had bows without curvature (or with slight reverse curve) when unbraced—the bowstring hanging slack when not in use. Crossbow arrows are called bolts, or quarrels, are short and relatively heavy, and are feathered with wood, leather, or parchment vanes.

Types of Crossbows.—The *arbalète-à-jalet* (or *galet*) or prod (also prodd)—a small, lightweight, hand-spanned crossbow for shooting pellets or stones to stun or kill rooks, rabbits, and other small game, was introduced about 1500. It had a stock curved downward between bow and nut and a double bowstring with a small string pocket, or cradle, to hold the stone missile. A somewhat later and stronger weapon for the same purpose, also called a prod (or prodd) or pellet bow, had a built-in steel spanning lever and a stock of metal. Pellet bows were used well into the 18th century. The slurbow, introduced about the same time, had a wood or metal barrel attached to the stock. The barrel, doubtless suggested by the handgun, was slotted at the sides to allow the bowstring to move back and forth along the stock, and featherless bolts, not bullets, were the missiles used.

Crossbows, though generally thought of as medieval weapons, were in use in Roman times and also by the Chinese prior to the Han Dynasty. Some of the ballistas of ancient and medieval times were merely huge crossbows braced by handwheels working a worm-screw-nut mechanism. The Second Lateran Council in 1139 (and Pope Innocent III later), interdicted the use of crossbows, except against infidels, as barbarous "because of their frightfulness," a prohibition which had little effect. Richard I of England (r. 1189–1199) and Philip Augustus of France (r. 1179–1223) armed some of their crusaders with crossbows. The weapon was subsequently replaced in England by the longbow while its use continued on the continent. At the Battle of Crécy in 1346 the French were credited with having at least 6,000 Genoese arbalesters (crossbowmen), though the English won the day with the longbow.

Armor, Metropolitan Museum of Art, New
York.

CROSSES AND CRUCIFIXES. The cross in varying forms has been used almost universally as a symbol and ornament. It has represented variously the sun or the god of the sky, the four parts of the world, the four main winds that bring rain, the four elements—earth, air, fire, and water. The simple cross (+), widely and continuously depicted in both the Old World and the New World, dates from palaeolithic times, the oldest known being on pebbles found in Le Mas d'Azil in Southwestern France.

From the bronze age objects of many types bore a variety of cross forms, including that later named the Maltese cross (✠). A frequent and widespread type was the swastika (卐), also called Thor's hammer; the word is Sanskrit and the symbol nearly always served as a kind of talisman. Its origin is uncertain and its symbolism diverse, though frequently it represented the four points of the compass. Equally obscure is the history of the ankh (⚡), the Egyptian hieroglyph for life. The T shape (Greek letter tau) was used as a cross in the ancient Mediterranean world, being a common form for crucifixions. The Hebrew letter *thau*, having the T form in epigraphy and meaning sign or cross, had a sacred meaning for the Israelites, and in Ezekiel 9:4 is referred to as a sign made on the forehead.

In the apostolic age only St. Paul regarded the cross as sacred, but by the 2d century the cross was virtually the synonym for Christianity. The tau (*crux commissa* or *patibulata*, called the gibbet cross, or St. Anthony's cross) was the generally accepted form. Tertullian in the 3d century called the T the "true form of the cross," and mentioned it as the frequent gestural sign of the cross in daily and liturgical duties.

The simple or Greek cross (+), utilized for the Cross of St. George, may have been used as early as the 1st century, as on some Palestinian sarcophagi believed to be Christian. The Latin (†) cross (*crux immissa* or *capitata*) was found in a house, probably a cult place, in Herculaneum and must therefore date no later than 79 A.D. But representations before the 4th century are rare, so great was the fear of persecution, the abhorrence of idolatry, and the stigma of crucifixion.

Pagan symbols served as disguises—the tau, the swastika (*crux gammata* or, in Anglo-Saxon, *fyfot*, meaning many-footed), and the ankh (*crux ansata*) adopted by the Coptic Church of Egypt. The latter seems to have been almost exclusively Egyptian and when found elsewhere seems to have been inspired by Coptic custom. The tau, used in the Roman catacombs, might be hidden in a name, IRETNE, for example, or the actual letter T forming part of the name might be enlarged. A very common disguise in the 2d century was the anchor, itself a symbol of hope. Other objects were assimilated to the cross shape—trident, ship, orant (figure with arms outstretched in prayer), bird in flight, hatchet. The chrismon or so-called Constantin-

ian monogram (✠), used in pagan times as an abbreviation, was adopted by the Christians in part because it combined the Greek letters *chi* and *rho*, the beginning of the word *Christos*. It became a symbol of the Cross of Christ and was first used in epitaphs.

Constantine's vision of the Cross in 312, the official recognition of Christianity by the Edict of Milan in 313, and the traditional finding of the True Cross in Jerusalem by Helena in 326 stimulated public acceptance of the undisguised cross. From that time the Cross symbolized the triumph of Christianity. Constantine erected in the Roman Forum a statue of himself holding a cross-shaped lance. The Constantinian monogram was used on the *labarum* (military standard). The Cross appeared in the imperial diadem and scepter and in many shapes on imperial coinage.

Only late in the 4th century, however, did the triumphal cross receive monumental expression, as in the apse mosaic of Santa Pudenziana in Rome. This is a Latin cross, the type on which Christ is believed to have been crucified, and is covered with gems. Such jeweled crosses (*crux gemmata*) as well as foliated crosses were popular from the 5th century and at least that early a gemmed cross stood on Calvary.

The Latin cross was common everywhere until the Great Eastern Schism in 1054 when the Greek equivalent became more general in the East. Two other forms used in the 4th century, but known in pre-Christian times, were the monogrammatic cross (✠) and the *crux decussata* (X). The latter is called both St. Patrick's and St. Andrew's cross, the latter because it is the type on which, according to legend, St. Andrew was crucified. Used sporadically from the bronze age, it has been adopted as the national cross of Scotland.

Crucifixes.—The abolition of punishment by crucifixion in the 4th century lessened the repugnance to depicting Christ on the cross. The earliest records of a crucifix—a cross, generally of Latin type, bearing only the body of Christ—refer to its use in Syria, possibly in the 6th century. Monumental crucifixes probably originated in Syria where they were especially common among the Nestorians who upheld the humanness of Christ. The Monophysites of Syria and Egypt, who denied His mortal nature, used either the plain or decorated cross, like the richly jeweled Coptic crosses. By the 8th century there were certainly both sculptured and painted crucifixes in Syria. The latter continued in use in the East, and at Mount Athos a large painted crucifix is still raised in the middle of the iconostasis (the partition between the altar and the choir or nave of the church).

The crucifix, like the scene of the crucifixion, was rare in the West in the early Christian period and was probably introduced by Eastern monks and artists. Early crucifixes were usually flat with incised figures. There are references to painted wooden crucifixes of the Carolingian period, generally placed in the middle of the nave on a column, behind the altar or in front of the choir. After the Carolingian period they were largely replaced by sculptured crucifixes. The earliest extant examples date from the late 10th or early 11th century and are relatively small, like the Gero and Werden (Germany) crucifixes.

Monumental sculptured crucifixes were very

1. Processional cross. 2. Rood cross. 3. Gemmed and foliated cross, 8th century.

popular in the Romanesque period, with the change from the early Christian type of altar with baldachin to the medieval retable altar. They were encouraged by the full development of the liturgy of Good Friday with its adoration of the Cross. Monumental crucifixes were placed not only on altars but also on rood screens separating the nave (the church militant) from the chancel (the church triumphant).

In the 12th century the painted crucifix reappeared in Umbria and Tuscany and remained peculiar to Italy. Like many sculptured crucifixes it continued the Carolingian use of enlarge-

Sculptured cross at Monasterboice.

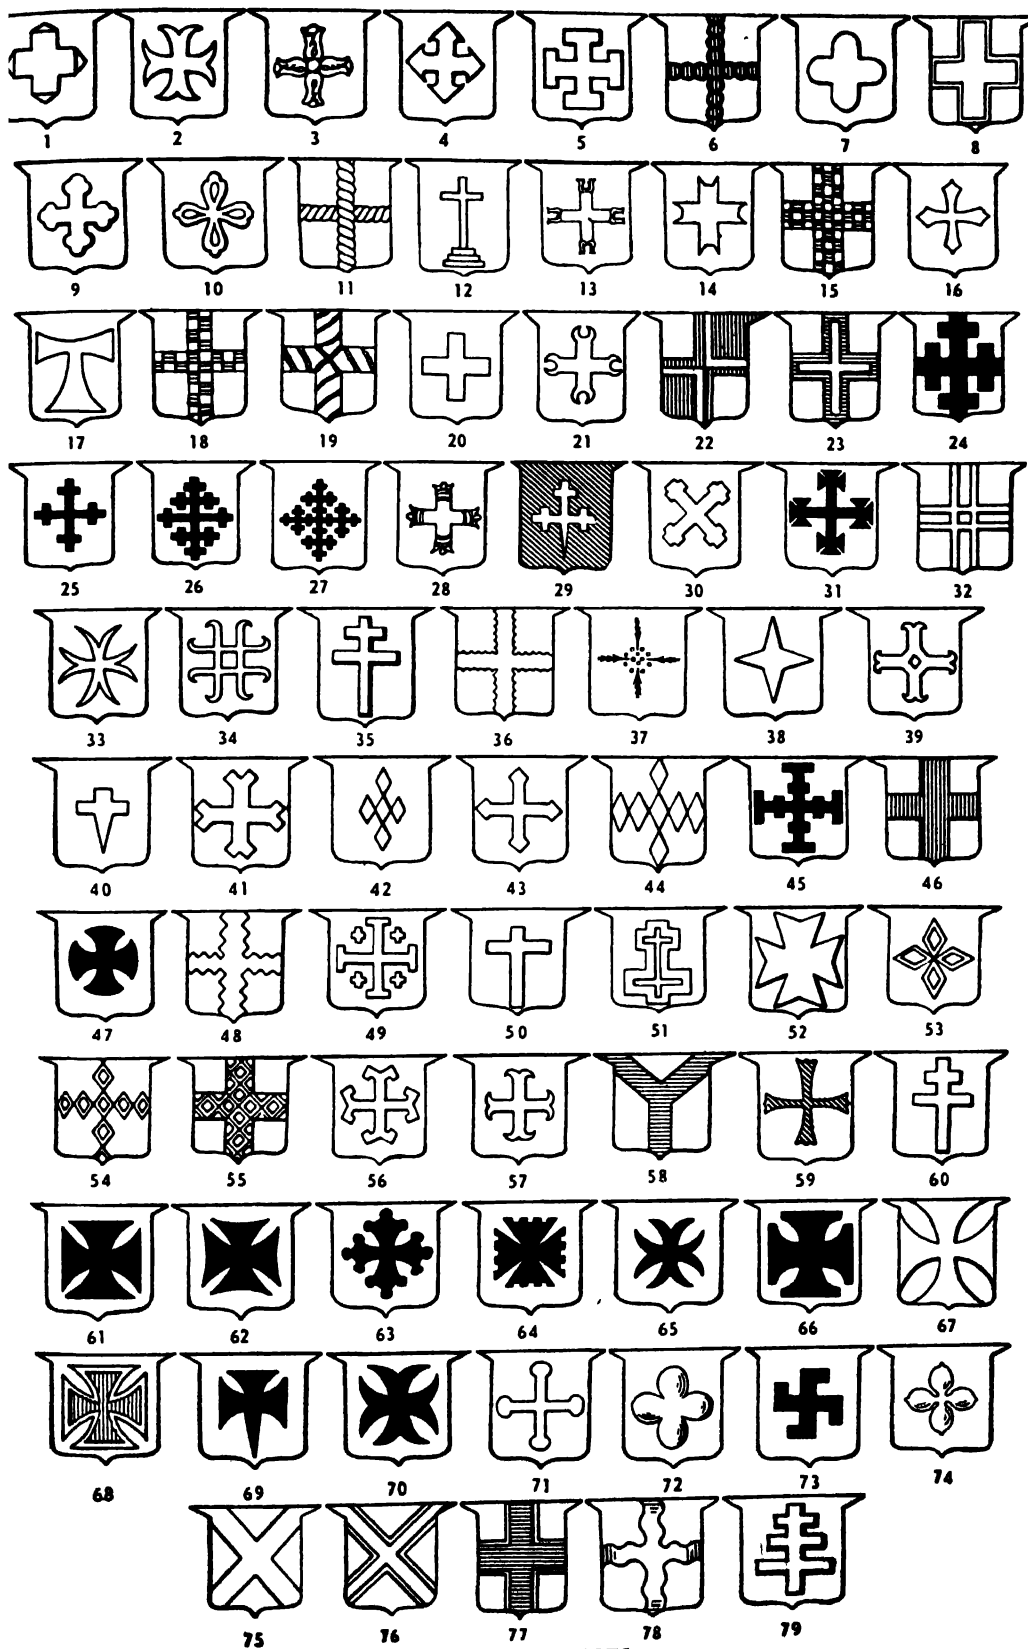

ments at the ends of the arms and upright. With secondary figures in the extensions and often scenes of the Passion around the body, these painted crucifixes pass from the realm of crosses into that of the Crucifixion.

The iconography of the crucified Saviour, whether fully clothed or wearing only the loincloth, whether alive or dead, usually paralleled the fashion in the larger Crucifixion scenes (See CRUCIFIXION.) Painted crucifixes of Italy showed Christ nude, both living and dead. By the 14th century, particularly in Germany, the suffering Christ was replacing the classic calm Romanesque type of Christ triumphant over death.

In the first centuries of the Christian era the cross was almost exclusively a sepulchral decoration. Later it was also adopted as the shape of freestanding memorials, monumental crosses like those of Bewcastle (England) and Ruthwell (Scotland) of the 7th century. Such crosses, often elaborately sculptured, were erected in Celtic countries possibly as early as the 5th century and were especially important in the British Isles throughout the medieval period. Cruciform shafts served as guides to travelers, as preaching crosses, as landmark or boundary stones. Roadside crosses, ranging from simple crosses and crucifixes to elaborate calvaries, abound in Europe and Quebec. Market crosses,

(75) Cross saltier (saltire) or cross of St. Andrew. (76) Cross saltier voided. (77) Cross fimbriated. (78) Cross undée or wavy. (79) Papal cross.

HERALDIC CROSSES
(See descriptions on preceding page)

reminding traders to practice Christian ethics, were a base for proclamations and originally for worship. The churchyard cross, perhaps at first a gathering place for prayer, received on Palm Sunday the pyx (box) containing the sacred Host.

Heraldic Crosses.—The cross is by no means limited to religious use; most variants are heraldic devices with no ecclesiastical significance. Cross forms are to be found on flags and ensigns and in wondrous variety in heraldry. The cross was one of the most common ordinaries (conventional figures), its use prompted primarily by the Crusades and pilgrimages to the Holy Land. Many forms served as insignia for military and civil orders, as the Cross of St. James and the Maltese cross, the emblem of the Knights

1. Latin cross. 2. Patriarchal cross. 3. Papal cross.

of St. John of Jerusalem. This cross has also an ecclesiastical meaning as an attribute of St. John the Baptist, the patron saint of the order, and symbolizes regeneration.

The cross has become the distinctive element in Christian religious decoration, as insignia for certain monastic orders, on ecclesiastical objects, in architectural details. Latin and Greek crosses have been the basis of many church plans, the former, for example, for Santa Croce in Gerusalemme in Rome, the latter for the Church of the Holy Apostles in Constantinople. The sign of the cross is an essential part of the liturgy, for benedictions, confirmations, consecrations, in the Holy Communion, and in ordination.

Certain cross forms have specific ecclesiastical uses or meaning. The patriarchal and papal

crosses, carried before the dignitaries concerned, are symbols of authority. Of early use, both were two-barred crosses but later, mainly for heraldic purposes, the papal cross was changed to three bars. A variant of either the Latin or the patriarchal cross, used by the Orthodox Church, is the Eastern (Russian) cross, which has a bar (*suppedaneum*, the footrest) slanting to the right near the foot. The Cross of Lorraine is a two-barred Latin cross, but with the second bar near the base. Its name derives from its adoption by Godfrey de Bouillon, duke of Lorraine, when he was declared by the Crusaders the first Christian king of Jerusalem. The Cross of Calvary or graded cross is a Latin cross mounted on three steps signifying faith, hope, and charity. A cross surmounting an orb, the Cross of Triumph, symbolizes the triumph of the Gospel throughout the world. The Celtic (Irish) cross, also called the Cross of Iona because an ancient example was found on that island, is a Latin cross with a circle, expressive of eternity, at the intersection of the arms.

Among ecclesiastical crosses is the pectoral cross (*encolpium*) which was in early Christian times an elaborate ornament, continuing the pre-Christian use of the cross as an amulet. From the 4th century it often was, like the altar cross, a reliquary containing pieces of the True Cross or relics of saints. It was not always a plain cross, but might be a crucifix or bear scenes from the life of Christ. Since the 17th century it has become a liturgical cross worn over the vestment by many clergy. The processional cross (*crux stationalis*) dates from the 4th century when it probably served also as the altar cross. It was used in processions to meet important functionaries and in litanies. In early Christian art Christ and St. Peter frequently carry such a cross of the Latin type. By the 13th century a plain cross was replaced by a crucifix and, being at the head of the procession, the whole symbolized the Christians as followers of Christ.

Legends.—Many traditions and legends have centered around the Cross of Christ. An early belief equated the Cross with the tree of life (Genesis 2:9) and pictorial representations, particularly in the Middle Ages, show the Cross with living foliage or as a tree. In an anonymous Anglo-Saxon poem entitled *Dream of the Rood* (*Vision of the Cross*) the Cross expresses its feelings at Christ's crucifixion. Several lines of this poem are inscribed on the Ruthwell cross. Another legend varying in length and complication—depending upon the narrator—traces the history of the Cross from the seeds of the tree of knowledge which, legend says, Seth planted over Adam's grave.

A 13th century version, in Jacobus de Voragine's *Golden Legend*, carries the story through Moses' legendary "planting" of the rods and the sprouting of Aaron's rod (Numbers 17:1-8), the eventual cutting down of the tree for Solomon's Temple, and its ultimate use as the Cross of Christ. This legend continues with the finding of the Cross by St. Helena, its capture by the Persians, and its subsequent recovery by Heraclius. Toward the end of the 14th century artists took up the theme. Noteworthy are the frescoes in the Church of San Francesco in Arezzo, Italy, painted by Piero della Francesca about 1452-1466 and depicting the story of the Cross as described in Jacobus' version of the legend.

Most feasts of the Cross originated in Jeru-

saalem to commemorate events relating to the True Cross. The Invention of the True Cross, celebrating its discovery, is observed by the Roman Catholic Church on May 3, and on September 14 by the Eastern Church. The Exaltation of the Cross (called Elevation in the East), originating in Rome, is held on September 14 and honors primarily the recovery of the Cross by the emperor Heraclius in 628. The East also celebrates on May 7 the appearance of the Cross in the 4th century to St. Cyril of Jerusalem, and on August 1 the translation of the relics from the palace in Constantinople (now Istanbul) to the Church of Hagia Sophia. The Armenian Church observes only one festival, the *Chatz*, in the autumn. The Adoration of the Cross is observed on Good Friday in both the Roman Catholic and the Eastern churches.

MARGARET A. ALEXANDER.

CROSSOPTERYGII, krō-sōp-tě-rīj'i-i (New Lat., fr. Gr. meaning fringe + fin), an order of bony fishes, the earliest of which are fossils of the Middle Devonian age, chiefly in Europe, North America, and Greenland. The most important fact regarding the group is that it includes the freshwater fishes which gave rise to the armored amphibia, Stegocephalia, in late Devonian time, and through them, to all succeeding tetrapod vertebrates. The crossopterygians, and also the closely related lungfishes or Dipnoi, are remarkable in having choanae or internal nostrils, and lungs for air breathing, in addition to gills. In view of these facts, Alfred S. Romer has proposed the name Choanichthyes (from Greek meaning funnel + fishes) for a subclass comprising these two orders. A common name for the crossopterygians is lobe-fin fishes, referring to the fact that their paired fins have the form of a projecting lobe, a sort of paddle-like limb containing bones and muscles.

There are two crossopterygian suborders. In one of them, the Rhipidistia (from Greek meaning fan + sail), which became extinct in the Lower Permian, several genera have paired fins in which the bones are strikingly comparable to the three long bones of the tetrapod fore and hind limb (respectively humerus, radius, ulna,

and femur, tibia, fibula); the tetrapod likeness also extends to many other anatomical features. Important Devonian genera are *Osteolepis*, *Eus-thenopteron* and *Sauripterus*.

The second suborder, the Coelacanthini (from Greek meaning hollow spines, referring to fin spines) migrated from fresh water to the sea, and persisted throughout the Mesozoic. They were believed to have become extinct by the end of that era, hence the capture of a five-foot living coelacanth off the South African coast in 1939 was a veritable zoological sensation. It was in general quite similar to certain Mesozoic coelacanths (*Undina* and *Macropoma*) but apparently is a new genus. It was named *Latimeria*. A second coelacanth, of another new genus, was caught by a fisherman near the island of Anjouan in the Comoro group, between Africa and Madagascar, in 1952. It was given the generic name *Malania*. These recent coelacanths are said to lack internal nostrils, possibly a secondary condition related to marine life. See also ICHTHYOLOGY.

CROSSWORD PUZZLES. The crossword puzzle is a direct descendant of the ancient word square in which the letters spelled the same words horizontally and vertically. The crossword, however, is built on a pattern of black and white squares, with different words interlocking across and down, and with numbered definitions given as clues to the words.

According to *Famous First Facts* (by Joseph Nathan Kane), the first crossword puzzle was put together by Arthur Winn and appeared in the supplement of the New York (Sunday) *World* of Dec. 21, 1913. It remained as a Sunday feature of modest popularity and underwent various improvements in form until the next important date in its history, April 10, 1924, when the first book of crossword puzzles appeared. It was edited by the three New York *World* puzzlers, Margaret Petherbridge (Farrar), Prosper Buranelli, and F. Gregory Hartswick, and was published on the first list of Simon & Schuster, Inc. This touched off what became in 1924-1925 first a nationwide and then a worldwide craze, and thereafter established itself as a permanent pastime in the word-game field.

Other newspapers began to print crossword puzzles, and the *World* pioneered in starting a daily series in 1924. The New York *Herald Tribune* soon followed suit. The New York *Times* has had a crossword page in its Sunday magazine since February 1942, and a daily series since September 1950. The crossword puzzle continues as a daily and/or Sunday feature in a high percentage of the world's newspapers.

The British took up the puzzles in 1925, first importing American books but soon developing a style of their own with many more black squares to the pattern and with abstruse definitions. A puzzle constructor who signed himself Torquemada gained a wide following, and in *Punch* a business executive is pictured as requesting his secretary to "look up 'herdic' in the

Oxford English; see if you can find an 11-letter alternative for 'courage' in the thesaurus; work out an anagram for 'orfruw' meaning a narrow trench; and then ring up the Natural History Museum and find out what two-word omnivorous mammal always produces quadruplets of identical sex."

Gradually crosswords were taken up all over the world, and are printed in all languages except those which, like Chinese, do not lend themselves to across-and-down manipulation. *Les Mots Croisés* prove that the French language is well adapted to the word game, and in Canada a bilingual type is popular, with French words reading one way and English words the other, carrying English and French definitions. In Russia the puzzles have been used for propaganda purposes, having specially slanted definitions.

In the United States the original series of puzzle books has been coming out at the rate of two or three a year and has sold over two million copies. In paper covers, many millions more have been sold, and a dozen or more crossword magazines are to be found on the newsstands.

A completed crossword puzzle.

Variations such as topical puzzles based on news words or words from some other category, puzzles for children, diagramless puzzles in which the diagram is reproduced from the numbered definitions, an American version of the British type having puns and anagrams, have become popular. By 1930 the term "crossword puzzle" rated a place in the dictionaries whose use it has so ably boosted.

The rules for crossword construction, as worked out in the United States, are: symmetrical pattern limited to one-sixth black squares; all over interlock, with no segments cut off from the rest; no unkeyed letters, that is, letters in one word only.

The quality of puzzle construction is gauged the low word total in proportion to the size the pattern, and of course by the ingenuity of the word combinations. Fewer and longer words make for more interesting solving. The quality of the definitions is also an important factor. Recent developments in construction allow for more than one word per space, so that full names, book titles, phrases, quotations and parts of them may appear. The crossword is

capable of constant variation; and in addition to pure entertainment, educational and therapeutic values have been claimed for it.

MARGARET FARRAR.

CROTALARIA, kröt-ä-lä'rī-ä, or **RAT-TLEBOX**, is a large genus of some 250 to 300 annual and perennial herbs and shrubs of warm regions, belonging to the pulse or pea family (Leguminosae). The leaves are simple, the flowers often yellow, and the loose seeds rattle in the coriaceous inflated pods (legumes) about two inches long, hence the name. Four species occur in the eastern United States, some like *C. spectabilis* having been introduced from the tropics. Rabbitbells (*C. angulata*) is a perennial found from Virginia to Florida, Louisiana, and tropical America. Some species are cultivated, especially in the South.

CROTALIDAE, krō-täl'i-dē, a family of venomous snakes comprised of the pit vipers. All members of this family have a conspicuous pit on each side of the face between the eye and nostril. These pits, the basis for the name pit viper, are extremely sensitive heat receptors; they enable these snakes to detect the presence of warm-blooded prey. The group is often classified as a subfamily (Crotalinae) of a more inclusive family (Viperidae) in which the true vipers also are placed. Representatives of the group in the Western Hemisphere include the rattlesnakes, water moccasin, copperhead, fer-de-lance, and bushmaster. Pit vipers also occur in Asia, one species ranging as far west as eastern Europe.

CROTHERS, krūth'ērz, **Rachel**, American playwright: b. Bloomington, Ill., Dec. 12, 1878. After graduating from Illinois State Normal School she entered the Wheatcroft School of Acting in New York, where she soon turned from student to instructor and coach. Her first success, *The Three of Us*, produced by John Golden in 1906, was followed by a long series of plays, nearly 30 during her active career, many of them given high critical praise. Outstanding are *A Man's World* (1909); *Once Upon a Time* (1918); *Nice People* (1921); *Let Us Be Gay* (1929); *As Husbands Go* (1931); *When Ladies Meet* (1932); *Susan and God* (1937), considered one of her finest.

In 1939 she received the Chi Omega National Achievement award. She is regarded by many as the leading woman dramatist of her time. Her plays—directed and supervised by herself—deal most often with moral and social questions affecting women, and have been notable for careful construction. She headed and actively participated in war relief work by stage women in both world wars.

CROTHERS, Samuel McChord, American clergyman and essayist: b. Oswego, Ill., June 7, 1857; d. Cambridge, Mass., Nov. 9, 1927. After attending Wittenberg College, Ohio, and the College of New Jersey (now Princeton), he graduated from Union Theological Seminary, New York, in 1877. For several years he was a Presbyterian minister, serving in Nevada and California and becoming known as "bishop of the Northwest." Then his growing liberal views led him to Unitarianism, and after attending Harvard Divinity School he was ordained a Unitar-

ian minister in 1882. He was called to Brattleboro, Vt., then to St. Paul, Minn., and finally to Cambridge, Mass. (1894), where as pastor of the historic First Parish he did his most enduring work. Crothers was one of the preachers to Harvard.

Though an able pulpit speaker, particularly forceful on personal liberty and the freedom of the soul, Crothers became generally known for his long series of familiar essays written in an easy, semiserious style charged with whimsical humor. *The Gentle Reader* (1903) won him a wide audience; others include *The Understanding Heart* (1903); *Among Friends* (1910); *Humanly Speaking* (1912); *The Dame School of Experience* (1919); *The Cheerful Giver* (1923); and appreciations of Charles Dickens, Oliver Wendell Holmes, and Ralph Waldo Emerson.

CROTON, krō't'n, is a genus of more than 600 species of frequently strong scented, hairy or glandular trees, shrubs, or rarely herbs, mostly found in the warm parts of the world, belonging to the spurge family (Euphorbiaceae). The Greek name *kroton* (tick) is based on the resemblance of the seeds to ticks. Several species are found in the southern and eastern United States such as hogwort or woolly croton (*C. capitatus*), prairie-tea (*C. monanthogynus*), and skunkweed (*C. texensis*). Hogwort and skunkweed are poisonous if eaten by cattle with hay. The poisonous principle may be the same as that found in other species of the genus. Economically important species are *C. cascarilla* and *C. eluteria* of the Bahamas which yield cascarilla bark used as a tonic, *C. tiglium* of India and Ceylon, source of croton oil, *C. lacciferus* which yields a lac resin for varnish-making.

Croton oil, obtained from the seeds of *C. tiglium*, is a yellow or brownish, slightly viscid, and somewhat fluorescent liquid with a faint, characteristic odor, containing oleic and other acids and a mixture of various substances. If applied externally, croton oil may cause blistering and irritation of the skin. Being the most drastic purgative, croton oil no longer has a place in modern medicine. In addition to oil, the seeds contain a toxic mixture of globulin and albumose, known as crotin, which attacks blood corpuscles and the central nervous system.

The crotons grown in gardens and greenhouses for their ornamental foliage belong for most part to *Codiaeum variegatum*, native in Malaya and the Pacific Islands like the five other species of this genus which is also a member of the same family.

CROTON AQUEDUCT AND CROTON DAM. See **AQUEDUCTS**.

CROTON OIL. See **CROTON**.

CROTON-ON-HUDSON, village, New York, in Westchester County, is situated near the mouth of the Croton River, on the east bank of the Hudson, 34 miles north of New York City, on the New York Central Railroad. It is a residential community, but has railroad maintenance shops and manufactures of handbags and perfume. The village was settled by the Dutch in 1609, incorporated in 1898, and in 1930 was enlarged by the addition of Harmon. Pop. (1950) 4,837.

CROTON RIVER, river in New York which rises in Dutchess County, runs south through Westchester County, emptying into the Hudson at Croton Point, 32 miles north of New York City. Its length is nearly 60 miles. Since 1842 the Croton watershed, covering an area of about 362 square miles above Croton Dam, has supplied New York City (that is, the present Borough of Manhattan) with water through Croton Aqueduct. Reservoirs along the course of the river include Boyd's Corners, Middle Branch, East Branch, Titicus, Carmel, Cross River, Bog Brook, Amawalk, New Croton, and Croton Falls.

CROTONE, krō-tō'nā (formerly Cotrone, kō-trō'nā; ancient CROTONA or CROTON), commune, Italy, in Catanzaro Province, Calabria, on the Gulf of Taranto. It has a good harbor and is a commercial and industrial center for a region producing grains, olive oil, dairy products, livestock, and sulphur. Its important chemical and metallurgical works are run by power obtained from a large hydroelectric plant in the Silagian Mountains (Ital. La Sila). The city is also a bishopric, with a cathedral, castle, and museum of antiquities.

The ancient town was founded by the Achaeans as a Greek colony about 710 B.C., and became famous for its athletes, among them the celebrated Milo (6th century B.C.), and as the city where Pythagoras taught between 540 and 530 B.C. Livy gives the circumference of the ancient city as 12 miles. In 510 B.C. Crotona defeated the neighboring Sybarites in battle and destroyed their city, but in 480 B.C. its own forces were defeated by the Locrians and Phlegians. It was later captured by Dionysius the Elder, of Syracuse, and in 299 B.C. was taken by Agathocles. In 277 B.C. it came under Roman rule, but after the battle of Cannae revolted from Rome and for three years was the winter headquarters of Hannibal. During the invasion of Italy in World War II the town was bombed by the Allies, and was taken by British troops in September 1943. Pop. (1951) 31,895.

CROTOPHAGA, krō-tōf'ā-gā, a genus of birds, the typical one of the subfamily Crotophaginae. The bill is greatly compressed and the ridge of the upper mandible keeled. The species are found in South America. *C. ani* is the ani, the razor-billed blackbird of Jamaica, also the savanna blackbird and the great blackbird. It feeds on small lizards, insects, and seeds. See also **ANI**.

CROTUS RUBIANUS, krō'tūs rōō-bī-ā'nūs (real name Johannes Jäger, yā'gēr), German humanist: b. Dornheim, Thuringia, about 1480; d. about 1539. He was educated at Erfurt, and from 1510 to 1515 was head of the monastery school at Fulda. In 1515 he contributed several satirical letters on scholasticism and monasticism to the first part of *Epistolae Obscurorum Virorum*. He was in Italy from 1517 to 1520, visiting Rome and Bologna, and in 1521 became rector of the University of Erfurt where he entertained Martin Luther. From 1524-1530 he lived at Königsberg as adviser to Duke Albert of Prussia. He had accepted the principles of the Reformation, but about 1530 reentered the Roman Catholic Church and became a canon at Halle. His *Apologia* was published at Leipzig in 1531.

CROUCH, Frederick Nicholls, English musician: b. London, Eng., July 31, 1808; d. Portland, Me., Aug. 18, 1896. He studied music with his father, an eminent violincellist, with his grandfather, a well-known organist, and at the Royal Academy of Music. He played in the orchestra of Drury Lane Theatre, sang in the choirs of Westminster Abbey and St. Paul's, and later (until 1832) played the violoncello in Queen Adelaide's private band. He composed numerous songs, including the famous *Kathleen Mavourneen* (published 1839-1840), the words of which were by a little-known Irish poet Mrs. Louisa Macartney Crawford (1790-1858). He also composed two operas, *Sir Roger de Coverley* and *The Fifth of November*. In 1849 he visited New York and remained as violincellist in the orchestra of the Astor Place Opera House. He taught music in Portland, Me., 1850-1856, and subsequently in Washington, D.C., and Richmond, Va. During the Civil War he served as trumpeter with the Confederate Army, and after the war settled in Baltimore as a teacher of singing. He is said to have invented the zincography process of printing music.

CROUP, krōōp, catarrhal laryngitis, is a condition of the larynx seen in children. This is a recurring laryngitis characterized by hoarseness, a harsh metallic or "brassy" cough and, if there is much difficulty in respiration, by a crowing sound on inspiration. Croup was formerly associated with diphtheritic membranous laryngitis and this type was referred to as diphtheritic croup. It is no longer so denoted. Croup is seen oftenest during the winter months and usually comes on at night. The cause is a coryza especially among those who have enlarged tonsils or adenoid growths. Intestinal disturbance is commonly regarded as a contributing factor. An attack of croup comes on suddenly, usually with some premonitory hoarse breathing, and the initial attack is frequently repeated on succeeding nights. The symptoms resemble those of strangulation and cause great anxiety to the parents of the affected child, although ordinary uncomplicated croup seldom or never results fatally.

The treatment advised is immediate immersion in a warm bath, the use of benzoin inhalations, and the administration of a mild opiate such as paregoric. Wine of ipecac is also recommended since prompt emesis will clear out mucus in the air passages. After relief is obtained a laxative is generally given. A period of several days of bed rest is advisable and protection against chilling is essential. If adenoids are present, their removal is indicated. The so-called "croup kettle," a small boiler with an inhalation tube attached, is useful in recurring croup. Water and medicaments are placed in the kettle and the steam is inhaled or allowed to humidify air surrounding the patient.

A type of croup is sometimes seen in which there is extreme spasm of the larynx. This is known as spasmodic laryngitis or *laryngismus stridulus*. The disorder is observed generally in children under the age of 18 months. Closure of the glottis during the paroxysm results in severe dyspnea. Spasmodic laryngitis is probably a nervous affection and has been reported related to tetany (q.v.). Respiration may cease for a considerable period, the face becoming congested to an alarming degree. After what seems a dangerous interval the spasm relaxes and air rushes

into the lungs accompanied by a high-pitched sound. In very young infants convulsions may be present. In every case of croup, whatever the cause, it is well to keep the child in a room with an even temperature, neither excessively warm nor unduly cold.

Croup due to influenza may be extremely serious. This type is often a fulminating infection due to *Hemophilus influenzae*. It is attended by high fever and acute laryngitis with respiratory obstruction. A few hours after the attack the child appears acutely ill, with labored breathing and deep cyanosis. Without specific therapy the outlook for recovery is poor and in a large proportion of cases death will occur in from 2 to 4 days. Where specific therapy is begun early with administration of sulfonamides, streptomycin, or occasionally, specific rabbit serum the prospect for recovery is said to be good.

The differential diagnosis between simple croup, laryngeal infection by the streptococcus, and laryngeal diphtheria is most important. Croup comes on at night, shows improvement in the morning and is generally without fever. Moreover examination of throat reveals no membrane formation. In other types, due to the streptococcus or *Hemophilus*, there is high fever, redness, and swelling of the fauces and air passages and a rise in blood leucocyte count. In laryngeal diphtheria the temperature is generally not over 102°F., hoarseness is prominent and increases, a membrane develops in the larynx, there is great respiratory embarrassment, and the pulse is rapid and often feeble. In every case of severe involvement of the larynx throat cultures should be made without delay in order to reveal the specific organism present and to initiate specific therapy if this is indicated.

HAROLD W. JONES, M.D.

CROUSE, krouse, Russel, American writer: b. Findlay, Ohio, Feb. 20, 1893. After attending common school and high school he began newspaper work in 1910, first as a reporter for the Cincinnati *Commercial-Tribune*, then with the Kansas City (Mo.) *Star*, the Cincinnati *Post*, and —following service in the navy in World War I— with the New York *Globe*, the *Evening Mail*, and the *Evening Post* (as columnist, 1925-1931). His books include *Mr. Currier and Mr. Ives* (1930), *It Seems Like Yesterday* (1931), *Murder Won't Out* and *The American Keepsake* (1932). With Howard Lindsay he was coauthor (1939) of the dramatization of Clarence Day's book *Life With Father*, of the 1946 Pulitzer Drama Award play *State of the Union*, and of *Life With Mother* (1948), the musical success *Call Me Madam* (1950, music by Irving Berlin), and *The Prescott Proposals* (1953).

CROUTER, Albert Louis Edgerton, American educator: b. Belleville, Ontario, Canada, Sept. 15, 1846; d. Philadelphia, Pa., June 26, 1925. He was educated at public and private schools in Belleville and later at Franklin Institute and the University of Pennsylvania. Moving to Kansas at the age of 20, he taught briefly in an Indian school at Shawneetown. There he met Thomas Burnside, superintendent of the Kansas School for the Deaf at Olathe, and became a teacher in that institution. Education of the deaf became his life work. He was especially interested in the oral method of instruction. In 1884 he became principal of the Pennsylvania Institution for the

Deaf at Philadelphia, and in 1892 supervised its removal to Mount Airy where during the 58 years of his administration it gained a world-wide reputation. One of the founders of the American Association to Promote the Teaching of Speech to the Deaf, he succeeded Alexander Graham Bell as its president in 1904, and in 1907 represented the United States at the International Conference of Instructors of the Deaf held at Edinburgh, Scotland.

CROW, krō, a name applied to many of the approximately 25 species of the genus *Corvus*, a group of which a typical member is the raven and which includes also the rook (qq.v.). The term "crow family" is sometimes used for the entire family Corvidae which contains, in addition to the genus *Corvus*, the jays, magpies, nutcrackers, and a few others. Though technically songbirds, crows do not have a musical song; their discordant cawing is well known. Crows average about a foot and a half long and have a wingspread of from two to four and one-half feet, the raven being the largest and the most powerful of all perching birds. Most crows are entirely black, but a few Old World ones, such as the hooded crow, have some white in the plumage.

Crows are strong-legged, robust birds of omnivorous feeding habits. The bulk of their diet consists of seeds and harmful insects but they supplement this with the eggs and young of other birds. In the winter, especially, they visit the shore to search for dead fish or other edible matter. Offal is also taken, particularly by the carrion crow (*C. corone*) of Europe. At times, crows are destructive to corn, which they often remove from the ground as soon as it is planted. Although they are shot and poisoned at every opportunity by many farmers and sportsmen, crows, wary and cunning by nature, survive in large numbers. Many authorities consider crows and ravens to be the most highly evolved and intelligent of all birds.

The American crow (*C. brachyrhynchos*) is found over most of the United States and southern Canada. Each pair builds a strong nest of twigs, lined with grass and strips of soft bark and situated in a fork of a tree, some 10 to 40 feet above the ground. The three to six eggs are bluish green, heavily marked with brown. Young crows make amusing pets and can sometimes be taught to imitate a few words of human speech. The belief that splitting the tongue improves this speaking ability is entirely fallacious. In winter the American crow assembles at night in huge roosts containing thousands of birds. By day the crows scatter far and wide to search for food. Only in very cold regions such as the plains of western Canada does this crow migrate south in winter. The fish crow (*C. ossifragus*) of North America is a closely similar but somewhat smaller species which frequents the eastern seaboard and to a certain extent inland river valleys.

CROWBERRY (*Empetrum*), the largest of three genera belonging to the small crowberry family (Empetraceae), includes several species of low, shrubby, heathlike evergreens with small, narrow, stiff, and revolute leaves, apetalous flowers, and berry-like, edible fruits (drupes). The black crowberry (*E. nigrum*) occurs from the Arctic zone to New England, New York, Minnesota, and northern California as well as in Eurasia, and has a dark-fruited and a white-fruited

form. The purple crowberry (*E. atropurpureum*) with red or purple-black fruits is found from Labrador to New England. Its counterpart, *E. rubrum*, occurs in Patagonia, southern Chile, and some antarctic islands. The third species found in eastern North America is the rockberry, *E. Eamesii*, with pink or light red fruits. Members of this family are difficult to cultivate and have little economic value.

CROWDER, krou'dēr, **Enoch Herbert**, American soldier: b. Edinburg, Mo., April 11, 1859; d. Washington, D.C., May 7, 1932. Graduating from the United States Military Academy at West Point in 1881, he was commissioned a 2d lieutenant in the 8th Cavalry at Fort Brown, Texas, studied law, and in 1884 was licensed as an attorney in Hidalgo County, Texas. The following year he was detailed to the University of Missouri at Columbia as professor of military science and tactics and did much to advance military training for students. While there, he took a course in law and received the degree LL.B. in 1886. In 1891 he was assigned as captain and acting judge advocate to the Department of the Platte at Omaha, Neb., and in 1895 was made a major in the Department of the Judge Advocate General in which he served until he retired from the army in 1923.

During the Spanish-American War, Major Crowder served as judge advocate in the Philippines; in 1903 was promoted colonel and appointed chief of the 1st Division of the first General Staff of the army. In 1904-1905, during the Russo-Japanese War, he served as American military observer with the Japanese Army in Manchuria. He was in Cuba from 1906 to 1909 as a member of the provisional governor's staff and headed the commission for drafting the basic laws of the republic. In February 1911 he was made judge advocate general of the army with the rank of brigadier general. Early in 1917, at the request of the secretary of war, he drafted the selective service bill which Congress enacted into law on May 18. After serving as United States ambassador to Cuba, 1923-1927, he retired from public service and opened law offices in Chicago, practicing until ill health compelled his retirement in 1931. His grave is in Arlington National Cemetery.

CROWE, Catherine (nee STEVENS), English novelist: b. Borough Green, Kent, England, about 1800; d. ? Edinburgh, Scotland, 1876. She was deeply interested in spiritualism and is best known for her *Night Side of Nature* (1848), considered one of the best collections of supernatural stories in English. She abridged *Uncle Tom's Cabin* for juvenile readers; wrote several novels, the most successful being *Susan Hopley* (1841) and *Story of Lilly Dawson* (1847); and was the author of the treatise *Spiritualism and the Age We Live In* (1859).

CROWE, Eyre Evans, English journalist and historian: b. Redbridge, Southampton, England, March 20, 1799; d. London, Feb. 25, 1868. He attended Trinity College, Dublin, Ireland, but left before graduating to enter journalism in London. He published several novels and historical works, including a 5-volume *History of France* (1858-1868), and was editor of the *Daily News*, 1849-1851.

His elder son, EYRE CROWE (b. London, Oct. 3,

1824; d. there, Dec. 12, 1910), studied painting with Paul Delaroche in Paris, was elected an associate of the Royal Academy in 1876 and full member in 1888. Two of the best known of his many paintings are *Brick Court, Middle Temple* (1863), and *The Queen of the May* (1879). In 1852-1853 he visited the United States with William Makepeace Thackeray, acting as his secretary, and later published *With Thackeray in America* (1893), and *Haunts and Homes of Thackeray* (1897).

SIR JOSEPH ARCHER CROWE (b. London, Oct. 20, 1825; d. Baden, Germany, Sept. 6, 1896), younger son of Eyre Evans Crowe, was a special war correspondent in the Crimea and in India, and director of the art school at Bombay in 1857-1859. From 1860 to 1882 he held various European posts in the British diplomatic service, wrote extensively on art subjects, and collaborated with the Italian critic Giovanni Battista Cavalcaselle on *Early Flemish Painters* (1857) and the noteworthy 5-volume *History of Painting in Italy* (1864-1871). He published his *Reminiscences* in 1895.

His son, EYRE ALEXANDER BARBY WICHART CROWE (b. Leipzig, Germany, July 30, 1864; d. Swanage, England, April 28, 1925), was educated at Düsseldorf, Berlin, and Paris, and entered the British Foreign Office in 1885, becoming counsellor of embassy in 1907 and assistant under-secretary of state in 1912. Prior to World War I he devised the plan for seizing German shipping in British ports which was put into operation when war broke out, and was minister plenipotentiary at the Paris Peace Conference. In 1920 he became permanent under-secretary for foreign affairs.

CROWE, William, English clergyman and poet: b. Midgham, Berkshire, England, where he was baptized Oct. 13, 1745; d. Bath, Feb. 9, 1829. He was educated at Winchester College and at New College, Oxford. Though he published sermons, orations, and other works, he was best known for his poem *Lewesdon Hill* (1788), which was highly regarded by William Wordsworth and other poets of his day. He was the author of *A Treatise on English Versification* (1827).

CROWELL, krō'el, Edward Payson, American educator: b. Essex, Mass., Sept. 7, 1830; d. Amherst, Mass., 1911. Educated at Amherst College and at Andover Theological Seminary, he was successively instructor in German at Amherst, professor of Latin language and literature, and, 1880-1894, dean. He edited many of the Latin classics and was author of *A Clue to the Prose Writings of the Silver Age* (1897), among other works.

CROWELL, Grace (nee NOLL), American poet: b. Inland, Iowa, Oct. 31, 1877. She was educated at German English College, Wilton, Iowa, and in 1901 married Norman H. Crowell of Dallas, Texas. A writer of verse since 1906 and winner of numerous poetry prizes, she was poet laureate of Texas, 1935-1937, and in 1938 was named by American publishers as one of the 10 outstanding women of the year. Her most recent works include *Apples of Gold* and *A Child Kneels to Pray* (1950); *Meditations* (1951); *Brightest Harvest* and *Little Boy Down the Lane* (1952); *Moments of Devotion* (1953).

CROWELL, John Franklin, American economist: b. York, Pa., Nov. 1, 1857; d. East Orange, N. J., Aug. 6, 1931. He was educated at Yale and Columbia universities, and studied also at the University of Berlin, Germany. After several years of college teaching, he became associated with the United States Treasury Department as an expert of the Industrial Commission, and also as an expert on internal commerce for the Bureau of Statistics. He was an editorial writer for the *Wall Street Journal*, 1906-1915; president of the American Civic Alliance, 1910-1911; executive officer of the New York State Chamber of Commerce, 1915-1917; and director of the World Market Institute, New York City, 1919-1921. Crowell published numerous works on economics and related subjects, among them: *Taxation in the American Colonies* (1893); *The Logical Process of Social Development* (1898); *Internal Commerce of the United States* (1902); *Trusts and Competition* (1915); *Social Insurance with Special Reference to Compulsory Health Insurance* (1917); and *Government War Contracts* (1920). He also wrote on individual aspects of the United States economy, including farm products, iron and steel trade, lumber trade, and shipbuilding.

CROWELL, Luther Childs, American inventor: b. West Dennis, Mass., Sept. 7, 1840; d. there, Sept. 16, 1903. After attending an academy and also studying medicine for a year he served four years in the merchant marine, then went to Boston to develop an aerial machine which he had invented and for which he obtained a patent on June 3, 1862. Financial difficulties put a stop to this project, but while working on it he invented a machine for making paper bags which he patented in 1867. Five years later he invented and patented the square-bottomed paper bag and the machine for making it, and soon afterward the side-seam paper bag.

Crowell sold partial rights in his bag patents to a rival company, which he had sued for infringement of patent, and turned his attention to devising improvements in printing machinery. In 1873 he patented a rotary sheet-delivery and folding machine which was first used two years later in the new presses of the *Boston Herald*. R. Hoe & Company invited him to join them and he entered their employ in 1879, transferring his residence to New York City, and remained with them until his death. His inventions contributed substantially to advancements in printing, and he received more than 280 United States patents on printing machinery alone. He was a member of the American Society of Mechanical Engineers and of Franklin Institute.

CROWFIELD, Christopher, a pseudonym sometimes used by Harriet Beecher Stowe.

CROWFOOT. See BUTTERCUP.

CROWLAND or **CROYLAND**, town, England, in Lincolnshire, 8 miles northeast of Peterborough, on the Welland River. Its four principal streets intersect at a 14th century triangular bridge spanning streams now covered. On it is an early stone effigy, possibly that of the Saviour, which once crowned the west façade of ancient Crowland Abbey. The only edifice of note is the ruined abbey, which may have been built as early as 716

and rebuilt about 1100, the north aisle of which forms the parish church. Ingulf (d. 1109), to whom a history of the abbey of Crowland, first published at London in 1596, afterward at Oxford in 1684, has erroneously been attributed, was abbot of Crowland from 1075 until his death. Pop. (1951) 2,809.

CROWLEY, krō'li, **Robert**, English printer and social reformer: b. Gloucestershire 1518?; d. London, June 18, 1588. He received his B.A. from Magdalen College, Oxford, in 1542 and proceeded to set up his printing office at Ely Rents, Holborn. Although he printed many of his own works (some of them, such as *Way To Wealth*, 1550, and *Pleasure and Pain*, 1551, attacking the hierarchy of the richer classes), he is best remembered for his three impressions of William Langland's *Vision of Piers Plowman* (1550) and for his printing of Welsh books, many of them for the first time. One of his most notable original works was the continuation of Thomas Languat and Thomas Cooper's *Epitome of Chronicles* (1559).

As a deacon and minister, he manifested strong puritan tendencies, living in exile during Queen Mary's reign and being imprisoned in 1566 during Queen Elizabeth's reign because he refused to use any of "the conjuring garments of popery" during his ministry. He was, however, released and continued as a minister and a printer.

CROWLEY, krou'li, city, Louisiana, capital of Acadia Parish, altitude 29 feet, on the Southern Pacific and Missouri Pacific railroads, 98 miles south of Baton Rouge. It is the center of a rice district, and nearby are oil and natural gas wells. Rice-milling is the principal industry, and burlap bags, concrete blocks, and machine-shop products are also manufactured. A rice-growing experiment station here is under state and federal control. In November an annual National Rice Festival is held.

First known as Houstch, it was settled by Acadians in 1866 and was incorporated in 1889. It is governed by a mayor and council. Pop. (1950) 12,784.

CROWN, kroun, an official or symbolical ornament worn on the head, now the symbol of royalty. At first it had no regal significance and was nothing more than a garland of leaves or flowers bestowed on athletes. Later it was made of gold and bestowed on citizens deserving well of their country. In the Middle Ages the crown became exclusively appropriated to the royal and imperial dignity. For further information on regal crowns see **CROWNS** and **CORONETS**.

The term crown is also used figuratively for the royal power, in contradistinction either to the person of the monarch or to the body of the nation, with its representatives, interests, and powers.

In architecture, crown denotes the uppermost member of a cornice, usually called the corona (q.v.). It is also a sort of ornamental structure surmounting a tower and formed by flying buttresses meeting together at top.

In numismatics, the crown is an English coin worth five shillings, or about \$70. It was first minted in gold in 1526 in imitation of the French "Crown of the Sun," but was eventually struck mostly in silver to give England the equivalent of the German taler. The minting of crowns was

stopped from 1902 until 1927 and then continued until 1937 when it again stopped. Silver crowns were struck for the Festival of Britain (1951) and a small amount have been minted each succeeding year.

CROWN COLONIES. The name commonly given to the British dependencies whose government is controlled by the crown (in reality, the home government). A special department of the Colonial Office in London deals with the administrative and political work of the crown colonies and protectorates. The government of most of the colonies is administered mainly by natives and the crown or home government maintains a minimum of control. Typical crown colonies are those of Gibraltar and Cyprus.

CROWN GALL, a disease of many fruit and forest trees usually caused by *Phytophthora tumifaciens*, which obtains entrance usually at the juncture of the roots and the trunk (the crown), but sometimes appears upon the roots. In young trees the galls are often half an inch in diameter, colored like the roots or darker, soft and composed of apparently unorganized tissue, but in old trees they frequently show concentric rings and may become several inches in diameter. In Europe, America, and New Zealand, where this disease is known, considerable damage has been reported, even whole orchards being destroyed by the fungus. The only remedy thought to be of service is the annual removal of the galls and the covering of the wounds with thickened Bordeaux mixture.

CROWN GLASS, a very hard and clear glass, made almost entirely of sand and alkali and a little lime, without lead or any metallic oxide except a very small quantity of manganese, and sometimes of cobalt. The original balloon is flattened, crown-shaped. A steel rod tipped with molten glass is now attached opposite to the blow-pipe which in turn is removed. By rapidly revolving the rod on a horizontal axis opposite the large opening of the glass furnace, the mass of glass softens and spreads out into a disc, thick at the center and thinning toward the edges. The limit of the diameter of these discs is 50 inches. Crown glass is used in connection with flint glass for optical instruments, in order to destroy the disagreeable effect of the aberration of colors. This important discovery by John Dollond, who turned it to admirable account in the achromatic telescope, was carried to the highest perfection by Baron Karl von Reichenbach. This glass is much used for windows, especially for art work, where its peculiarly brilliant surface makes it most acceptable. See also **GLASS**, **VARIETIES OF**.

CROWN LANDS, territories in the British Isles formerly the private property of the sovereign. Since George III, however, every British monarch has on accession surrendered the crown lands to be disposed of by Parliament. The administration of these lands is in the hands of the commissioner of crown lands, and the income from them, like the other revenues of the state, is now devoted to the public service. The produce in 1950 amounted to £2,338,968 of which sum £655,610 was paid into the Exchequer. Before the Norman conquest (1066) all the so-called folk land gradually became *terra regis* or king's land. The confiscations of Wil-

liam the Conqueror greatly increased these terrains, but their redistribution among the king's followers so reduced them again that an Act of Resumption was passed under Henry III, and during the reign of Edward II an act was in force prohibiting the alienation of crown lands. The Wars of the Roses and the confiscations of Henry VIII enlarged the possessions by forfeiture and seizure, but the necessities of James I and Charles I compelled the disposal of the whole estates. These were partially recovered at the Restoration by the sales being declared void. An important constitutional effect was produced by the wholesale granting away of the crown lands; being thus deprived of a private income, the monarch had perforce to apply to Parliament and the nation for his income, which was not infrequently granted only on condition of good government. The extravagance of William III led to an act being passed in the reign of Queen Anne (1702-1714) by which further alienation was greatly checked, but in 1800 the act was declared not to apply to the private property of the sovereign acquired by purchase or inheritance from any person other than a sovereign of England. In 1910 the civil list of the king was fixed (after the usual surrender of hereditary revenues, i.e., the crown lands) at \$2,350,000.

CROWN POINT, city, Indiana, Lake County seat; altitude 709 feet; on the Erie and the Pennsylvania railroads; 36 miles southeast of Chicago. The surrounding area is predominantly agricultural; the city's principal industry is the making of agricultural implements. Crown Point has a public library. Settlement was made in 1834; a monument honors the founder, Solon Robinson, writer and editor. Government is administered by mayor and council. Pop. (1930) 4,046; (1940) 4,643; (1950) 6,500.

CROWN POINT, town, N. Y., located in Essex County; altitude 126 feet; on the west shore of the southern end of Lake Champlain; 109 miles north of Albany; served by the Delaware and Hudson Railroad; now primarily a summer resort with boating, bathing, and fishing facilities, is noted for its scenic beauty and for its history. During the later part of the 19th century it was the center of an extensive iron mining region. In the Crown Point Reservation, 113 acres in the Adirondack Forest Preserve, on N. Y. State Highway 8, is the Champlain Memorial Building built in 1909 by New York and Vermont to honor the memory of Samuel de Champlain (q.v.) discoverer of Lake Champlain, containing a Rodin bas relief of *La France* which was presented to the United States by the people of France in 1912. Here is Lake Champlain Bridge, also built by the two states; and the remains of Fort St. Frédéric, built in 1731 by the French who planned to make it the capital of the projected southern territory, and Fort Crown Point (formerly Fort Amherst). Here, in 1609, Champlain fought and defeated the Iroquois. Later, in 1714, Crown Point became an important English trading station named *Pointe à la Chevelure* (Scalping Point) by the French. In 1755, in the final phase of the contest between the French and the British in America, Sir William Johnson (q.v.) commanded an expedition against Forts St. Frédéric and Crown Point. This got no farther than Fort Edward and ended in

the bloody drawn Battle of Lake George (q.v.). In 1756 the French built Fort Ticonderoga, farther up the lake on the isthmus between Lake Champlain and Lake George. This made Crown Point a second instead of a first line of defense, but the two forts remained the chief French frontier posts throughout the war. In 1757 the forts were attacked by Maj. Robert Rogers' rangers (q.v.) and numerous raiding parties. General James Abercrombie (q.v.), led a British army against the forts, but he was repulsed with heavy losses at the Battle of Ticonderoga July 8, 1758 and forced to retreat. He was superseded by Jeffrey Amherst (q.v.) who, in 1759, while Gen. James Wolfe was taking Quebec, compelled the French to abandon Ticonderoga, and captured Crown Point. Both forts were kept up by the British and at the outbreak of the Revolutionary War were a part of the objective of the Colonial forces to open the route to Canada. In May, 1775, while Ethan Allen took Ticonderoga, Seth Warner (q.v.), captured Crown Point with 113 cannon and a quantity of ammunition. The British held it again in the move toward Saratoga in 1777, but thereafter the fort was no longer of any consequence. Pop. (1940) 1661; (1950 est.) 2,500.

CROWNINSHIELD, Arent Schuyler, American naval officer; b. Seneca Falls, N. Y., March 14, 1843; d. Mt. Desert, Me., May 27, 1908. He was graduated at the United States Naval Academy in 1863, and participated in both attacks on Fort Fisher in the Civil War. Later he rose to the rank of captain. During the war with Spain he was a member of the Board of Strategy. In 1900 he was chief of the Bureau of Navigation, with the rank of rear admiral; commander of the European squadron 1902-1903; a member of the Board of Naval Strategy; retired March 20, 1903.

CROWNINSHIELD, Frederic, American artist; b. Boston, Mass., Nov. 27, 1845; d. Capri, Sept. 13, 1918. Graduated at Harvard 1866; spent 11 years in Europe studying art under Thomas C. Rowbotham, Thomas Couture and Alexandre Cabanel, his first exhibited work appearing in the Paris Salon of 1878. He was instructor in the Boston Museum of Fine Arts 1879-1885, after which he removed to New York, where he was president of the Fine Arts Federation from 1900 to 1909. From 1909 to 1911 he was director of the American Academy in Rome. He was a member of the National Society of Mural Painters. He devoted himself largely to mural painting and stained glass work. His water colors are greatly admired and sought for by collectors. He published *Mural Painting* (1887); *Pictoris Carmina, a Painter's Songs* illustrated by himself (1900); *A Painter's Moods* (1903); *Tales in Metre* (1903); *Under the Laurel* (1907); *Villa Mirafiore* (1912).

CROWNS AND CORONETS, two of the types of headdress which symbolize the rank or honor belonging to the wearer. Crowns are generally worn only by rulers, coronets are worn by persons of lesser rank such as the nobility. Throughout history diadems, tiaras, fillets, wreaths, even hats and bonnets have had similar significance. The "open crown" is a headband with decorative projections on the upper rim. "Closed crowns" have arched segments over the

top of the head. A single band arched from the front to the back of the crown appears on the crown of Charlemagne, and a single band arching across the head from side to side is on the crown of the prince of Wales. The most frequent type is that with two bands of metal intersecting in the center beneath an orb, which is a sphere surmounted by a cross, the combination symbolizing Christian sovereignty. The velvet cap lining many crowns does not make them closed crowns.

Pre-Christian Era.—Although the 21st Psalm says "thou testest a crown of pure gold on his head," not all crowns were of metal. The material used for the crowns of ancient Egypt is unknown. The open, Red crown of the lower Nile and the closed, White crown of the upper (southern and upstream) Nile were combined into a single crown about 3200 B.C. when the two kingdoms were united. (Fig. 1).

A bronze coronet which in significance if not in form can properly be called a crown has survived from the Bronze Age, about 1000 B.C. Found in the Hohenzollern Province in the Black Forest region of Germany, and now in the Metropolitan Museum of Art, it is one of the oldest crowns in existence (Fig. 2).

In the Mycenaean and Greek civilizations the gods and goddesses were represented wearing low, open crowns. The Greeks bestowed wreaths of leaves or garlands of flowers on those they wished to honor. The makers and sellers of garlands formed a distinct trade. Wreaths were worn by dinner guests (to ward off drunkenness), by the bride and bridegroom, and, at funerals, by the corpse. The winner at the Olympic games received a wreath of wild olive. Crowns of leaves, whether for military, naval or civil honors were governed by law. When Athens substituted crowns of gold leaves for the olive garland the city bestowed them more freely than before, showing that while the cost increased the symbolic value decreased. The provinces gave golden crowns to victorious generals and many were bestowed on Alexander after he defeated Darius. The tiara of Saitapharnès, a conical, caplike crown of metal has mythological scenes in low relief. It was believed to be a Greek work of the 3d century B.C. until it was exposed as the forgery of a late 19th century Russian goldsmith.

The Romans gave gold crowns with designs of turreted walls or prows of ships for military or naval exploits. They carried the crowns of emperors or victorious generals in front of them in processions, but not even the emperors wore them. The highest honor was the *corona obsidionalis*, originally made of grass plucked on the site and given to the leader who saved a besieged garrison.

Ancient and Medieval.—Byzantine emperors wore either a closed crown or a high pyramidal cap of silk almost covered by pearls and jewels in imitation of the tiara worn by Persian kings. This type with one or two, and later, three bands representing crowns around it became the tiara worn by the popes.

Recessvinto, the 7th century Visigothic king, and members of his family are believed to have given the eight gold crowns dug up near Toledo, Spain, in 1858, to some church. These circular crowns hung by chains from their upper rims are votive crowns. The largest has separate gold letters, enameled red, suspended by chains

from the lower edge which form the words, *Recessvintus Rex Offeret*. These treasures were purchased by the Cluny Museum in Paris, but during World War II the crown of Reccessvinto was given to Spain as a gesture of friendship by the Vichy régime of France.

The Iron Crown of Lombardy received its name from the narrow band of iron on the inside which was long believed to have been made of nails from the True Cross. The six rectangular gold plates on the outside are decorated with repoussé flowerets and with corner designs in blue, white, and translucent green enamels. It is set with cabochon rubies, amethysts, and sapphires. Only six inches in diameter and perfectly round, this is probably a votive crown, possibly Italian work of the 9th century. It was kept in the cathedral at Monza, near Milan, Italy. Napoleon had it carried in a great procession to Milan where he used it when he was crowned king of Italy in 1805. (Fig. 3).

In the Middle Ages there may have been a real crown of iron at Monza. Some emperors of the Holy Roman Empire had three separate coronations: with a silver crown at Aix-la-Chapelle, with an iron crown at Monza, and with a gold crown at Rome. An iron crown was used in the "lay" coronation of Louis the Bavarian in 1328, and later for Charles IV at Monza, and for Charles V at Bologna.

Charlemagne's crown is more properly called the Old German Imperial crown, or the Golden crown, as it was probably made about two hundred years after Charlemagne. It consists of eight gold plaques, semicircular at the top, which are attached to thin iron bands riveted together on the inside. It is octagonal in shape. Four plates with cabochon emeralds and sapphires in filagree settings alternate with plates with designs in enamel. A cross rises above the largest, central section. A single arch springs from behind the cross to the back of the crown. According to an inscription in pearls on the vertical sides of the arch this was added by the German ruler, Conrad III, in the 12th century. The enameled plaques have Latin inscriptions to explain the designs. They represent the Almighty ("Through me kings reign"); Isaiah telling the sick king, Hezekiah, that he will recover and live fifteen more years; David ("The king's strength also loveth judgment"); and Solomon ("fear the Lord and depart from evil"). These figures and inscriptions show the religious significance of crowns in the Christian countries. (Fig. 4).

St. Stephen's crown is venerated in Hungary where during nine hundred years it was used in the coronation of more than fifty kings. No ceremony was considered constitutional without it. Hungarians believe that as long as the crown is safe, Hungary is safe. It is actually two crowns combined to form one. The upper part consisting of two broad straplike arches is what remains of the Latin crown given by Pope Sylvester II to King Stephen about the year 1001 while the lower part, the circlet, is the Greek crown, and was made about seventy-five years later. Both parts are decorated in cloisonné enamel and are made of gold. At the very top is a plaque with a representation of Christ, pierced to fasten a cross, now askew, at the summit of the crown. On each of the four straps forming the arches are two apostles, the other four were undoubtedly there, but were lost

when the lower part of the crown was broken or cut away. When this was made enameling was in its early stages in Italy, and so each of the apostles appears squint-eyed. The lower crown, possibly made in the royal workshops of the Byzantine emperors is only a little later, but the enameling art was more highly developed there. Set between massive jewels, the plaques represent Christ, suitably placed above the circlet in the center front, and below, on either side, the archangels Gabriel and Matthew, beyond them the "warrior saints" Demetrius and George, then the saints Damian and Cosmas, each with his name in blue enamel. Three plaques on the back, inscribed in red, the color of royal signatures in the Byzantine empire, portray the emperor, Michael Dukas VII, with his relative, Constantine, at one side, and Duke Géza I of Hungary at the other. This lower part is known as Michael Dukas's crown because he gave it to Duke Géza. Thus the lower crown symbolized the support the Byzantine emperor gave to a king of Hungary, and the upper crown carried the approval of the pope to an earlier king, St. Stephen. The two crowns were probably combined by King Béla III of Hungary toward the end of the 12th century. Characteristic of Eastern crowns are the short chains, each ending in a trefoil set with polished jewels, which hang from the lower rim, one in back and two at each side.

Hungarian law prohibited the removal of the regalia from the chest in which it was kept, except for coronations, without the consent of the king and Parliament. On the 900th anniversary of St. Stephen's death, in 1938, it was first publicly displayed and scholars had an opportunity to study it closely.

In 1945 the chest in which the regalia had been carefully guarded was delivered by a Hungarian colonel and an escort of twelve soldiers to the United States Seventh Army at Augsburg. When finally opened the crown, scepter, and orb were missing. The colonel admitted he had buried them according to instructions. The next day he had a mud-covered gasoline drum brought from its secret hiding place. When chiseled open, the missing articles were lifted out of three deteriorating leather boxes. When the crown, scepter and orb had been washed and thoroughly dried they were replaced in their rightful box. Later the box was opened and the contents displayed in the presence of army officers and representatives of the press. The box was then locked and sealed with sealing wax bearing the impressions of the dog tags of the Property Control officer. It was taken to Wiesbaden to await its return to Hungary. After 1945 the whereabouts of St. Stephen's crown was kept

secret by the Western powers in order to ensure its safety. (Fig. 5.)

The German Imperial crown also dates from the 11th century. It is formed of eight plaques, semicircular at the top, decorated alternately with a cross in jewels and a heraldic eagle in enamels. The two arches rise to meet under an orb. (Fig. 6.)

Constantine Monomachus and the Empresses Zoë and Theodora are identified from the names accompanying their portraits on seven gold plates decorated in cloisonné enamel. Some archaeologists believe that these, with an eighth plaque now missing, formed a similar crown of the 11th century. Consequently these plaques, kept in the museum in Pest, are sometimes called the crown of Constantine Monomachus.

The crown of Philip II in the cathedral of Namur shows a type worn in the 12th century. Two medieval English crowns are preserved on the Continent. The silver-gilt crown used at the coronation of Richard, brother of Henry III, as king of the Romans in the 13th century, is on the Charlemagne reliquary at Aachen. The other is the bridal coronet worn by Margaret Plantagenet, sister of Edward IV, at her marriage to Charles the Bold, Duke of Burgundy. It has her name inscribed around it: Margarita de York.

The crown of Bohemia was used at the coronation of Charles IV in 1347. (Fig. 7).

The Turkish Vassal crown originally belonged to King Ladislas II of Hungary, and is probably of early Muscovite or Polish workmanship. In 1526 the Turks captured it, hence its name. In 1605 Sultan Ahmed I sent it to István Bocskay, prince of Transylvania, who later gave it to King Matthias. This crown, preserved in Vienna, has a wooden frame covered with silver-gilt plates. It is decorated in niello and set with pearls and precious stones and has an emerald at the top. (Fig. 8).

Modern Crowns.—*Persian.*—A Persian crown of the 17th century is described by Sir John Chardin in his book of travels (1686) as a flat bonnet made of cloth-of-gold with a chimneylike projection sewed onto the top. It was covered with an "embroidery of diamonds" and featherlike ornaments on the rim were set with diamonds, rubies, emeralds, and topazes.

Austrian.—The Austrian Imperial crown, inscribed with the date 1602, is of pure gold set with diamonds. The circlet is banded top and bottom with pearls, the upper rim bears four large fleurs-de-lis alternating with four smaller ones, all set with rubies and pearls. Rising from each side to form a cap is a triangular metal plate with scenes in low relief of the coronation ceremony. These are framed with wide enameled

bands around the opening beneath the arch. The single arch has a large sapphire set on the top.

Scottish.—The Scottish crown was originally a gold band with borders of gold wire, set with 22 large stones, with pearls between them. Above the rim are fleurs-de-lis, crosses and pinnacles. The arches and orb are of French workmanship and were added by James V. The arches have leaves enameled in red and gold, the globe is blue with gold stars, and the cross black and gold set with Oriental pearls and an amethyst. The crimson velvet cap has four large pearls set in gold which show between the arches. In 1707 the Scots feared their regalia might be taken to England. They deposited it in a chest secured by three locks and placed this in Edinburgh Castle in the crown room which had two doors, one of oak and one of iron bars. The keys were hidden and have never been found. One hundred and ten years later the chest was finally opened. Sir Walter Scott who was present wrote that when the regalia was found to be safe the royal flag was hoisted on the castle and the crowd waiting on the hill broke into cheers. He added, "In 1819 the Crown-room having been fitted up, Yeoman-keepers organized and costumed in the fashion of olden days, the Regalia were put on public view." (Fig. 9).

English.—Richard Coeur de Lion's crown was so heavy that he had it supported over his head by two ears. Edward II owned nine crowns of gold and one of silver which were as much his personal property as his cloak. Henry V wore his crown on top of his helmet at the Battle of Agincourt (1415) where it was credited with having saved his life when part of it was chipped off. Henry VIII wore a crown with an arch rising from the sides. Elizabeth added an arch from front to back. In 1625 Charles I pawned part of the royal treasure in Holland to finance a fleet for a disastrous war with Spain. When James II was crowned some of the diamonds for the crown were hired for the occasion and afterwards returned to the jewelers.

In 1649 the Commons, under Oliver Cromwell, ordered the regalia to be totally broken up, the gold and silver melted down and, with the jewels, to be sold to the best advantage of the Commonwealth. This was done. As a consequence all the English crowns are comparatively recent. Some of the old jewels, however, were recovered by purchase or gift and are again set in crowns or other parts of the regalia.

The Black Prince's ruby is one of these. No one knows how it got back, but it is the oldest and most esteemed jewel in the English crowns.

It is an irregularly shaped ballas ruby, about two inches long, and the size of a small hen's egg. It is not cut in facets, but is in its original shape, and highly polished. In 1367 Pedro the Cruel, king of Castile, gave it to Edward of Wales, the Black Prince. The latter wore it sewn to the cap above his coronet. Henry V wore it in his crown at the Battle of Agincourt. When the new state crown was stolen by Col. Thomas Blood in 1671 the ruby must have fallen out, for it was found in his accomplice's pocket when they were caught fleeing from the Tower of London. It was set in the front of the Imperial State crown made for Queen Victoria.

After the destruction of the crowns under the Commonwealth, it was necessary to have new regalia made before Charles II could be crowned. The royal goldsmith was instructed to make a new coronation crown as much like the old one as possible which, like that one, was to be called *St. Edward's crown*. This crown, which is used only in the coronation ceremony, is made of gold. On the circlet are rubies, emeralds and sapphires, each set in a rosette surrounded by diamonds. From the rim rise four crosses alternating with four fleurs-de-lis set with diamonds and other jewels. The two arches are jeweled and are bordered with silver "pearls." The cross has a large pearl at the top and a large pear-shaped pearl hangs from a tiny bracket on each of the arms of the cross. The crown is edged around the lower rim with ermine, and is lined with a purple velvet cap. (Fig. 10.)

The state crown was made for Queen Victoria in 1838. The circlet is of silver openwork. In the front is a diamond weighing just under 310 carats which was part of the *Star of Africa*. On the back is the Stuart sapphire. Between them are clusters of diamonds with emeralds or sapphires in the center. The crosses above the rim are set with brilliants, three have emeralds in the center, but the one in the front of the crown has the Black Prince's ruby. The fleurs-de-lis have rose-cut diamonds and, in the middle, a ruby. The arches are made of oak leaves formed of diamonds with large pearls for the acorns. The orb is covered with diamonds and a large sapphire is set in the center of the cross. The velvet cap is purple and is edged with miniver (or ermine). (Fig. 11.)

The imperial crown of India was made for the coronation of George V as emperor of India at Delhi in 1911 when it was discovered that English law forbids taking the crowns out of the country. It has eight half arches which rise upward to the orb instead of being horizontal or depressed beneath it. It is silver set with dia-

FIG. 11. English State Crown. FIG. 12. Russian crown of Catherine the Great.

monds, the large stones are emeralds and rubies and, in the circlet, some sapphires.

The prince of Wales' crown is gold and has only one arch rising from the sides to meet under the orb. There are no jewels on it. The velvet cap is crimson.

The queen's state crown is silver set with diamonds including the Koh-i-Noor. It has eight arches and the cap is purple velvet. It was made for Queen Mary in 1911.

Russian.—The Russian crown, made for Catherine the Great in 1762 was an open lace-work of diamonds and brilliants with central bands of enormous pearls. It was built up on the sides leaving space in the center, from front to back, for an arch which supported the orb, the globe of which was formed of a single large ruby. (Fig. 12.)

French.—French crowns were surmounted by a fleur-de-lis instead of the orb. The king's crown had four arches rising from the eight fleurs-de-lis on the rim. The dauphin's crown also had eight fleurs-de-lis above the circlet but the four arches were in the form of dolphins.

Coronets.—Like crowns coronets have varied according to country and time. In England the duke's coronet is distinguished by the eight strawberry leaves on the circlet. The marquis' coronet has four strawberry leaves alternating with golden balls. The earl's coronet has eight tall points, topped by a ball, and, between the points, eight small strawberry leaves set close to the rim. The viscount's coronet has sixteen balls on the rim, while the baron's has a total of only six.

MARCIA COTTIS HARTY,
Chief Cataloguer of Art, Metropolitan Museum
of Art, New York.

CROWTHER, krou'thër, Samuel Adjai, Anglican bishop: b. Ochugu, east of the kingdom of Dahomey, about 1809; d. Africa, Dec. 31, 1891. He was the first Negro bishop of the Church of England. He was carried into slavery in 1821, but was freed, with a large company of his countrymen, by a British man-of-war in 1822; was placed in the mission school at Bathurst and was the first student enrolled

in the Fourah Bay College where he subsequently became an instructor. He finished his education in England, where he took orders in the English church in 1843, became a missionary at Akessa and accompanied the first and second Niger expeditions, publishing a narrative of the latter. In 1864 he was consecrated bishop of the Niger and filled that place with honor. He published a dictionary and grammar of the Yoruba language (1852); a primer (1860), a grammar of Nupe, and a translation of part of the New Testament into the Yoruba

CROYDON, municipal and parliamentary borough, England, in County Surrey, 10 miles south of the heart of London, of which it is practically a suburb; near the sources of the Wandle and not far from the Banstead Downs; on the London and Brighton Railroad. It is a place of ancient origin, but its recent rapid increase is due to the overflow of London. The municipal borough includes South Norwood and Thornton Heath. It has important corn and cattle markets and boot and shoe manufactures. It returns one member to Parliament. Of special interest are the remains of the ancient palace. It is the site of London's principal airport. Pop (1939 est.) 243,900; (1949 est.) 252,000.

CROZAT, krô-zâ', a prominent French family of financiers and art collectors. **PIERRE, BARON DE THIERS**: b. 1661; d. 1740, was treasurer to the king and his various acquisitions included 19,000 original drawings, 2,000 engravings, 400 paintings, 1,382 intaglios and cameos and a library of 20,000 volumes. At his death, the collections passed to his nephews, Louis-François, d. 1750; Joseph-Antoine (1696-1740), and Louis-Antoine, d. 1770, who added many beautiful things. The collection of pictures was finally acquired by Catherine II of Russia. Between 1729 and 1742 a finely illustrated catalogue of the collection was published under the title of "Cabinet Crozat."

CROZER THEOLOGICAL SEMINARY, Upland, Pa., (post office, Chester, Pa.). Founded in 1867 by the heirs of John P. Crozer. The school is on a large campus and endowed with buildings and invested funds to the amount of a million dollars. It has a faculty of 9 professors and instructors, an enrollment of 51 students and a plant valued at \$400,000. It is under Baptist auspices.

CROZET, krô-zê, **ISLANDS**, a group of five, in the southern portion of the Indian Ocean, be-

tween Kerguelen and Prince Edward islands, about 1,500 miles off the southeast coast of Africa. They are all of volcanic origin and the most easterly, called East Island, has precipitous cliffs and in the interior lofty peaks, exceeding 5,000 feet. They were discovered in 1772 by the French explorer Marion-Duffresne, accompanied by Crozet, who was the historian of the expedition, and for whom the group was named. The largest island, Possession, was visited by the Challenger expedition in 1873, and is believed to be about 20 miles long by 10 broad. The total area of the group is about 200 square miles. The archipelago is a dependency of Madagascar, which became a French colony in 1896; in 1925 the islands were made a national park. Rabbits released there have survived, but there are no permanent human inhabitants.

CROZIER, krō'shēr, John Beattie, English philosophical writer: b. Galt, Ontario, Canada, April 23, 1849; d. London, England, Jan. 8, 1921. Educated at Toronto University, in 1872 he began the practice of medicine in London, where he also studied philosophy and economics. His first publication to attract attention was *Civilization and Progress* (1885). The *History of Intellectual Development* (1897-1901) earned him a Civil List pension. He wrote an autobiography, *My Inner Life* (1898); *The Wheel of Wealth* (1906); *Sociology Applied to Practical Politics* (1911); and *Last Words on Great Issues* (1917).

CROZIER, William, United States army officer: b. Carrollton, Ohio, Feb. 19, 1855; d. Washington, D.C., Nov. 10, 1942. Graduating from the United States Military Academy in 1876, he served for three years in the West against the Sioux and the Bannock Indians; was instructor of mathematics at West Point 1879-1884, when he entered the ordnance department, commissioned captain in 1890. He invented a wire-wound gun, and with Gen. Adelbert R. Buffington, a disappearing gun carriage. During the Spanish-American War he was inspector general for the Atlantic and Gulf coast defenses; was in the field in the Philippines in 1900; chief ordnance officer of the Peking relief expedition (1900); and president of the Army War College (1912-1913). In World War I he was appointed chief of ordnance with the rank of brigadier general; in 1917-1918 he was a member of the Supreme War Council, which arranged pooling of ordnance for all the Allied armies. After serving as commander of the northeastern department of the United States Army in 1918, he retired from active service. He published *Ordnance and the World War* (1920). His *Notes on the Construction of Ordnance* was used as a textbook in schools for officers. He was buried in Arlington National Cemetery.

CROZIER, William John, American professor and scientist: b. New York, N. Y., Aug. 28, 1892. Educated at the College of the City of New York and at Harvard, he won a traveling fellowship 1915-1918, which he spent at Bermuda Biological Station for Research. Becoming chairman of the Relief for Belgium Educational Foundation in 1934 he was also a visiting lecturer to Belgian universities and Lowell lecturer at Harvard. In World War II he was operations analyst to the United States Army Air Force (1944-1945). He has been co-editor of the *Journal of General Physiology* since 1924

and a member of the editorial board of the *Journal of General Psychology*, and has written a monograph on experimental biology. He is an authority on marine zoology; adaptation; animal behavior; irritability; temperature characteristics; and the central nervous processes in vision.

CROZIER, William Percival, British newspaper editor: b. Stanhope, County Durham, England, 1879; d. Manchester, April 16, 1944. Educated at Trinity College, Oxford, he joined the *Manchester Guardian* in 1903, was director of the *Manchester Guardian and Evening News* from 1921; and from May 1932 was editor of the *Guardian*. He was noted for his liberal viewpoint and his support of the oppressed, carrying on the traditions of his famous predecessor Charles Prestwich Scott. He published *Letters of Pontius Pilate* (1928); and contributed to J. L. Hammond's *Life of C. P. Scott* (1934).

CRUCIBLE. See CHEMICAL APPARATUS.—*Quantitative Analysis* (Gravimetric).

CRUCIFERAE. See BRASSICACEAE.

CRUCIFIX. See CROSSES AND CRUCIFIXES.

CRUCIFIXION. The history of crucifixion as a mode of punishment for crime must be studied as a part of the Roman system of jurisprudence rather than of any Eastern system, Asiatic or Grecian. Greece and Asia had indeed from very early times occasionally resorted to it; but the practice did not become universal. The Hebrews, for example, adopted or accepted it only under Roman compulsion: under their own system, before Palestine became Roman territory, they inflicted the death penalty by stoning. At Rome, however, from the period of the Republic until the 4th century (when Constantine, in memory of the Passion of Jesus Christ, abolished this form of punishment) it was customarily inflicted upon slaves found guilty of denouncing their masters. Provincial brigands might also be crucified, but the crucifixion of a Roman citizen was never permitted by law.

CRUCIFIXION IN ART. The Crucifixion symbolizes the triumph of Christ and the doctrine of Redemption, yet appears in art only long after the abolition of this degrading punishment. Early representations are disguised, as a dolphin around an anchor, a lamb on a cross, or Christ as orant (arms outstretched in prayer).

The first real scene is in the Rabula gospels, painted in the monastery at Zagba, Mesopotamia, in 586. A nimbused, living Christ, wearing a long tunic, is attached by four nails. Above are the inscription, sun, and moon; below, centurion with lance, soldier with sponge, three dice-playing soldiers, suppliant Mary, gesturing John holding a book, three holy women. Symbolism is giving way to realism through gesture and facial expression. This scheme persists until about the 12th century.

The Crucifixion is rarer in the West, the earliest certain representation being the nude Christ at Narbonne described by Gregory of Tours about 593. Such realism shocked the faithful, and by the 8th century the clothed Christ is standard in both East and West.

For some time there are only variants on this theme. In the period of the Carolingians and the

Ottos of the Holy Roman Empire are added the Evangelists, Adam and Eve, church, and synagogue. In Italy the partially nude Christ appears. The hand to cheek gesture of Mary and John, expressive of sadness, continues in the West into the Renaissance, though the East returns in the 11th century to the unemotional representation. These innovations continue primarily in Romanesque crucifixes. National differences arise but Christ the triumphant Redeemer, sometimes crowned, is usually maintained.

In the 13th century, inspired by mystics like St. Francis, a new concept arises in the West—the human drama of the Crucifixion. Christ is dead or suffering, His body hanging or contorted by the crossed feet pierced by one nail. The regal crown is replaced by the crown of thorns. Mary collapses with grief. To this, Giovanni Cimabue adds crowds of people, a scheme continued in the 14th century by Giotto di Bondone and later elaborated. The trend toward increased agony has the Magdalen clutching the cross, angels weeping as they catch the blood.

Renaissance iconography changes little but tends to free Christ from the throng, to represent Him as a perfect man, thus reemphasizing the mystery and triumph of the Redeemer. The tortured Christ continues in some northern regions in the Baroque period.

In general the nude Christ, crowned with thorns, head inclined, attached with three nails, continues to the present day. Compositional and emotional elements vary according to the artist's temperament and the taste of the period.

MARGARET A. ALEXANDER.

CRUDEN, krōō'd'n, **Alexander**, Scottish bookseller and scholar: b. Aberdeen, Scotland, May 31, 1701; d. London, England, Nov. 1, 1770. Educated at Marischal College, Aberdeen, with a view to the church, he early showed signs of insanity, which recurred at intervals during his life. He became a private tutor, but not succeeding in this profession, he went to London in 1732 and opened a bookseller's shop. Influential friends obtained him the title of bookseller to Queen Caroline. Confined to a madhouse for a few months, he escaped and wrote an account of his experience, sued for damages, and then published a pamphlet on the unsuccessful trial. As corrector of the press for classical works he was very accurate, but this work seems to have increased his insanity, for he now believed himself to be divinely appointed as Corrector of the People, and he wrote and preached and petitioned to obtain such a post. After another brief confinement he published in a magazine *The Adventures of Alexander the Corrector*.

In spite of his aberrations he completed by 1737 his great lifework, *A Complete Concordance to the Holy Scriptures of the Old and New Testament* . . . compiled with great industry and accuracy. The 1824 edition of the *Concordance* contains a biography of him by Alexander Chalmers.

CRUDEN, parish, Scotland, in East Aberdeen. It is the fishing port for Cruden Bay on the North Sea, 7 miles south-southwest of Peterhead. During the summer it is a seaside and golfing resort; the golf course, called the Ward of Cruden, lies along the sands and at its northern end is the fishing village of Port Erroll. Slains Castle, now a ruin, was once the seat of the earls

of Erroll, hereditary high constables of Scotland. James VI of Scotland destroyed it in 1594. Pop. (1951 est.) 2,294.

CRUDES. See **CHEMICAL INDUSTRIES**.—*Petroleum Products*.

CRUELTY, in law, has no narrowly defined or technical meaning, but is a generic term applicable to all categories of wilful mistreatment, particularly the infliction of unjustifiable physical pain or suffering. Cruelty to animals was not a crime under the early common law, but at the present time statutes in both England and the United States make it a criminal offense to torture or torment living creatures. Among other acts which are unlawful are wilful or wanton injury, neglect, or purposely inflicted ill treatment. Many states have societies for the prevention of cruelty to animals, which are frequently supported by public funds to some extent and which sometimes have limited power to enforce the laws on this subject. Cruelty to children is punishable not only by criminal action but by removal of the mistreated children from the custody of parents, guardians and others who are guilty of abusing them. Depending on the wording of the particular statute involved, cruelty may include the failure to furnish food, clothing, shelter or medical care, as well as the infliction of physical abuse. In the law of domestic relations, cruelty may be a ground for either separation or absolute divorce. As a general rule, the question of what constitutes cruelty depends on the facts of the particular case. Among the acts which may be considered by the courts as cruel treatment are conduct endangering physical safety and health, certain kinds of verbal abuse, and the infliction of mental suffering. See also **DESERTION**.

RICHARD L. HIRSHBERG.

CRUIKSHANK, krōōk'shāngk, **Ernest Alexander**, Canadian soldier and historian: b. Welland County, Ontario, Canada, June 29, 1853; d. Ottawa, June 23, 1939. Educated at Upper Canada College, he farmed for a time in Ontario, becoming warden of Welland County in 1886. He had joined the militia in 1877, and rose by 1915 to the rank of brigadier general. After seeing service in World War I he became director (1918-1921) of the Historical Section of the General Staff at Ottawa, when he retired. From 1919 until his death he was chairman of the Historic Sites and Monuments Board of Canada. His writings include papers for the *Transactions* of the Royal Society of Canada, the *Papers and Records* of the Ontario Historical Society, and others. His books on early Canadian history include *Battle of Lundy's Lane* (1889; 3d ed., 1894); *Battlefields of the Niagara Peninsula* (1891); *Battle of Fort George* (1896); and he edited *Documentary History of the Campaign on the Niagara Frontier, 1812-1814*, 9 vols. (1896-1908). Later he wrote a *History of the Great War* (1920); *The Life of Sir Henry Morgan* (1935); and *The Political Adventures of John Henry* (1936).

CRUIKSHANK, **George**, English illustrator and caricaturist: b. London, England, Sept. 27, 1792; d. there, Feb. 1, 1878. Family necessities compelled him when still a child to produce what he could, and the want of careful preliminary study at his outset in art affected his

productions through a great part of his career. Hence his defects were chiefly those of taste, and these have resulted in his being popularly ranked somewhat lower as an artist than his merits deserve. His drawing was always faithful, precise and felicitous, his facility amazing and his invention inexhaustible. The catalogue of his productions prepared by the keeper of the prints in the British Museum comprises 5,500 articles, many of them recalling Rembrandt's work by their richness in light and shade. The earliest of his known drawings is dated 1799, when he was only seven years of age, and when 15 he was comparatively distinguished. His first occupation was designing illustrations for children's books and popular songs. He contributed to *The Scourge* and *The Meteor* and at about the same time made sketches referring to the trial of Queen Caroline. In 1837 Cruikshank commenced in *Bentley's Miscellany* his famous series of etchings on steel illustrating Dickens' *Oliver Twist*, full of pathos, humor and tragic power; the illustrations for the *Waverley Novels*; and 15 plates for *Don Quixote*. Having connected himself with the temperance movement he produced the *Bottle*, a powerful series of designs, characterized, from its subject and the artist's object, by inevitable vulgarity, but pregnant with genius and high moral teaching. In 1830 he tried to paint and while he could not handle his tools well, he nevertheless displayed here as elsewhere his keen sense of caricature. Of these efforts the best are two: *Cinderella* in the South Kensington Museum and *The Worship of Bacchus* (National Gallery). In spite of his genius, industry and homely mode of life he never succeeded in acquiring a competency and was compelled in extreme old age to depend on the aid of his admirers. His true life-work consisted in illustrating the costume, manners and vices of the people for a period of considerably more than half a century.

(London 1882); Stephens, Frederic George, *A Memoir of George Cruikshank* (London 1891); and Chesson, Wilfrid Hugh, *George Cruikshank* (London and New York 1908); Cohn, Albert Mayer, *Bibliographical Catalogue of the Printed Works Illustrated by George Cruikshank* (London 1914); also *Cruikshank's Water-Colours* (London 1903).

CRUISER, an armed vessel of high speed, considerable gun power, and long cruising radius. Also the name given to a motor yacht fitted with living accommodations. Privateers (q.v.) were called cruisers in the 18th century. By the year 1800 the name was generally applied to frigates (q.v.). The British Navy evolved a cruiser type from fast dispatch vessels, and completed the *Shannon* in 1877. The United States Congress appropriated funds for three cruisers in 1883, *Chicago*, *Atlanta*, and *Boston*. In 1886 the German Navy had ships called frigate-built cruisers. Types of cruisers include: *Armored* cruisers having side armor and an armored deck; *Protected* cruisers having an armored deck but no side armor; *Belted* cruisers having a belt of armor around the water line and an armored deck; *Scout* cruisers having no armor, light armament and very high speed; *Battle* cruisers having fewer heavy guns than a battleship, less armor and much higher speed. Treaties for the limitation of naval armament in 1922 and 1930 affected cruiser design. The United States Navy developed new types of cruisers: *Heavy* cruisers (CA) with 8-inch guns; *Light* cruisers (CL)

with 6-inch guns; *Anti-Aircraft* cruisers (CLAA) with high-angle 5-inch guns; and *Large* cruisers (CB) with 12-inch guns. In June 1954 the United States had in commission 14 CA, 3 CL, and 1 CLAA; in the Reserve Fleet 2 CB, 13 CA, 30 CL, and 8 CLAA. See also UNITED STATES—United States Navy; WARSHIPS, MODERN.

CRUMMELL, Alexander, American colored Episcopal clergyman: b. New York, March 3, 1819; d. Point Pleasant, N. J., Sept. 9, 1898. His father was a native African and his mother a free woman. He received his education at the Oneida Institute and in 1839 applied for admission to the General Theological Seminary. His request was refused owing to the intense prejudice against the higher education of the Negroes. He accordingly went to England in 1849 and graduated at Cambridge University in 1853. He engaged in missionary work in Liberia 1853-1873, when he went to Washington, D.C., and founded Saint Luke's Church, of which he was rector until 1895. In 1897 he organized the American Negro Academy in New York. He published *The English Language in Liberia* (1861); *The Future of Africa* (2d ed., 1862); *The Negro Race Not Under a Curse* (1863); *The Greatness of Christ, and Other Sermons* (1882); *Africa and America* (1891).

CRUSADE, Children's. See CHILDREN'S CRUSADE, THE; CRUSADES.

CRUSADES (Portug. cruzado, "marked with the cross"), the military expeditions which were sent out by the Christian peoples of the West from the end of the 11th till the latter half of the 13th century for the conquest of Palestine. From the earliest times pilgrims had gone to what, because of Christ's life therein, was called the Holy Land. In 637 Palestine fell into the hands of the Mohammedans, but, though several churches were turned into mosques, Christians were allowed full liberty to come to the holy places in Jerusalem for nearly four centuries. In 969 the Fatimite dynasty extended its rule over Egypt and Palestine, and with this change of rulers there came an end of the cordial relations. The insults, and even injuries, that Christian pilgrims suffered aroused bitter feeling in the West. Finally Pope Silvester II (999-1003), one of the best known of the medieval popes and famous for his very practical character, issued a call for volunteers for the purpose of freeing the Holy Land. His summons met with no success. In 1073 Palestine came under the control of the Seljukian Turks and the conditions there became even worse than before for the Christians. Pope Gregory VII (Hildebrand), in 1074, asked the Western nations for help for their suffering brethren in the East and even suggested to the German emperor, Henry IV, that it would be easy to raise an army of 50,000 for the rescue of the Holy Land from the hands of unbelievers. The idea of the crusades that had thus been incubating in Western minds for nearly a century did not come to fruition until 1095, when the awful state of affairs that Christian pilgrims had to encounter in the Holy Land became unbearable. Peter of Amiens, surnamed the Hermit, saw the terrible situation while on a pilgrimage to the Holy Sepulcher, succeeded in arousing the interest of Pope Urban II and obtained permission to preach a crusade.

The first great cause of the Crusades, then, was the earnest desire to free the Holy Land. It seemed to the medieval Christians to be a question of the maintenance of their religious honor that the infidel should not be allowed to occupy the holy places. Other causes conspired to produce action just at this period. It was felt by Western rulers, and especially by the popes, that unless the Turks were repressed in the East, they would gradually acquire irresistible power and eventually invade the West, with hope of success.

For the lower classes in the West, on the other hand, life had become almost intolerable because of the oppression of the nobles, the frequent wars and the almost servile duties that feudalism enjoined. In addition to other causes of dissatisfaction, the harvest had practically failed in the West for several years and the year 1095 proved to be a particularly bad year for farmers; many of those dependent on the land and its products suffered severely from famine. These material difficulties predisposed the people to risk all in the hope of betterment. There was little chance to rise in the West and the vague opportunities of distant war seemed to promise much. Besides, the spirit of chivalry had come in and many of the nobles devoted themselves to the cause with the idea that they would thus win favor of the heavenly queen, the mother of the Lord, whose life had been lived in Palestine and whom they had chosen for their patroness. Devotion to the Blessed Virgin also caused women to urge their husbands, brothers and other male relatives to join in the holy war for the Christian possession of her home at Nazareth.

It needed only the intimation of authority to precipitate an Eastern expedition and that came very naturally from the popes as the acknowledged spiritual heads of Christendom. Pope Urban II, having heard Peter of Amiens' story of Christian suffering in the Holy Land, summoned a council to meet at Piacenza in 1095 and gave Peter the opportunity to address the multitude, which assembled in such numbers that he had to talk in the open air. In November 1095, ambassadors from all the nations were present at a council at Clermont, where Peter's words had so much power that with one voice the multitude called out "God wishes it," and this became the slogan of the Crusade.

First Crusade.—In 1096, a number of armed bodies set out in different divisions. Many of these hosts were unamenable to military discipline, and, being unprovided with even the necessities for such an expedition, were almost completely destroyed in the different countries through which they had to pass before reaching Constantinople, which had been chosen for their place of meeting. Only a few stragglers found their way home again or succeeded in maintaining themselves for a time until the arrival of the more regularly organized bodies of troops which set out the next year. With these were most of the distinguished men whose names are associated with this first great chivalric effort to redeem the Holy Land from the infidel. At the head of nearly 100,000 men were Godfrey of Bouillon, duke of Lower Lorraine; Hugh of Vermandois, brother to Philip, king of France; Baldwin, brother of Godfrey; Robert II of Flanders; Robert of Normandy, brother of William II, king of England; Raymond of Toulouse; Bohemund I of Otranto, son of Robert Guiscard; Tancred, cousin of Bohemund; and other heroes.

Tancred is the hero of whom so many poets have written. He was what Chaucer called "a verray parfit gentil knight." This First Crusade later formed the subject of Torquato Tasso's *Jerusalem Delivered* (1575), which owed a great deal of its interest to the fact that it was written while the victory at Lepanto (1571) was fresh in the mind of the poet and still well remembered by his readers, for, while the Crusades are considered to end with the last quarter of the 13th century, the gathering of the naval force under Don John of Austria that overcame the Turks was really the result of the crusading spirit.

The various armies of the First Crusade gathered at Constantinople about Christmas 1096. Here they were delayed for some time by the diplomacy of the Greek emperor, who wished to be assured that the immense forces which had come partly as the result of his own request for aid would not prove the ruin of his tottering empire. About Pentecost, 1097, the Crusaders crossed over to Asia by the Strait of Gallipoli, and their first conquest was the town of Nicaea in June 1097. Shortly after this, on July 4, the Crusaders met an Eastern army in pitched battle for the first time, at Dorylaeum (now Eskişehir) and put it to flight. The crusading legions now marched through Asia Minor until they reached Antioch. They would probably have been long delayed in the siege of this town but for treachery which threw it into their hands in June 1098. The citadel, however, remained in possession of the Turkish garrison. Before the Christians captured it, they themselves had to stand siege in Antioch from a Turkish army which surrounded the town soon after its capture. After three weeks of siege the Crusaders were reduced to a very pitiable condition, but on June 28 they made a vigorous sortie and succeeded, in spite of their famished and exhausted condition, in completely routing the Turkish besiegers.

The Crusaders remained nearly a year in the neighborhood of Antioch and only in May 1099 was the march against Jerusalem begun. The siege of the city was commenced early in June. Finally, after six weeks of a fierce siege, the city was captured by a two days' storming, on July 15. Godfrey of Bouillon was chosen king of Jerusalem, but humbly refused to wear the king's crown on the spot where the Saviour of the world had worn a crown of thorns. He accepted as his designation instead of king that of Defender of the Holy Sepulcher. After scarcely a year of sovereignty, however, he died in 1100 and was succeeded by his brother Baldwin. Baldwin had separated from the main army of the Crusaders while it was in camp in the neighborhood of Antioch and had proceeded to Edessa (Urfä). This city was in possession of a Christian prince, who was able to maintain himself only with difficulty against the Mohammedans. Baldwin concluded a treaty by which he agreed to aid this prince against the Mohammedans on condition that he himself should be his successor on his death. This treaty was made in February 1098, and, as the Prince of Edessa was killed soon after in a popular insurrection, Baldwin asserted effectually his claims to succeed him and soon made himself ruler of an extensive territory stretching even beyond the Armenian Mountains and the plain of Mesopotamia. He was accordingly his brother's natural successor as the ruler in Palestine.

Second Crusade.—In 1144 the Saracens re-

captured Edessa. This produced great consternation throughout Europe, because it was feared that the other acquisitions made by the Christians during the First Crusade would also fall once more into the hands of the infidels. As a result, Pope Eugenius III called upon Saint Bernard of Clairvaux to preach the Second Crusade. The two leaders of the expedition were the German emperor, Conrad III, and the king of France, Louis VII. They collected about 140,000 men and in 1147 led them to the East. This Crusade was entered upon with great enthusiasm. It is recorded that after Bernard's sermon the demand for cloth crosses—used as a sign of the wearer's promise to go on the Crusade—so exceeded the supply provided that Bernard had to cut up his own garments to help meet the shortage. In spite of such fervor, however, the army failed in its purpose of recapturing Edessa, and indeed only served by its presence still further to weaken the already almost tottering kingdom of Jerusalem. The crusading armies returned to Europe in 1149, and it was nearly 50 years before any other attempt was made to diminish the dominion of the Saracens.

Third Crusade.—In 1187 Saladin took Jerusalem from the Christians and the zeal of the West blazed out once more. The three principal monarchs of Europe, Frederick I (Barbarossa), emperor of Germany; Philip II, king of France; and Richard I (Cœur de Lion), king of England, offered to assume the cross and to lead their armies in person against the Saracens. Frederick's army succeeded in reaching the Holy Land only after having overcome an immense Turkish army at Philomelion (Aksehir) on May 7, 1190. Not long after his victory, Frederick was drowned in the river Calycadnus (Göksu) and this took all the spirit out of his troops. His son Frederick led the army to the siege of Acre, but after his death, in January 1191, the German army abandoned the expedition. Philip and Richard agreed to unite their forces at Messina, in Sicily. Here they stayed until the spring of 1191. Philip reached the Holy Land on the day before Easter and joined the other Crusaders before Acre. Richard's fleet was dispersed by a violent storm and his wife and mother were detained as prisoners on the island of Cyprus, to which their vessel had been driven, by Isaac Comnenus, the heartless, despotic ruler of the island. On Richard's arrival from Rhodes, where his vessel had been compelled to put in, he succeeded in taking Isaac and his daughter prisoners and had himself proclaimed king of Cyprus. It was not until the beginning of June that he joined the French at Acre. Owing to jealousies between the two monarchs, the French king abandoned the expedition shortly after the fall of Acre.

Richard succeeded in many wonderful exploits against the Saracens, but was not able to accomplish much in regaining territory. He did not succeed in recapturing Jerusalem, and, though he defeated Saladin at Azooz and captured Joppa (Jaffa) he at last despaired of the capture of Jerusalem and made a truce with Saladin by which the seacoast from Tyre to Joppa remained in the possession of the Crusaders, and Christians were allowed full liberty to visit the Holy Sepulcher.

Fourth Crusade.—The Fourth Crusade was due to the zeal of Pope Innocent III. Its chief promoters were Thibaud of Champagne, Baldwin, Count of Flanders, and Enrico Dandolo, the old

doge of Venice. Boniface III, Count of Montferrat, was chosen leader of the expedition. The Crusaders assembled at Venice in 1202 and were induced by Dandolo to attack Zara in Dalmatia, a town which had formerly belonged to the Venetians but which had renounced its allegiance. This relegation of the religious motive to a secondary position in favor of Venetian commercial interests exemplified the underlying spirit of the Fourth Crusade. The capture of Zara was contrary to the wish of the pope, who excommunicated the Crusaders for their failure to fulfil their vow of proceeding to the Holy Land. News now came to the Crusaders' camp that there was a revolution in Constantinople and their aid was asked for one of the claimants to the throne. Dandolo seems to have been mainly responsible for encouraging the Crusaders to accept the invitation to proceed to Constantinople. The Crusade was thus entirely diverted from its original purpose and became an attack on the Byzantine Empire. Constantinople was seized and pillaged in 1204 much to the apparent consternation of the pope, but a Latin empire was established and Baldwin IX of Flanders became first emperor. Asked by the conquerors to ratify the subjugation of the Greek Byzantine empire and union with the Western Church of the schismatic Eastern, Innocent perforce acquiesced. But his hopes for a Crusade from Constantinople were disappointed; it soon became apparent that the new Latin rulers must devote all energies to maintaining their hegemony over hostile Greeks.

Children's Crusade.—The failure of so many expeditions to the Holy Land proved very discouraging and people began to wonder if there was not some cardinal fault in the make-up of the parties that went on the Crusade. It began to be said that the Holy Land would never be captured, except by those who were innocent. Accordingly, when Stephen, a French peasant boy, in June 1212, began to preach a children's crusade, he made many converts to his opinion that possibly children might accomplish what adults had failed in. Some 30,000 French children are said to have taken part in the expedition. A like movement began in Germany and soon proved to have almost as great a following. Over 20,000 German children crossed the Alps into Italy. Both expeditions, as might have been expected, came to grief. The French children were tempted on board vessels by designing slave merchants in Marseilles, and many of them were sold into slavery. Many of the German children lost their lives through the hardships they had to endure on the march. Some were lost at sea and some settled down here and there throughout Italy.

These expeditions represent a phase of that tendency to psychic contagion that sometimes comes over even intelligent people in an inexplicable way, and it is from this standpoint that they have been very much discussed in recent years. The Children's Crusade corresponds to the witch baiting of more modern times, or to some of the many spiritual manifestations of older periods. Some doubts have been thrown on phases of the history of the Children's Crusade, as for instance the fate of the French children, but there seems good reason to believe the account given here to be correct.

Fifth Crusade.—After an interlude of five years after the Children's Crusade, a Hungarian expedition went to Egypt and captured Dami-

few to many segments. In the higher members, the cephalon is usually fused to one to eight, generally eight, of the succeeding trunk segments to form the cephalothorax and the remaining trunk segments then constitute the abdomen.

The external surface of a crustacean consists of hardened material, constituting the exoskeleton, secreted by the underlying epithelium or epidermis. This exoskeleton is composed of layers of a flexible substance of carbohydrate nature termed chitin, usually reinforced and hardened through impregnation with lime salts, whence the name Crustacea. At segmental boundaries and the joints of the appendages the exoskeleton is thinner and more flexible than elsewhere to permit movement. However, the exoskeleton does not allow of very much growth; hence, the Crustacea moult at intervals. The old exoskeleton splits along the back and the animal pulls itself out of the old shell; and being now quite soft, expands considerably before the new exoskeleton (performed under the old one) sets and hardens. During this time, the animal is in the «soft-shell» stage and, being then susceptible to injury, usually retires to a secluded place. The Crustacea lack a true internal skeleton but the exoskeleton sends projections and folds into the interior to serve as attachment points for muscles.

In many Crustacea, the exoskeleton extends from the head region backwards as a hoodlike or bivalved free fold, termed the carapace, that covers part or all of the body, acting as an additional protection. The space thus formed between the body wall and the carapace may serve as a brood-chamber in which the eggs develop or may form on each side a branchial chamber in which the gills are accommodated.

Appendages.—The Crustacea are provided with leglike appendages that depend from the ventral surface of the body. Primitively each body segment bore a pair of appendages that were alike throughout the body length but at present appendages are often lacking from some body regions and present a great variety of form and function in different regions and in different crustaceans. The type of appendage present on a given body segment or body region does not necessarily correspond in different crustaceans. The crustacean appendage through all of its variations is classifiable into two fundamental types: the *foliaceous* and the *biramous*. The foliaceous type (Fig. B) is thin, flat, more or less lobed, and leaflike, employed chiefly in swimming and in maintaining a respiratory current. The biramous type (Fig. A), chiefly locomotory, consists of a basal piece or protopod bearing a pair of projections, an outer exopod and an inner endopod. Primitively the exopod and endopod are alike (Fig. A) but often they are altered in different directions for varied functions. Through loss of one of the projections, usually the exopod, the biramous appendage is converted into the uniramous type (Fig. D), seen in walking and grasping legs. All transitions exist between foliaceous, biramous, and uniramous appendages. Formerly the foliaceous type was considered the more primitive but present opinion inclines to regard the biramous as the original form of the arthropod appendage.

In general, the Crustacea have the following appendages (Fig. D). The cephalon bears two

pairs of antennae (of which the anterior pair is often termed antennules), long, slender, jointed feelers, heavily provided with tactile and chemical sense organs. In some of the very small Crustacea and in larvae they may also serve as swimming organs; thus in the Copepoda (Fig. C), the antennules, and in the Cladocera (Fig. E), the antennae act as swimming oars that by their strokes impart to the animals a characteristic jerky movement. Following the antennae come a pair of hard mandibles or jaws for chewing and two pairs of foliaceous appendages, the first and second maxillae, assisting in testing food and passing it into the mouth. Mandibles and maxillae occur at or behind the mouth opening and are collectively termed mouth parts. The head also bears eyes, chiefly in the form of a lateral pair, often mounted on movable stalks. These eyes are considered by some authorities to be true appendages and to represent an otherwise undistinguishable segment but this view is not generally accepted. Leaving out of consideration a possible eye segment, the cephalon then, as judged by its appendages, consists of five segments plus an anterior unsegmented head piece. Following the head region, the trunk may bear a series of similar foliaceous swimming appendages as in the fairy shrimps (Fig. G) and other phyllopods (see PHYLLOPODA); but more commonly, especially in the higher Crustacea or Malacostraca there follow on the mouth parts one to three, typically three, pairs of maxillipeds, biramous appendages intermediate between maxillae and walking legs, that really belong to the thorax but assist the mouth parts in testing, seizing, and mincing food. Behind them come usually walking legs, long, hard, jointed uniramous appendages, typically five pairs in the Malacostraca (Fig. D), which then have eight pairs of thoracic appendages or a total of 13 pairs for the entire cephalothoracic region. The two terminal joints of the first pair of walking legs may be enlarged and opposable after the manner of thumb and first finger to form a formidable claw, as in lobsters and crabs. The abdomen may lack appendages as in phyllopods and copepods but in the Malacostraca bears six pairs of biramous swimming feet, known as pleopods, the last pair of which may be greatly enlarged and broadened to form the uropods. These act together with the telson to form a powerful swimming fan that by a forward or flexor stroke drives the animal backwards. The last body joint, termed the telson, bears the anus and is devoid of appendages in higher Crustacea but may bear a pair of bristly projections, the furcal rami or cercopods, in lower types, as phyllopods and copepods (Fig. C). The telson is usually considered not to represent a segment but is regarded as a tail piece, corresponding to the head piece. There are then in the higher Crustacea six abdominal segments or a total of 19 for the entire body.

Very commonly some appendages are modified for sexual purposes. Any appendages may be so altered and the ones involved do not correspond in different groups of Crustacea. Thus in the male certain appendages may act as claspers to hold the female during mating, as the enlarged second antennae in fairy shrimps (suborder Phyllopoda, Fig. G), the antennules in Cyclops and other members of the order Copepoda (Fig. C), the enlarged terminal joints of some of the thoracic legs in the orders Amphipoda and

FIG. D. Schematic representation of a malacostracan crustacean, seen from the side. 8, antennule; 9, antenna; 12, cephalon; 13, thorax; 14, abdomen; 15, telson; 16, mandible; 17, first maxilla; 18, second maxilla; 19, first maxilliped; 20, second maxilliped; 21, third maxilliped; 22, walking legs, uniramous type; 24, pleopods, biramous type; 25, uropods, or last pair of pleopods.

Isopoda. Again, certain male appendages may be adapted for transferring sperm to the female as in the order Decapoda where the first or first two pairs of pleopods are modified into hard grooved structures for this purpose. Among females, modification of appendages occurs for attachment of eggs or to form a brood chamber in which the eggs develop.

Asymmetry among the appendages is of common occurrence, as the claws of the lobsters, one of which is a heavy crushing claw, the other a more elongate snapping claw. In the hermit crabs one claw is larger than the other and is employed in closing the mouth of the shell when the animal withdraws. An extreme case is seen in the male fiddler crab where one claw is of enormous size relative to the body; it is employed in courtship and fighting. These asymmetries are not linked to a particular side of the body, and the condition in a given individual can be reversed through regeneration experiments.

Muscular and Nervous Systems, and Sensory Organs.—The Crustacea have a well-developed muscular system beneath the epidermis, consisting of segmentally arranged bundles in the body region and flexor and extensor pairs in the appendages. The muscle fibers are of the striated type with a complicated microscopic structure comparable to that of vertebrate muscle fibers.

The nervous system is fundamentally of the ladder type, consisting of a pair of cords that bear primitively a ganglionic enlargement in each segment and are united at the ganglia in each segment by a transverse commissure like the rung of a ladder. However, in all except a very few of the lower Crustacea, the two cords are so closely approximated that the ladder arrangement is not evident and generally there are fewer ganglia than segments because of fusions among the ganglia. The cords begin with a pair of cerebral or brain ganglia situated above the digestive tube at the anterior end of the body but these are really compound ganglia

composed of the fused antennular and antennal ganglia and the optic lobes. The cords then continue as a pair of commissures encircling the beginning of the digestive tube below which they unite to form the apparent second pair of ganglia, the subesophageal ganglia, that also constitute the first ganglia of the ventral cords. The subesophageal ganglia are also compound consisting of the fused ganglia of the segments to which the mouth parts and maxillipeds belong. The nervous system then continues as the ventral cords lying in the midventral line close to the body wall, and presenting a variable number of ganglionic enlargements. The Crustacea also possess something approximating the vertebrate sympathetic system, a special set of nerve fibers supplying the heart, digestive tract, and other viscera.

The Crustacea are richly supplied with tactile and chemical sense organs in the form of sensory hairs, bristles, etc., located upon appendages and also on the general body surface. Two kinds of eyes occur, the unpaired median eye and the paired lateral eyes. The former is of the pigment cup type, consisting mostly of three such cups fused together, and occurs in the larval stage, hence often called the nauplius eye, and in some adults. The lateral eyes, similar in structure to the compound eyes of insects, are the type usually found in adult crustaceans; they may fuse to form a single median eye as in *Daphnia* and others. A static organ or organ of equilibrium occurs in the higher Crustacea imbedded in the antennae or other appendages. It consists of a small chamber containing one or more hard bodies or rock grains that rest upon sensory hairs. Movement of the bodies against the hairs gives the animal information as to its orientation. The Crustacea are devoid of organs of hearing but presumably can detect vibrations.

Digestive, Circulatory and Reproductive Systems.—The Crustacea in general lack a true body cavity or coelom. The interior space of

their bodies in which the digestive, circulatory, and reproductive systems lie is a blood space or haemocoel and is filled with blood. The Crustacea did originally have a coelom but this has been crowded down to a few small spaces by the expansion of the blood system.

The mouth is situated on the ventral surface of the head region and opens into a simple, mostly straight digestive tube that runs to the posterior end there opening on the telson by way of an anus. The fore part of the digestive tube may be enlarged into a grinding stomach that may be provided with strong chitinous teeth for grinding and hairs for sifting food. Attached to the middle part of the digestive tube there is often a pair of large glands, variously termed liver, hepatopancreas, and midgut glands. These play an important role in secreting digestive enzymes, absorbing the products of digestion, and storing excess food supplies, chiefly as fat.

The circulatory system belongs to what is known as the open type, i.e., there are no capillaries or definite veins but the blood from the arteries flows into large body spaces from which it slowly returns to the heart. The heart, situated in the middorsal region, is often quite elongated and may show segmental structure; its wall is perforated by openings or ostia often segmentally arranged through which the returning blood enters the heart. From the heart arteries proceed, mostly anteriorly and posteriorly, but soon become vague, passing into spaces (sinuses). Especially in the smaller forms there is a lack of definite vessels whereas the larger ones have arteries of some length and a system of sinuses. The blood contains amoeboid cells, similar to vertebrate leucocytes, and a dissolved oxygen-carrying substance which in most Crustacea is a hemocyanin, containing copper instead of iron as the important metal; hence the blood is colorless or bluish. However, some Crustacea are said to have red blood containing dissolved hemoglobin.

The smaller Crustacea lack a definite respiratory system, carrying on gaseous exchange through the general body surface and especially through the foliaceous feet which are often kept in rhythmic motion. The higher Crustacea are provided with gills, feathery or lamellate thin-walled structure borne chiefly on the bases of certain appendages. In the Decapoda, gills also occur on the sides of the thorax and are protected by the carapace which curves down over them to form on each side a branchial chamber. Through such a chamber a respiratory current is usually maintained from behind forwards through rhythmic movements of one of the more anterior appendages.

A pair of excretory organs occurs in the anterior part of the body as a coiled canal leading from a small remnant of the coelom to an exterior pore. They are believed to be remnants of originally segmentally arranged nephridia, one pair to each segment. The surviving pair is that belonging either to the antennary or the first maxillary segment, or, rarely, the pairs for both segments may be present.

The sexes are separate in the majority of Crustacea; hermaphroditism obtains in barnacles and some isopods. The two sexes are generally morphologically distinguishable by differences in the appendages already mentioned, further by

differences in size and shape. Either sex may be the larger and such size differences are often very great. The reproductive system is simple, consisting of a pair of ovaries or testes from which a pair of ducts leads to the external openings, variously located either in the body wall or at the bases of certain appendages. In the higher Crustacea, the male and female pores are always on different appendages. The sperm is often done up in packets or spermatophores for easier transference to females, and females may have special pockets in the exoskeleton for receiving and holding the spermatophores. The eggs are generally carried about by the female fastened by an adhesive substance to her appendages or are held in brood pouches. The eggs usually hatch to a free-swimming larva of which the most primitive type is the nauplius larva (Fig. F). This is a minute creature of oval form with three pairs of leg-like appendages that represent the antennules, antennae, and mandibles and with an unpaired eye. This larva usually passes through more advanced larval types before attaining the adult morphology and among many higher Crustacea the nauplius stage is passed during embryology and a more advanced type of larva emerges from the egg. A number of different larval types and stages occur among the higher Crustacea, many of bizarre appearance. The fresh-water Crustacea usually lack free-swimming larvae and have the adult morphology at hatching.

Parthenogenesis, i.e., development of the eggs without being fertilized by sperm, occurs in the orders Branchiopoda, Ostracoda, and Isopoda, and has been extensively studied in the first named, especially in the genus *Daphnia*. In this and related genera, females may be produced by parthenogenesis for many generations but at times males appear, and fertilized eggs having a heavy shell and capable of withstanding freezing and drying are laid. These invariably hatch into a female. Experiment has shown that the production of males is controlled by external factors, especially number of mothers per unit space.

Classification, Habits and Habitats.—The Crustacea are conveniently divided into two subclasses, the Entomostraca (q.v.) or lower forms and the Malacostraca (q.v.) or higher Crustacea. The Entomostraca are chiefly small or even microscopic forms that show a great variety of body form and appendage type and in general lack definite regionation. The Malacostraca are the larger, more definitely constructed types with 19 segments having the appendage types described above. The Entomostraca comprise the orders Branchiopoda, Ostracoda, Copepoda, Branchiura, and Cirripedia. The Branchiopoda are subdivisible into the suborders Phyllopoda, that includes the fairy shrimps (Fig. G) with elongated jointed bodies and at least 10 pairs of foliaceous feet, and the suborder Cladocera or water fleas such as *Daphnia* (Fig. E) with short, poorly segmented bodies enclosed except the head in a bivalved carapace and with four to six pairs of foliaceous feet. The ostracods or cyprids are completely encased in a bivalved carapace. The copepods exemplified by *Cyclops* in fresh water (Fig. C) and *Calanus* in the sea have an elongate body without carapace terminating in furcal bristles. The Branchiura or fish lice are copepodlike parasites found on fish and other cold-blooded

aquatic vertebrates. The Cirripedia or barnacles are sessile animals enclosed in a carapace that contains calcareous plates; they are of two types: the rock barnacles fastened directly to rocks and the goose barnacles borne on a stalk.

The Malacostraca are divisible into the orders Leptostraca, Anaspidacea, Mysidacea, Cumacea, Tanaidacea, Isopoda, Amphipoda, Euphausiacea, Decapoda, and Stomatopoda. Of these only the Decapoda, comprising the lobsters, crayfish, shrimps, crabs, hermit crabs, the Isopoda, including the sowbugs, and pillbugs, and the Amphipoda, sandhoppers and scuds, are of popular interest.

The Crustacea are among the most common and familiar aquatic animals, found in both fresh and salt waters. They show a wide range of habits and habitats. The Entomostraca are primarily planktonic animals (i.e., swim about in the open waters) and play an important role in aquatic food cycles. Particularly copepods of the *Calanus* type occur in vast numbers in the surface waters of the ocean and furnish food for many other organisms. The fairy shrimps and other phyllopods mostly inhabit temporary fresh-water pools, appearing in very early spring and quickly completing their life cycles with the laying of thick-shelled eggs that can endure drought and freezing. Perhaps the most remarkable phyllopod is the brine shrimp, *Artemia*, that lives only in brine pools in a salinity ranging as high as 30 per cent sodium chloride, or about nine times the salinity of the ocean. Bottom dwelling habits are seen among various types of decapods, many of which live in crevices or dig burrows in shallow water. The spider crabs are distinguished by their extremely long and slender legs and the giant spider crab of Japan, whose legs may be 11 feet long, is the largest of living arthropods. The hermit crabs occupy empty snail shells and show marked body and behavior changes associated with this habit. The barnacles furnish an excellent example of adaptation to sessile life; their nauplius larvae swim about for a time and then settle head down on appropriate objects to which they become permanently fastened. Cave-dwelling habits with degeneration or loss of eyes and pale coloration occur in a number of fresh-water crustaceans, especially isopods. Adaptation to living on land is seen in various crabs in the tropics, known as land crabs, and especially among the isopods, of which the terrestrial members, known as sowbugs, pillbugs, and woodlice, are familiar objects under stones, flower pots, and boards or fallen logs. These terrestrial isopods have a special adaptation for air breathing in the form of a system of tubes similar to the tracheae of insects, occurring on certain abdominal appendages. Commensal habits, i.e., the habit of constant association with some other animal, are of common occurrence among the Crustacea, and various degrees of parasitism are also illustrated among them, with accompanying alterations of structure, often extreme. Many copepods and the related Branchiura lead a parasitic existence on fish and other animals and often show marked reduction of body structure and of appendages. An extreme case of parasitic degeneration is found in the group Rhizocephala, belonging to the order Cirripedia. These forms parasitize crabs and are reduced to a sacciform protrusion on the outside of the crab from which rootlike feeding extensions permeate the host's organs. The cirripede nature of the rhizocephalan parasites can

be recognized only through the embryology in which a typical barnacle nauplius appears.

Crustaceans in modern research.—Present research concerns chiefly plankton studies on Entomostraca, life cycles of crustaceans of economic importance, and hormones in crustaceans. Studies of abundance, distribution, population fluctuations, and so on, of Entomostraca are desirable because of their importance in the food cycle in fresh and marine waters. Knowledge of life cycles is a necessary preliminary to conservation of crustaceans used as food. Much research centers on crustacean hormones since the discovery in 1928 that color changes in certain crustaceans are controlled by hormones produced in the eyestalks, found to contain two glands. The colors of such animals are vested in pigment cells and hormonal control of degree of expansion and contraction of these cells determines the color, which can alter with background, and also often shows a day-and-night rhythm. Hormones are also concerned in molting. See also BARNACLE; CRAB; FISH LICE; HERMIT CRABS; LOBSTER, SHRIMP.

Department of Lower Invertebrates, American Museum of Natural History.

CRUTCHED FRIARS (also called **CROSSED FRIARS**; **FRATRES CRUCIFERI**), an order of mendicant friars of the Middle Ages. They claimed to have been founded in the East by St. Anacletus in the 1st century; but they are known historically only from 1169, when Pope Alexander III prescribed a rule for them similar to that of the Augustinians. Their habit was brown or black, with a cross of red cloth, and they carried wooden staves that had crosses at the top—circumstances which gave them their name. In the 15th century Pope Pius II changed the color of their habit to blue and prescribed a small silver cross for the large wooden one they had carried.

At one time the order is said to have had 208 houses in Italy, headed by the priory of Santa Maria di Morella at Bologna, which was made their chief house by Pope Clement IV (r. 1265–1268). In 1244 this house had sent a contingent to England, where a house was founded in the next year, probably at Colchester or Reigate. In 1249 they formed a house at London, near Tower Hill in a section long called Crutch Friars, and some six or seven other English houses were eventually founded. Later various abuses crept in, and there were only 50 houses or fewer in 1656, when the order was suppressed by Pope Alexander VII.

A similar order of friars, also called **Frates Cruciferi**, existed in the Low Countries and France from the 13th century to the French Revolution. The habit of these friars was black, with a red cross. Other **Frates Cruciferi** existed in Bohemia in the 13th century and still others are said to have lived in Ireland.

CRUVEILHIER, krü'vā'li-ā', Jean, French anatomist: b. Limoges, France, Feb. 9, 1791; d. Jussac, March 6, 1874. He obtained in 1824 the chair of pathological anatomy in Montpellier and in 1826 in Paris. He published an important work *Essai sur l'anatomie pathologique en général* (1816). His other works include *Anatomie Descriptive*, 3 vols. (1833–1838); *Anatomie du système nerveux de l'homme* (1845); and *Traité d'anatomie pathologique générale* (1849–1864).

CRUX or SOUTHERN CROSS, in *astronomy*, a constellation of the southern hemisphere, composed of four stars, one of which is of the first and two of the second magnitude. They form a figure not unlike a cross, especially when seen above the pole, and are the best-known of the southern constellations.

CRUZ, SAN Juan de la. See JOHN OF THE CROSS, SAINT.

CRUZ, krōōs, Juana Inés de la, Mexican poet nun: b. Nepantla, Nov. 12, 1651; d. April 12, 1695. Author of three volumes of poetry, drama, and prose, published by her admirers in Spain, she was undoubtedly the greatest woman Spanish America produced during the colonial period with the exception of St. Rose of Lima. A contemporary of Anne Bradstreet, like the New England poetess, Sor Juana (Sister Jane) was known to the people of her time as the Tenth Muse. She wrote some beautiful sonnets and *liras*, but is chiefly remembered for her *Redondillas*, a poem castigating men for their unfair treatment of women. This has won her the name of the first feminist of Spanish America. In a letter to the bishop of Puebla, *Respuesta a Sor Filotea de la Cruz* (1691), Sor Juana told much about her life and advocated education for women. Born Juana de Asbaje, from early youth she craved an education and at the age of eight begged to be sent to the University of Mexico. She was sent to Mexico City, but wide reading took the place of formal schooling. She was given a post in the viceroy's court. This social success did not satisfy her, however, and she retired to a convent for her devotion to learning, two years before her death she gave up her books and studies. When a plague invaded her convent, she nursed the stricken nuns and died of the contagion. Her works, published in Madrid, include *Inundación castálida* (1689); *Poesias* (1691); *Obras póstumas* (1700).

CRUZ, krōōth, Ramón de la (in full RAMÓN FRANCISCO DE LA CRUZ CANO Y OLMEDILLA), Spanish dramatist: b. Madrid, Spain, March 28, 1731; d. there, March 5, 1794. He produced some 500 pieces in all departments of dramatic composition—classical drama, comedy, farce, *sarsuela* (musical comedy), and a mixture of classical drama, more especially of the French school. He also translated and adapted plays from Italian and French. So prolific was he, so devotedly did he work, and so endless were his literary and dramatic resources, that he has been called the Lope de Vega of the 18th century. He worked for all the theaters of Madrid; and often a week or less sufficed him to write a play or *sarsuela*. This work he kept up constantly for 30 years. Nineteenth century critics were inclined to belittle his work; but modern historians of the theater are finding in his dramas the mirror held up to the Spanish life of the 18th century, and they are beginning to understand what de la Cruz meant when he said of himself: "Truth dictates and I write"; for his works are a vast and rich treasury of information relating to the life and customs of the age in which he lived and which he knew thoroughly. In rescuing Spanish drama from foreign influence and in developing the *sarsuela*, and the *sainete* (one-act farce) and other short and characteristically Spanish plays,

he led the way for the modern renaissance of the Spanish drama.

(Consult Cotarelo y Mori, *Ramón de la Cruz y sus obras* (Madrid 1899).)

CRUZ Y GOYENECHE, krōōs ê gō-yā-nā'chā, Luis de la, Chilean military officer: b. Concepción, Chile, Aug. 25, 1768; d. near Val paraíso, Oct. 14, 1828. He explored the Andes in 1806, discovering several important mountain passes, which are described in a report published in the Angelis collection at Buenos Aires in 1835. He bore a leading part in the revolution against Spain, commanding a regiment and falling into the hands of the enemy, but was liberated in 1817. He next became a political leader of the young republic, serving for a time as acting president of Chile. He was invested by Peru with the dignity of grand marshal. Shortly before his death he was appointed minister of marine.

CRYOLITE, a double fluoride of aluminum and sodium, $3\text{NaF} \cdot \text{AlF}_3$, occurs in commercial quantity and is mined at only one place, Ivigtut, Greenland. This comparatively rare mineral is colorless when pure and crystallizes in the monoclinic system. It has a hardness of 2.5, and a specific gravity of 2.96. The mineral fuses at 950°C . with practically no loss in firing. Cryolite is found in commercially unimportant sources in the St. Peter's Dome district, Colorado; at Miasik, in the Urals; and in Canada. Synthetic cryolite was manufactured in the United States in 1950 by the Aluminum Ore Co. at East St. Louis, Ill., and the Reynolds Metals Co. at Bauxite (Hurricane Creek), Ark. The mine at Ivigtut, Greenland, is owned by the Danish state, and the mining concession is exploited by the Kryolitselskabet Oresund A/D of Copenhagen. The crude ore output is normally divided about equally between the Pennsylvania Salt Manufacturing Co. of Philadelphia, and the Danish company's manufacturing plant in Copenhagen.

The crude ore which contains many impurities is converted into various manufactured products. One product from the processing plant is a white powder containing 99.4 per cent natural cryolite that is used in the aluminum industry, where it acts as the electrolyte in reducing alumina to metal. Synthetic cryolite made from fluorspar is used extensively for the same purpose, but has some disadvantages. A high quality cryolite product is used in the enamel and glass industry. It gives whiteness to enamel and is an opacifier in glass. Small tonnages are used as a binder for some abrasives and also as an insulating material having special dielectric properties. Another product is used as an insecticide.

Imports of natural and artificial cryolite into the United States in 1950 were 15,298 long tons valued at \$978,175, all from Greenland with the exception of 98 tons from Belgium; exports from the United States in the same year were 1,850 long tons, valued at \$404,931.

ALVIN S. COHAN.

CRYPT, krīpt, in architecture, a cell or vault constructed underground. The galleries of the catacombs and the catacombs themselves were known by this name in the early Christian era. The underground tombs of the Christian martyrs were so called where the early Christians met to perform their devotions, for fear of persecution. Hence crypt came to signify a church under-

ground, or the lower story of a church, which may be set apart for monumental purposes, or used as a chapel. It came to occupy the entire space under the choir; and often the part of the church above it was elevated and approached by flights of stairs, in order to give height to the crypt. The crypt is not common in churches built after the Norman period and when found in those of the Gothic period is usually much older than the structure above them. The position of a

Crypt of St. Eutropius at Saintes, France.

crypt is generally beneath the choir, but occasionally, as at Glasgow Cathedral, beneath the transept also. The largest crypt in England is that at Canterbury Cathedral. Crypts rarely occur as a feature of a parish church. The larger crypt at Glasgow Cathedral is entirely above ground and at one time was used by itself as a church. In Germany, these underground chapels are numerous—the ones at Gottingen, and Naumberg are fine examples of architecture. The most remarkable crypt in Italy is that of St. Mark's, Venice,

Decoration of crypt in catacomb of Praetextatus, 3d century.

which is in the shape of a Greek cross. Short columns support low arches on which the floor above rests. Other Italian crypts are at Brescia, Fiesole, Modena, Milan, Pavia, Verona, Florence; and a particularly fine one at Assisi. A good example of Norman crypt is to be seen at the church of the Holy Trinity at Caen, France. In the latter country there are notable crypts at St. Chapelle, Paris, at St. Gervase, Rouen, and the cathedral at Strasbourg. Later churches abolished the necessity for this form of chapel.

CRYPTOBRANCHIDAE, krīp'tō-brān'kī-dē (Gr. "of the family of hidden gills"), a family of aquatic urodele Amphibia (q.v.), represented today in Japan and China and the eastern United

States, but represented by fossils in the Miocene of Europe and the Pliocene of western North America. They appear to be closely related to the Asiatic salamanders of the family Hynobiidae, a family including the most primitive known Urodela. The Hynobiidae and Cryptobranchidae together differ from the salamanders in the external fertilization of the eggs, with the consequent absence in the male of specialized glands for the secretion of a spermatophore, and absence in the female of a sperm-receiving and storing sac. In their skeletons they also differ from other salamanders in the absence of an ethmoid bone, incompleteness of the bony partition between inner ear and brain and freedom of the angular bone. The Cryptobranchidae differ from the Hynobiidae in the absence of a lacrymal bone and in retaining larval characters throughout life.

There are two genera: *Megalobatrachus* (without gill opening in adult) from China and Japan, and *Cryptobranchus* (with one gill opening) from the eastern United States. They are the largest known salamanders, *Megalobatrachus* reaching a length of over five feet, though *Cryptobranchus* does not exceed 27 inches. See HELL-BENDER.

CRYPTO-CALVINISTS, krīp'to kāl'vīn-ists, name given to Melancthon and those who agreed with him in wishing to unite the Lutherans and Calvinists, and especially in his supposed leaning toward the Calvinistic view of the Lord's Supper as shown in the difference between the original and the altered Augsburg Confession (q.v.). The former said "The body and blood of Christ are truly present in the Lord's Supper in the form of bread and wine and are there distributed and received by the communicant; therefore the opposite doctrine is rejected." In the latter the last clause is omitted. Luther did not approve the alteration, but tolerated Melancthon's change of doctrine. Many, however, called him a Crypto-Calvinist. The truth seems to have been that he did not consider that either opinion was a sufficient bar to communion with Christ and therefore thought that both of them ought to be allowed. The controversy was becoming violent before his death, but afterward it broke out with great virulence, and continued with alternate success for 50 years, during which time frequent attempts were made to suppress the Calvinistic opinions by imprisoning their leading advocates and at last, in 1611, by the execution of Chancellor Nicolas Crell. The term has also been applied to the Missouri Lutherans because of their acceptance of the doctrine of unconditional election.

CRYPTOGAMOUS PLANTS or **CRYPTOGAMS** (from Greek *kryptos*, hidden and *gamos*, marriage) are plants bearing reproductive organs other than flowers. They include algae, fungi, lichens, mosses and liverworts, and ferns and fern allies. The latter (ferns and fern allies) are often called *vascular cryptogams*. Plants bearing flowers are known as *phanerogams*. These designations, dating from Linnaeus, have long lost their scientific meaning but are retained as terms of convenience.

CRYPTOGRAPHY. (Gr. *kryptos* hidden and *graphein* to write), the art of the composition and solution of methods of secret communication.

Methods.—The basic methods by which secrecy of communication may be obtained are: (1) *Code*—a secret language; (2) *Cipher*—ordinary language specially written (this may be done in two ways: *substitution cipher*, or the use of a private alphabet; and *transposition cipher*, in which the order of the letters or the words of the message is scrambled according to an agreed system so that it can be restored by the recipient); (3) *Concealment*—by such methods as invisible ink or by disguising the message as something else, such as a sheet of music. These methods may be used singly or in combination (See also CIPHER AND CODE WRITING.)

Characteristics.—A practically useful cryptographic system must possess the following characteristics:

(1) It must not be so complicated or require the use of such apparatus that it cannot be handled by the person required to use it in the circumstances in which he is placed. A system suitable for diplomatic cables would be useless to a soldier in a foxhole.

(2) It must not be so constructed that a single mistake in composition or in transmission makes nonsense of the remainder of the message.

(3) It must not be possible to extract more than one meaning from the message.

Obvious though these points may appear, systems of insoluble cipher (which do exist) generally fall foul of one or more of them. In selecting the system to be used the guiding rule is to choose the simplest which will defy solution until the information contained in it is of negligible value to an unauthorized reader.

Nomenclature.—As with other arts, there are a few technical terms which need explanation, apart from those defined above. The *clear* is the communication to be made. The *message* or *cryptogram* is the communication after it has been written in code or in cipher. A *group* is either a word in code language (which may stand for a complete phrase of the clear) or an arbitrary grouping of cipher letters or symbols for convenience of transmission or of checking. Natural word divisions are avoided in cipher work, as they make the cryptogram easier to break. To *break* a cryptogram is to reconstruct the code or cipher system by which it was written, the process by which it is broken being called *cryptanalysis*. A *null* is a meaningless word or letter. Other terms will be defined as they arise in the text.

Code.—It is probable that code was the earliest cryptographic method. A husband and wife speaking in a language which their children do not understand are using code. This elementary form of code has two major defects: there is no

positive guarantee that others may not understand, and words employed to describe the subjects discussed may not exist in the language used.

For these reasons artificial languages tailored to suit their intended use are normally employed. The earlier examples, such as the "thieves' cant" of the Middle Ages, were of normal construction, but with special words to replace those of ordinary speech; and were learned by heart by their users with no more difficulty than that of learning any other language. Be-bop slang is of this kind. Modern codes, however, are constructed so that one word or group may stand for an entire phrase or sentence. A well-known example is the International Code group SOS, meaning I AM IN DANGER AND NEED IMMEDIATE HELP. Because of this condensed structure and because the groups are not necessarily pronounceable, it is not practicable to learn modern codes by heart, so that code books, dictionaries of the code language, must be used. A portion of one of these books is shown in Fig. 1.

Varieties.—A code in which both the groups and their meanings are arranged in alphabetical or numerical order is called a *one-part code*. A *two-part code* or *random code* has no relation between the order of the groups and that of their plain language equivalents, so that a book listing the meanings in order, with their equivalent groups, is needed for coding, and another, listing the groups in order, with their equivalent meanings, is required for decoding. A one-part code is easier to compose and to handle and is therefore used for commercial codes in which condensation rather than secrecy is the primary objective, but its orderly construction makes it relatively easy to break, so that random codes are preferred for secret work.

It will be noticed that the groups of one of the codes shown in Fig. 1 are constructed of letters and those of the other of numerals. For commercial codes letter groups are practically universal, but for secret work numeral groups are preferred because they lend themselves better to subsequent ciphering (see section on *Ciphered Code*).

Until 1932 commercial code groups were required by international telegraph regulations to be pronounceable words, but modern practice is to use groups of five letters. These are so arranged that the accidental transposition of two letters or a mistake in one letter will produce a meaningless "corrupt group" rather than an incorrect reading. Take for example the group ABAOY of Fig. 1. ABABY, AABOY, and ABAYO are all meaningless, as is any other group differing from ABAOY by a single letter

One-part letter code		Two-part (random) figure code	
ABALC	Abandon(s) (ing)	53827	Abandon(s) (ing)
ABADM	To abandon	47534	To abandon
ABAEN	They will abandon	39682	They will abandon
ABahr	Abandoned	73593	Abandoned
ABAOY	Abandonment	54481	Abandonment
ABARA	Abated	27496	Abated
		01136	Will dispute
		01142	Cancel
		01151	Sail(s) (ing)
		01168	Harbor dues
		01175	Calm
		01184	Fuel

Fig. 1. Types of code book.

or by the transposition of two adjacent letters. Similar safeguards are provided in numeral codes.

A one-part code composed by enumerating words from a dictionary by page and line is called a *dictionary code*. This is easily broken, because in any dictionary of similar size and make-up to that used to form the code the same words will fall in approximately the same positions. If an ordinary book is used, a much more resistant random code is produced, but the difficulty of locating the desired words, when coding, is usually so great that the code is practically useless.

A special type of code is that designed to pass information while preserving the appearance of an innocent message. A telegram reading TELL UNCLE TO COME AT ONCE MOTHER SINKING FAST might pass without comment, even in wartime, but if UNCLE is the code group for ALL SUBMARINES IN AREA, MOTHER means CONVOY OF OVER 50 SHIPS, and SINKING FAST equals SAILING WITHIN 48 HOURS, the telegram acquires a different complexion. The difficulty with this type of code is to detect its presence; once identified, it is seldom hard to break. It may sometimes be detected due to unnatural wording of the message, but more frequently because the sender or the addressee are persons on whom suspicion has fallen for other reasons. For other developments of code see the section *Ciphered Code*.

Solution.—Codes are more frequently compromised by carelessness, betrayal, or capture than by the efforts of the cryptanalyst, but they may be broken by essentially the same method as is used by someone thrown among uncooperative foreigners to learn their language. If a commercial agent dispatches a cargo of potash when, and only when, he receives a message from his principal containing the group EEVAL and receives potash whenever he sends a message containing the same group, it becomes practically certain that EEVAL has some connection with potash.

This method of attacking a code is known as the "probable word" technique. It may be applied also to ciphers and, in the proper hands, is extremely powerful, but its consistently successful application seems to require an intuitive gift possessed by a minority of individuals. The extremely stereotyped wording of most diplomatic and military dispatches is a great help in this method of cryptanalysis.

Cipher.—When literacy was confined to a restricted class, usually of priests, any alphabet would be meaningless to almost everyone other than the intended recipient of the message. As soon as this ceased to be so, variations on the standard alphabet would be introduced to preserve the secrecy of a message, when required, such variant alphabets being ciphers in the normal modern sense of the word.

Transposition Cipher.—The earliest cipher

The clear HIDE AT ONCE A WARRANT IS OUT FOR YOU is here written in a 6 by 5 letter rectangle, filled out with a null P.

	1	2	3	4	5	6
1	H	I	D	E	A	T
2	O	N	C	E	A	W
3	A	R	R	A	N	T
4	I	S	O	U	T	F
5	O	R	Y	O	U	P

The encipherment may be performed by following any "route" through the figure, as:

- (1) Down column 5, up 3, down 1, up 6, down 2, up 4; giving AANTU YORCD HOAIO PFTWT INRSR OUAEE.
- (2) Round an anticlockwise spiral, beginning at line 1 column 3; DIHOA IORYO UPFTW TAE CN RSOUT NAERA.
- (3) Following the diagonals from left to right and downward, beginning at the top right hand corner; TAWEA TDENF ICATP HNRUU OROOA SYIRO.

Any other figure and any agreed route may be used. The figure may also be formed of complete words, one to each small square of the figure, and the words may be route transposed in a similar manner.

Fig. 2. Route transposition cipher.

The letters of each language listed are arranged in order of frequency of appearance. The percentage figure opposite each group of letters represents the approximate number of appearances of each letter of the group in 100 letters of normal text. The classification is fairly reliable for messages of 200 words or over in English or German, 500 for Spanish and French. If "the" is omitted from English text, T and H each drop into the group below.

English	French	Spanish	German
1—E	1—E	1—EA	1—E 17%
2—T	2—ASITN	2—OS	2—NI 8%
3—AONRIS	3—RULO	3—RNID	3—STRAD 6%
4—H	4—D	4—LCTU	4—HUG 4%
5—DLFCMU	5—CMP	5—MP	5—MCLB 3%
6—GYPWB	6—VQGBHJ	6—BGYVQHFZJX	6—OFK 2%
7—VKXJQZ	7—XY	7—KW negligible	7—WVZP 1%
	8—ZKW negligible		8—JQYX negligible

Fig. 3. Letter-frequency tables.

system of which we have a specific description is the *skytale* transposition cipher used by the Spartans about 450 B.C. A narrow belt was wound round a fairly thick rod (Gr. *skytale*) and the clear written on it, so that, when unwound, the belt appeared to be covered with a meaningless jumble of letters, which would then have attracted no more attention than would a woman's head scarf similarly decorated today. The recipient wound the belt round an identical rod to read the clear. This was an excellent system, combining a system of cipher with a method of concealment, but useless once the secret was known, as a suspicious belt needed only to be tried on different sizes of rod to break the message.

Route cipher: In most modern systems the transposition is performed on paper. The clear is written in the form of a rectangle or other geometrical figure and is ciphered by following an agreed route through the figure. One of the simplest forms of route cipher is the *rail fence*. The clear is written in two lines by alternate letters and is copied by following the horizontal lines. The clear HIDE AT ONCE A WARRANT IS OUT FOR YOU is written:

H D A O C A A R N I O T O Y U
I E T N E W R A T S U F R O

and is transcribed as HDAOC AARNI OTOYU IETNE WRATS UFROP. P is a null to complete the last group.

A more resistant cipher is produced by writing the clear in the form of a more or less equal-sided rectangle and following any convenient route to form the cipher message. See Fig. 2.

To break a transposition cipher it is first identified as such by the fact that the frequency of letter occurrence is normal for the language used. Fig. 3 gives letter-frequency tables for English, German, French, and Spanish. The usual method of solution is to reconstitute the original figure, a rectangle in the vast majority of cases. Taking the message of Fig. 2 (2), DIHOA IORYO UPFTW TAE CN RSOUT NAERA, there are 30 letters, which may be factorized as 2 by 3 by 5. The rail fence, or 15 by 2 rectangle, is easily checked and rejected. Of the other possible rectangles 6 letters by 5 and 5 by 6 are the most likely. As the most common route follows the vertical columns in some irregular order, the message is arranged vertically in columns of 5 letters.

D I U T R N
I O P A S A
H R F E O E
O Y T C U R
A O W N T A

Shuffling the columns, in their existing vertical order or reversed, gives no sensible reading from the horizontal lines, so that some other route or some other figure has been used. Other figures giving no better success, the message is re-examined. The high-frequency combinations of low-frequency letters YOU and OUT may well be part of the clear, in which case part of the message has been routed in the same direction as that in which the clear had been written—which leads to the possibility that some other part of the message may be the clear reversed. The examination of this possibility shows the fairly rare but pronounceable HID in the first group. HID.

YOU, OUT are thus probable portions of the horizontal lines of the assumed rectangular figure. HID cannot be extended at all in one direction and in the other gives most unlikely combinations. It is therefore possible that the route started in the middle of a horizontal line and then changed direction. Following the outline of a 6 by 5 letter rectangle gives

H I D
O
A
I
O R Y O U

This picks up with the YOU combination already assumed to be part of a horizontal line; continuation of the spiral thus indicated will reconstitute the original rectangle. This analysis has been given in some detail, for it demonstrates the basic method of solution of a route cipher.

Double transposition cipher: This is a form of route cipher in which the clear is written and is ciphered by the method described in the preceding section; the resulting message is transposed again by using the same or a different route and figure. It is more difficult to solve than a simple transposition cipher, but it will yield eventually to analysis, since there is only a limited number of practicable figures and routes and each, if necessary, can be tried in turn.

Cardan grill: This is a method more akin to the Spartan belt cipher. The words or letters of the clear are written through irregularly spaced holes in a sheet of paper or card (the grill), which is then removed and the message sheet is filled up with nulls. This can be very difficult to break, but the requirements that both sender and receiver must have identical grills and that either the actual piece of paper on which the message is written by the sender or an exact facsimile must be used for the decipherment are often difficult to fulfil. Variants of the Cardan cipher in which, for example, the third word after each comma gives the true clear, are difficult to compose and are rarely hard to break. In any kind of Cardan cipher the message is much longer than the clear—another disadvantage.

The Cardan grill is sometimes used to produce what is in effect a particularly complicated route cipher. Using a grill in which the holes are so spaced that words or letters can be written through the holes, the grill rotated 90° about its center and more of the clear written through without interference with those already written, then rotated 90° again; this continues until after the third rotation the message sheet is covered with evenly spaced words or letters (filled with nulls, if necessary) and a message is produced which is not much, if at all, longer than the clear and which can be taken off in groups for transmission.

Used alone, transposition cipher will rarely do more than delay decipherment. Its chief use is in two-step cipher (discussed later).

Substitution Cipher.—Substitution ciphers are first mentioned by Roman writers of the 1st century A.D. as having been used in the time of Julius Caesar (c.50 B.C.); but, since several alphabets were in use in the ancient world, it may have been used very much earlier, for any message written in one language with the letters appropriate to another, for example Latin written in Greek letters, is a substitution cipher.

Simple substitution: In this cipher each letter of the clear is replaced by some other letter or symbol, any cipher symbol always representing the same letter of the clear. In the early Roman or Julian cipher each letter of the clear is replaced by the one falling an agreed number of places earlier or later in the normal alphabetical order. Thus CAT may be ciphered as ECV by replacing each letter with that two places later.

A commoner method is to write out the alphabet with another in irregular order below it:—

Clear letters A B C D E F G H I J K L M
Cipher letters C H I N R E S T A B D F G

Clear letters N O P Q R S T U V W X Y Z
Cipher letters J K L M O P Q U V W X Y Z

This shows the most usual method of producing a disordered alphabet, by putting down a "key word," omitting repeated letters, if any, then the remaining letters of the alphabet in direct or reversed order.

As the method of breaking a simple substitution cipher is basic to the solution of substitution ciphers in general, a worked example is given.

The message is:

1	2	3	4	5
YOCIL	HROQE	OPCPQ	PCKJS	CLBRN
6	7	8	9	10
OBKQH	TLNRO	RJPJK	TCDDC	SQHPX
11	12	13	14	15
PKPBR	HRVOP	RWLNR	CRJSR	TSNXL
16	17			
PKANY	LBRNA.			

A frequency count, always the first step, gives R—11 appearances, P—8, C—7, N, O, L—6, K—5, H, B, J, Q, S—4, T, Y—3, A, D, X—2, E, I, W—1. Although the frequency tables are unreliable in such a short message, the marked frequency of R justifies the tentative assignment R = E. In groups 3—4 the "pattern" series PCPQPC stands out. In English this almost certainly represents TITUTI or ONOTON. The high frequency of P in the message encourages the selection of TITUTI, which may confidently be expanded to TITUTION. Assignment of these values in the message gives:

1	2	3	4	5
YOCIL	HROQE	OPCPQ	PCKJS	CLBRN
SI	ESU	STITU	TION	I E
6	7	8	9	10
OBKQH	TLNRO	RJPJK	TCDDC	SQHPX
S OU	ES	ENTNO	I I	U T
11	12	13	14	15
PKPBR	HRVOP	RWLNR	CRJSR	TSNXL
TOT E	E T E	E IEN	E	
16	17			
PKANY	LBRNA.			
TO	E			

There are no unlikely combinations, and the analysis may be proceeded with. DD appears once (in group 9); the commonly doubled letters in the English language are EE, OO, FF, LL, SS, TT, MM, PP. Eliminating those already identified leaves IFFI, ILLI, IMMI, IPPI, of

which the last three are practically always followed by NG or, in the case of ILLI, ON. IFFI, on the other hand, generally appears in the word DIFFICULT. IEN-E (in group 14) calls for S = C, which confirms this deduction. ESEN is usually preceded by R, and N = R is confirmed by its association with R = E and by its general frequency. The substitution of these equivalents practically completes the decipherment:

1	2	3	4	5
YOCIL	HROQE	OPCPQ	PCKJS	CLBRN
SI	LESU	STITU	TION	I ER
6	7	8	9	10
OBKQH	TLNRO	RJPJK	TCDDC	SQHPX
S OUL	D RES	ENTNO	DIFFI	CULT
11	12	13	14	15
PKPBR	HRVOP	RWLNR	CRJSR	TSNXL
TOT E	LE ST E	ER	IENCE	CR
16	17			
PKANY	LBRNA.			
TO R	ER			

This solves readily to A SIMPLE SUBSTITUTION CIPHER SHOULD PRESENT NO DIFFICULTY TO THE LEAST EXPERIENCED CRYPTOGRAPHER, with a null to fill the last group. The cipher alphabet has been composed by using the key word YESTERDAY, or "yesterday," omitting repeated letters.

Simple substitution with suppression of frequencies: This is a variant of the simple substitution cipher in which several equivalents are provided for the commoner, or all, letters. An example of the type is that in which A may be represented by any number between 1 and 9, B by any number between 10 and 19, and so on. It is not very much more secure than ordinary simple substitution, as in any reasonably large accumulation of material commonly repeated words or letter combinations will tend to be ciphered by an almost identical series of symbols several times, allowing tables of equivalent symbols to be constructed. The cipher then reverts to a simple substitution.

Syllabic: This is a substitution cipher in which the symbols represent syllables instead of single letters. Its characteristics are intermediate between those of a letter cipher and of a code. A cipher of this type, known as the Great Cipher of Louis XIV, was used by the French government during the late 17th and the early 18th centuries. It was regarded as unbreakable at the time of its introduction, but was solved without too much trouble during the 19th century by essentially the same methods as those used for a letter substitution cipher, with a table of syllabic instead of letter frequencies. As it has all the disadvantages of a code with neither its security nor its condensation, syllabic cipher is little used today.

Polyalphabetic or double substitution cipher: A great improvement in security is obtained by the use of this type of substitution cipher, in which a different cipher alphabet is used to encipher each successive letter of the clear. This not only produces a cryptogram in which all the letters have an approximately equal frequency, but also prevents the cryptanalyst from picking "patterns" and other letter combinations which may give a lead to the recognition of "probable

ABCDEFGHIJKLMNOPQRSTUVWXYZ
 ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZ
 AZYXWVUTSRQPONMLKJIHGFEDCB

Fig. 6. St. Cyr rule. As shown, the rule is constructed for encipherment using the key letter N. The result is identical with that obtained by using the Vigenère table. See Fig. 4.

bets printed round the edge (Fig. 8). The disks may be rotated independently round the center spindle and locked together if desired. The disks are rotated to align the letters of the first section of the clear and any other line of letters read off to form the message, and the process is repeated with the next section of the clear. If the same alphabet is used on each disk, the result is a series of simple substitutions changing every 25 or 26 letters; if each disk carries a different alphabet, the result is practically a Vigenère with a disordered table and a long random key.

Modern ciphering machines are essentially electric typewriters or teleprinters with a "cipher drum" in the internal electric circuit. When a letter key is pressed, the cipher-drum circuits cause some other letter to be printed on the paper. After each letter the drum turns, producing a different mix-up of the circuits when the next key is pressed. The effect, again, is that of a Vigenère with a disordered table and a long random key. The message is deciphered by typing

Fig. 7. Cipher disk. This device is a variant of the St Cyr rule (Fig. 6), in which the fixed disk replaces the stock and the movable disk replaces the slide. It is shown set up for ciphering with the key letter N.

it on a similar machine which reverses the action of the cipher drum and prints the clear. Where the necessary power is available and their weight and bulk can be accepted, as in naval and diplomatic service, these machines are very useful and are both faster and more accurate than conventional ciphering methods. A disadvantage for some purposes is that it is not easy to destroy a cipher drum, which contains the key to the cipher, sufficiently to prevent its circuits from being analyzed.

Machines used in cryptanalysis are mostly Hollerith type tabulating machines which, once set up, can analyze a message for repeated letter combinations, count frequencies, try out "probable words," and perform similar mechanical processes faster and more accurately than is possible with pencil and paper.

Concealment.—This is the art of concealing the existence of a communication. Its chief use is in espionage.

"Hiding" Methods.—These are typified by

the device of sticking the stamp over a short message written on the outside of an envelope. A method of this kind, used by the Germans during World War II, employed a technique that enabled the photographic negative of a sheet of typescript to be reduced in size to such an extent that it could be stuck over the period dot in a typewritten letter. The recipient would examine each dot under a microscope, scrape off the speck of gelatin, and enlarge it to produce a legible print. This technical triumph was made ineffective by a United States intelligence agent who picked up a hint of the nature of the method before it was ever used in practice, so that postal censorship detected the micro-dot negatives as soon as they appeared.

Invisible Inks.—These are liquids, normally colorless, which become colored and therefore visible on white paper when treated in some manner. Letters written with many fruit and vegetable juices, milk, alum solution, saliva, and several other liquids, will darken and become

Fig. 8. Bazeries cylinder. This illustration is diagrammatic and shows the principle only. 25 or 26 disks are normally provided. The disks are rotated until the letters of the clear are lined up (COME HERE in the figure) and then locked. Any other line of letters (as YLKIFIZI) may be chosen as the cipher message for transmission.

visible on exposure to heat. Heat-developed inks such as these have been used for over 2,000 years. Inks made legible by other means than heat exist, some, such as quinine solution, fluoresce under ultraviolet light, starch solution turns blue on exposure to iodine vapor, cobalt nitrate is developed by brushing a weak oxalic acid solution over it, and a wide range of other chemical reactions may be employed. Invisible ink is generally used to write messages over some innocent cover, such as a harmless letter or the page of a book or periodical. A soft pen or very fine brush must be used to avoid scratching the surface of the paper, which must not be too highly glazed—otherwise it will be discolored where it has been wetted by the ink. It is in any case extremely difficult to avoid making some visible mark on the paper whatever the ink and method of writing employed. Successive exposure of a suspected paper to heat, iodine vapor, and ultraviolet light will expose all the commonly used inks.

Methods of Disguise.—This technique of concealment leaves the message visible, but under such a form that it is not readily recognisable as a communication. Codes designed so that the message appears to have an innocent surface meaning have been discussed earlier, and a system of cipher invented by Johannes Trithemius exists which is designed in a similar manner. This cipher is a simple substitution with suppression of frequencies in which each letter of the clear may be represented by any one of a list of words, a sufficient choice being available for each letter that a reasonable connected surface narrative can be created. In practice this cipher is so cumbersome as to be almost useless.

There are also those ciphers, such as the Spartan transposition written on a belt, which do not look like messages at all. One such, greatly loved by fiction writers, is the cipher in which a note of music (written, played, or even sung) represents a letter of the alphabet. Quite apart from the difficulties of using such a cipher "by ear," it is practically impossible to make a playable melody from the letters of any but a specially selected clear. More feasible is the use of a numeral cipher written into the form of a calculation, with the answers regarded as nulls.

Most concealed ciphers are of the *bilateral* type, in which the letters are represented by a combination of two symbols, as in the Morse code. Any two symbols may be used, such as mixed fonts of type, alternating colors in the lettering of a poster, or whatever apparently innocent combination that ingenuity may devise. A very subtle application of the bilateral cipher, used successfully by a group of anarchists plotting the assassination of the Czar Alexander II, consisted of a fairly difficult double transposition cipher covering a relatively innocuous clear, handwritten in 5-letter groups. The real message was written in a bilateral cipher, of which one symbol was a group of the cover message in which the pen had been lifted between two letters and the other a group written without lifting the pen. The secret police were so intent on the analysis of the transposition cipher message that they never noticed the presence of the bilateral cipher.

If successful, concealment methods are superior to any other, since no higher degree of security can be imagined than complete ignorance on the part of all except the intended recipient that any message exists to be read; but the secret may always be betrayed by espionage, carelessness, or chance, and, once known to anyone not completely trustworthy, no concealment method can be regarded as safe.

History.—From the nature of the subject the history of cryptography is not well documented. Considerations of military and political security have usually ensured that the professional cryptographer does not publish anything not already common knowledge, so that more than in any other art the major contributions to the literature of the subject have come from amateurs.

There are a few references to ciphers in the works of late classical writers such as Plutarch and Suetonius (both fl. 100 A.D.), but for the next thousand years cryptography appears to have been practically a lost art. In view of the general illiteracy of the period this is hardly surprising. The English friar Roger Bacon (1214?–1294) described several cipher systems of a fairly elementary nature, but, as in the case of several other writers on cryptography, his actual knowl-

edge of the subject seems to have been greater than might be assumed from his published work, because a complete book attributed to his authorship exists, written in a cipher which never has been broken. It appears to be a multistep cipher, so complicated that it is possible that it is in effect a difficult form of double substitution with transposition. It may also be a ciphered code or even an elaborate joke.

A hundred years after Bacon's death cryptography had become well enough established to justify the employment of professional cryptographers by European governments. A copy still exists of a manual (*Liber Ziferarum*) written by Gabriele di Lavinde, chief cryptographer to the papal curia about 1380. This gives instructions for the breaking of simple substitution ciphers that show that the cryptanalysts of the period could handle them as readily as those of today.

A later professional handbook, *Regulae ad Extrahendum Litteras Ziferatas sine Exemplo*, written about 1475 by Cicco Simonetta (1410–1480), cryptographer of the duchy of Milan, recommends the use of code ciphered by simple substitution with suppression of frequencies, which argues that a very high level of skill in cryptanalysis had been attained by this time.

The year 1518 saw the publication of the first reasonably comprehensive book on cryptography written for general publication. This was the *Polygraphia* of the German abbot Johannes Trithemius (1462–1516), which describes both substitution and transposition cipher systems, including the above-described Trithemius substitution cipher, and suggests methods of solution.

The first description of a double substitution cipher is found in the *De Furtivis Litterarum Notis* of the Neapolitan mathematician Giovanni Battista della Porta (1535–1615), published in 1563; but Porta's cipher was never adopted by professional cryptographers and was soon largely forgotten. The same fate attended the improved system advanced by the French diplomat Blaise de Vigenère (1523–1596) in his *Traité des Chiffres* (1586), which lay neglected for nearly a century after its publication.

Francis Bacon (1561–1626), like his earlier namesake Roger Bacon, included descriptions of cipher systems among his scientific and philosophical writings and appears to have been the inventor of bilateral cipher.

In 1627 Antoine de Rossignol was appointed head of the cryptographic department, or *Chambre Noire*, of the French government, a position which he held until his death in 1678. Rossignol is one of the great figures of cryptographic history, both as a very talented cryptanalyst and as the author of the already mentioned Great Cipher of Louis XIV. It is a little difficult to understand why Rossignol did not adopt the less cumbersome double substitution cipher, but it is possible that he distrusted the orderly formation of the Vigenère and it may be that he had anticipated the Kasiski method of solution. The Great Cipher was carefully devised to be quite unsystematic in its formation and existed in a number of forms, so that the breaking of the cipher used by one diplomat or general would not compromise messages from any other source.

Double substitution cipher was used to some extent in the German states during the late 17th century, but in general codes of a rather crude type were employed throughout northern Europe,

while the Mediterranean powers other than France continued to favor simple substitution with suppression of frequencies.

During the 18th century the practice of cryptography regressed steadily. In the American Revolution some attempt was made on the colonial side to employ double substitution cipher, but this was never seriously adopted. The British at this time favored a system of word transposition, while the French reverted to the use of straight simple substitution.

The invention of the semaphore telegraph (1792) and the introduction of flag signals for naval use sparked the development of the modern type of code, in which a single group may represent a complete phrase, and the commercial introduction of the electric telegraph (1844) gave it the final impetus.

Modern.—The next period of cryptographic development began about 1820. An article by William Blair (1766–1822) in the 1819 edition of *Rees's Cyclopaedia* gave methods of solution for various kinds of simple substitution cipher and described double substitution ciphers without being able to offer any very satisfactory method of attack. This article aroused considerable public interest in cryptography, and may have been responsible for turning the attention of Rear Admiral Sir Francis Beaufort (1774–1857), who devised the Beaufort cipher, to the subject.

In a series of articles published in *Graham's Magazine* during the early 1840's Edgar Allan Poe (1809–1849), a very talented cryptanalyst, demonstrated that no variant of the simple substitution cipher was capable of resisting solution for very long in a message of reasonable length.

By 1850 double substitution or route transposition ciphers were used in all serious work. The British scientist Sir Charles Wheatstone (1802–1875) devised the Playfair cipher about 1860, but this remained unused until its introduction into the British Army 50 years later.

In the United States the Civil War found the South using the Vigenère cipher and the North a simple word transposition. The Northern cryptographers did a very good job of breaking the Southern ciphers. Since the Kasiski analysis was not known to them, they relied on "probable word" methods, helped by the cryptographically slovenly Southern habit of preserving the word divisions of the clear. The South displayed in general an almost incredible cryptographic ineptitude. Even though they had masses of material on which to work, they never succeeded in reading a Northern cryptogram except when they captured a cipher book, and, whenever this happened, a relatively minor change in the routing of the transposition was enough to re-establish the security of the cipher.

In 1863 a Major F. W. Kasiski of the Prussian General Staff published the Kasiski method of analysis of double substitution cipher, which was followed 20 years later by the Kerckhoffs technique for extraction of the key word, and a few years after that by the method of mathematical coordinates. These methods are all fairly reliable when properly handled, but are inclined to be slow and arduous when applied to complex ciphers.

In 1899 Commandant Étienne Bazeries, then head of the French cryptographic bureau, was faced with a series of Vigenère cryptograms composed with a disordered table and a long key, a poem by Alfred de Musset. These cryptograms,

which emanated from a royalist group plotting a rising against the republic, were broken in a remarkably short time by the brilliant application of "probable word" methods, which were fully described at the trial of the conspirators. This demonstration of the power of the "probable word" technique has affected all cryptographic practice since that time, though it is probable that the increased availability of machines which remove much of the drudgery of the more rigid methods of analysis will increase their popularity for the solution of systematically constructed ciphers. For codes and unsystematic ciphers, however, the "probable word" remains the most consistently profitable method of attack.

World War I saw the general adoption of the Playfair cipher, introduced by the British, for military communications. Codes were regularly betrayed by espionage and by capture; and the breaking of new German ciphers was aided by their habit of broadcasting standard test messages in each cipher as it was introduced into service. Both sides regularly compromised new codes and ciphers by sending messages in the new form to isolated ships or units and then by having to repeat them in the old code or cipher because the addressee had not yet received the new one. As a result of these experiences ciphered codes have replaced straight codes for most applications where interception is probable, the cipher step being changed at regular intervals. The introduction of satisfactory types of electric ciphering machine has led to an increase in the popularity of the irregular double substitution cipher.

Bibliography.—Not very much on cryptography that is of interest to the serious student has been published recently in English and most of this is reported out of print, though the larger public libraries usually have a few works published since World War I. More serious literature on the subject exists in French than in any other language.

PAUL D. HOBSON,
Lieutenant (E), Rtd., Royal Navy.

CRYPTOMERIA, krip-tō-mē'rī-à, a genus of tall (120 to 150 feet), hardy, evergreen, coniferous trees belonging to the Taxodium family (Taxodiaceae). Generally regarded as monotypic, the Japan cedar or "sugi" (*C. japonica*) is found growing wild in southeastern China and throughout Japan as far north as Hondo. The Chinese populations of this species are sometimes treated as a separate species. For centuries this picturesque species has been cultivated, especially in temple gardens of China and Japan and elsewhere, in a variety of horticultural forms since the beginning of the 19th century. The awl-shaped leaves, projecting from all sides of the twig, are bright green in spring and summer, and bronzy crimson in winter. The trees are monoecious. The cone scales, bearing a pair of erect seeds, are imbricate and spread at the tip.

CRYPTURI, *krip-tū'ri* (Gr. "hidden tail," because the tiny tail feathers are concealed by the surrounding feathers), an order of birds, often called Tinamiformes. In general appearance resembling quail or guinea fowl, the tinamous possess many anatomical peculiarities and are perhaps closest to the South American ostrich or rhea. Unlike the latter, however, they have a keel on the sternum and are capable of rapid, if briefly sustained, flight. The approximately 40 species of tinamous inhabit South America and North America north into Mexico; they are all placed in the single family Tinamidae. See TINAMOU.

CRYSTAL, village, Minnesota, in Hennepin County, a northwestern suburb of Minneapolis. Pop. (1950) 5,713.

CRYSTAL CITY, city, Missouri, in Jefferson County, 30 miles south of St. Louis, on the Mississippi River. It has a large plate-glass factory, and nearby are silica pits. Incorporated in 1911. Pop. (1950) 3,499.

CRYSTAL CITY, city, Texas, seat of Zavala County, in the southern section of the state. Crystal City is 95 miles southwest of San Antonio and 35 miles south of Uvalde. It is the shipping center of an irrigated area that grows winter vegetables, and is served by the Missouri Pacific Railroad. Canning is the principal industry. Pop. (1950) 7,198.

CRYSTAL FALLS, city, Michigan, and seat of Iron County, alt. 1,344 feet, near the Wisconsin line, 25 miles north of Milwaukee, on the Chicago and Northwestern and Chicago, Milwaukee, Saint Paul and Pacific railroads. It is a summer resort. Lumbering and iron mining are the chief industries. Under the charter of 1918 government is vested in a commission and city manager. Pop. (1950) 2,316.

CRYSTAL LAKE, city, Illinois, 45 miles northwest of Chicago; on the Chicago and Northwestern Railroad. Situated on the little Crystal Lake, so named by Beman Crandall who first settled on its banks in 1836, the city is a residential community. The adjoining communities of Crystal Lake and Nunda were incorporated as villages in 1874. They united in 1914, incorporating as the city of Crystal Lake. Government is by mayor and council. Pop. (1950) 4,826.

CRYSTAL PALACE, a building at Sydenham, England, about seven miles from London. The material in this building was at one time used in the Crystal Palace erected for the World's Fair which was held at Hyde Park, and was formally opened by Queen Victoria, Feb. 25, 1851. The original building was designed by Sir Joseph Paxton; the materials composing it were glass, iron, and wood. It cost £1,450,000, and every department of art and science was represented. Its area was nearly 21 acres. In 1854, when the building was about to be demolished, a company formed to purchase it tore down the original and removed the material to Sydenham in Kent. The new edifice was patterned after the World's Fair building. The grounds around the Crystal Palace were in area about 200 acres, and beautifully laid out. This palace was opened by Queen Victoria, June 10, 1854. It was de-

stroyed by fire in 1936. The name of Crystal Palace was also given to a large building erected as part of the New York World's Fair of 1853. The site was on Sixth Avenue, between 40th and 42d streets. In 1856 it was destroyed by fire. The locality is now Bryant Park.

CRYSTAL SPRINGS, town, Mississippi, in Copiah County, in the southwestern part of the state. Crystal Springs is situated 23 miles southwest of Jackson, at an altitude of 465 feet. It is a tomato-shipping center served by the Illinois Central Railroad, and manufactures boxes and clothing. Pop. (1950) 3,676.

CRYSTALLINE. See CRYSTALLOGRAPHY—*Crystal Structure*.

CRYSTALLOGRAPHY, the science of crystallization, treated in this article under the following sectional headings:

1. Crystal Morphology
2. Crystal Optics
3. Crystal Physics
4. Crystal Structure

Other aspects of crystallography receive separate treatment under such headings as CHEMICAL CRYSTALLOGRAPHY; CRYSTALS, SYNTHETIC; and MINERALOGY.

1. CRYSTAL MORPHOLOGY. The definition of a crystal rests on the concept of the lattice. A lattice *abc* is an assemblage of points, called nodes, which are the end-points of the vectors

$$L_{uvw} = u\mathbf{a} + v\mathbf{b} + w\mathbf{c}, \quad (1)$$

where the unit vectors *a*, *b*, *c* are not coplanar and *u*, *v*, *w* are all the integers (positive, negative, or zero). It is not a physical concept, but a purely mathematical one—a geometrical way of representing triperiodicity, or repetition by translations in three dimensions.

A crystal is a homogeneous portion of crystalline matter, that is, matter whose intimate architecture is triperiodic (see 4. *Crystal Structure*). This kind of homogeneity is called periodic homogeneity (as opposed to the statistical homogeneity of glass, for instance). It exists only on the scale of direct observations with the naked eye or with the microscope; it disappears on the atomic scale. A crystal need not be bounded by faces; some crystals are (they are called enehedral) and those assume polyhedral shapes. The triperiodicity of a crystal is expressed by the crystal lattice. The period is a parallelepiped called the cell. A net is a two-dimensional lattice, whose period is a parallelogram called the mesh. A row is a one-dimensional lattice whose period, the spacing between two successive nodes, is the parameter or the translation of the row. The periodicity of a wall-paper is expressed by a net; that of its frieze by a row. A space lattice may be visualized as a family of equidistant nets or as a sheaf of parallel rows, the nets or the rows lying in any one of many possible directions.

The co-ordinate axes *Ox*, *Oy*, *Oz* (also called crystallographic axes) are taken along the rows *a*, *b*, *c*, from the origin node *O*. A row line *ON* that joins the origin node *O* to the node *N* with co-ordinates *ua*, *vb*, *wc* is designated by the symbol [*uvw*]. The trimetric co-ordinates *u*, *v*, *w* of the node *N* are, of course, integers; they are called the indices of the row line *ON*. A net

plane can be defined by its intercepts ea , fb , gc on the co-ordinate axes. The integers e , f , g are called the Weiss coefficients (1809). To designate the direction of any plane parallel to the net plane, only the ratios of the intercepts are needed. We have

$$ea : fb : gc = \frac{a}{fg} : \frac{b}{ge} : \frac{c}{ef} = \frac{a}{h} : \frac{b}{k} : \frac{c}{l}.$$

Because e , f , g are integers, h , k , l are also integers. If they are not co-prime, let n be their common factor, so that

$$h = nh', \quad k = nk', \quad l = nl'.$$

First used by Whewell and even by Weiss, but popularized by Miller (1839), the co-prime integers h' , k' , l' are universally known as the "Miller indices" of the net plane. The family of equidistant net planes ($h'k'l'$) divides the unit vectors into equal parts, namely a into h' parts, b into k' parts, and c into l' parts. Let $d(h'k'l')$ be the interplanar distance, that is, the perpendicular distance between any two successive net planes in the family; let $A(h'k'l')$ be the mesh area of the net ($h'k'l'$); then

$$A(h'k'l') \cdot d(h'k'l') = V,$$

where V is the volume of the cell.

Symmetry.—An operation that transforms a figure F into a figure F' is called an operation of the first or of the second kind according as F' is congruent (superposable) or enantiomorphous (mirror-image) to F . If F' coincides with F , the operation is called a symmetry operation; it is said to bring F to self-coincidence. For example any lattice translation L_{uvw} is an operation of the first kind and is a symmetry operation of the lattice. An inversion through the center of gravity of a geometrical cube is an operation of symmetry of the cube; the inversion is an operation of the second kind. The collection of symmetry operations of a crystal polyhedron is a finite group; the collection of symmetry operations of a crystal structure is an infinite group. In these sentences the word group (Galois, 1832) is used in its mathematical sense, for—in accordance with the definition of a group—the following conditions are fulfilled: (1) among the operations of the collection, there always exists a unit operation, also called identical operation or identity (it consists in leaving the figure untouched); (2) the product of any two symmetry operations of the collection (or the square of any one) is itself a symmetry operation of the collection (the symbolic multiplication consists in applying the two operations in succession); (3) the symbolic multiplication is associative; (4) to every operation x there exists an inverse operation x^{-1} (such that the product of the two is the identical operation: $xx^{-1} = x^{-1}x = x^0 = 1$). For example, if x is a counterclockwise 90° rotation about a certain axis, its inverse x^{-1} is a clockwise 90° rotation or a counterclockwise 270° rotation about the same axis.

Point Groups.—To study the symmetry of a crystal polyhedron, it is convenient to replace it by the sheaf of its face normals, that is, the sheaf of perpendiculars dropped onto the faces from any point inside the crystal. This scheme emphasizes the direction of a face in contradistinction to its position in space. Bringing a crystal to self-coincidence means bringing its sheaf of face normals to self-coincidence. One

point, the apex of the sheaf, remains fixed (hence the name point group).

The two kinds of symmetry operations are (1) a rotation about an axis through an angle $360^\circ/n$; (2) a rotation combined with an inversion through a point lying on the axis (the fixed point); this is called a rotatory-inversion. In either operation the value of n must be one of the integers 1, 2, 3, 4, and 6. Proof of this statement follows from the properties of a lattice. One may get an intuitive idea of the proof from the fact that a floor cannot be paved with pentagons, nor with any polygons having more than six sides (regular polygons, that is).

A symmetry operation and all its powers constitute a group called a symmetry element. For example, let x designate a 120° rotation about a certain axis. The operations: $x = 120^\circ$ rotation, $x^2 = 240^\circ$ rotation, $x^3 = 360^\circ$ rotation $= x^0 = 1$, constitute a symmetry element, which is called a rotation axis of 3-fold symmetry or a rotation axis of order 3, and is symbolized by the figure 3. Any rotation axis is likewise designated by the integer n that expresses the smallest rotation angle, $360^\circ/n$. The powers of a rotatory-inversion constitute an inversion axis of symmetry, it is designated by the symbol \bar{n} , where n has the same values as above. For example, let y designate a 90° rotatory-inversion. The 4-axis comprises the following operations: $y = 90^\circ$ rotatory inversion, $y^2 = 180^\circ$ rotation, $y^3 = 270^\circ$ rotatory-inversion, $y^4 = 360^\circ$ rotation $= y^0 = 1$. It is seen that a 4-axis includes a 2-axis as a subgroup. Because a 360° rotatory-inversion is nothing more than an inversion in a point, the group 1 is called a center of symmetry (neither 1 nor $\bar{1}$ is defined in direction). Because a 180° rotatory inversion is equivalent to a reflection in a plane perpendicular to the axis ($\bar{2} = m$), the symbol 2 is always replaced by m , and the symmetry element is called a mirror (plane of symmetry), in the Hermann-Mauguin symbolism (1930). The 3-axis expresses the co-existence of a 3-axis and a center ($3 \times \bar{1} = \bar{3}$). The 6-axis would likewise be produced by combining a 3-axis with a mirror perpendicular to it ($3 \times \bar{2} = \bar{6}$); it could therefore be symbolized $\frac{3}{m}$ instead of $\bar{6}$

($3 \times \frac{1}{m} = \frac{3}{m}$), but the symbol $\bar{6}$ is preferred for the sake of mathematical elegance (see Table 1).

The 4-axis is indispensable and irreducible.

The problem of finding all the possible groups of symmetry operations is simplified from the fact that an operation is always accompanied by all its powers so that, instead of combining symmetry operations in all possible manners, it suffices to combine symmetry elements. The solution to this problem was first given by Hessel (1830), but it fell into oblivion until Schoenflies (1891) drew attention to it. Meanwhile independent derivations were proposed (Bravais, 1848; Gadolin, 1864). The 32 point groups are presented in Table 1. The symmetry symbols (under heading "Point Groups") comprise one, two, or three columns. Each column describes the kind of symmetry pertaining to a given direction and all directions similar to it (or equivalent, or of the same kind). A singular direction is a direction different from all others. In the orthorhombic system, there are three singular

CRYSTAL SYSTEMS		Point Groups	Lattice Modes, Lattice Symmetries and Choice of Co-ordinate Axes			Shape of Cell*
Trimetric Systems (Optically Biaxial)	TRI-CLINIC	1 $\bar{1}$	Triclinic-P; $\bar{1}$. Co-ordinate axes parallel to shortest three lattice translations that make all interaxial angles nonacute ($c < a < b$).			$a \neq b \neq c$ $\alpha \neq \beta \neq \gamma \neq 90^\circ$
	MONO-CLINIC	m 2 $\frac{2}{m}$	Monoclinic P or (C, A, or I); $2/m$. Symmetry direction taken as b . Shortest two translations normal to b taken as c and a ($c < a$, β obtuse).			$a \neq b \neq c$ $\gamma = \alpha = 90^\circ, \beta \neq 90^\circ$
	ORTHO-RHOMBIC	$\begin{Bmatrix} 2 & m & m \\ m & 2 & m \\ m & m & 2 \end{Bmatrix}$ 2 2 2 $\frac{2}{m} \frac{2}{m} \frac{2}{m}$	Orthorhombic P, (C, A, or B), I, or F; $2/m 2/m 2/m$. Three symmetry directions taken as a, b, c , respectively ($c < a < b$).			$a \neq b \neq c$ $\alpha = \beta = \gamma = 90^\circ$
Dimetric Systems (Optically Uniaxial)	TETRAGONAL	$\bar{4}$ 4 $\frac{4}{m}$ $\begin{Bmatrix} \bar{4} & 2 & m \\ \bar{4} & m & 2 \end{Bmatrix}$ 4 m m 4 2 2 $\frac{4}{m} \frac{2}{m} \frac{2}{m}$	Tetragonal P (=C) or I(=F); $4/m 2/m 2/m$. First symmetry direction taken as c . Second symmetry direction (shortest translations normal to c) taken as a and b .			$a = b \neq c$ $\alpha = \beta = \gamma = 90^\circ$
	HEXAGONAL s.v.	3 $\bar{3}$ $\begin{Bmatrix} 3 & m & 1 \\ 3 & 1 & m \end{Bmatrix}$ $\begin{Bmatrix} 3 & 2 & 1 \\ 3 & 1 & 2 \end{Bmatrix}$ $\begin{Bmatrix} \bar{3} & 2 & 1 \\ \bar{3} & m & 1 \end{Bmatrix}$ $\begin{Bmatrix} \bar{3} & 1 & 2 \\ \bar{3} & m & 2 \end{Bmatrix}$ $\begin{Bmatrix} \bar{6} & 2 & m \\ \bar{6} & m & 2 \end{Bmatrix}$ 6 m m 6 2 2 6 2 2 $\frac{6}{m} \frac{2}{m} \frac{2}{m}$	Hexagonal-P (formerly C); $6/m 2/m 2/m$. First symmetry direction taken as c . Second symmetry direction (shortest translations normal to c) taken as a and b .	3 $\bar{3}$ 3 m 3 2 $\bar{3} \frac{2}{m}$	Hexagonal-R (= rhombohedral-P)†; $\bar{3} 2/m 1$. Axes as in Hexagonal-P.	$a = b \neq c$ $\alpha = \beta = 90^\circ$ $\gamma = 120^\circ$
Isometric System (Optically Isotropic)	CUBIC	2 3 $\frac{2}{m} \frac{3}{m}$ $\begin{Bmatrix} \bar{4} & 3 & m \\ \bar{4} & 3 & 2 \\ \bar{4} & 3 & 2 \end{Bmatrix}$ $\frac{2}{m} \frac{3}{m} \frac{2}{m}$	Cubic P, I, or F; $4/m \bar{3} 2/m$. First symmetry direction taken as a, b , and c (cube edges).			$a = b = c$ $\alpha = \beta = \gamma = 90^\circ$

* The sign \neq stands for "not necessarily equal to."† The shape of the primitive rhombohedral cell is given by $a = b = c$, $\alpha = \beta = \gamma \neq 90^\circ$.

Table 1

symmetry directions. In the dimetric systems, the first symmetry direction is singular; the number in the first column indicates how many symmetry directions in all are expressed by the last two columns. For example, 6 2 2 means: one 6-axis and six 2-axes in all, three of one kind, three of another. In the cubic system, the first column refers to the three equivalent directions perpendicular to the cube faces, the second column refers to the four body diagonals, the third column to the six directions that are parallel to the face diagonals.

Although a lattice is an infinite figure, it possesses point-group symmetry. Indeed, if anywhere in a lattice there exists a symmetry axis, the line passed through any node parallel to this axis is itself (or includes) a symmetry axis of the same order. The same holds true of mirrors. From the very definition of the lattice, moreover, a node is a center of symmetry. It follows that all symmetry elements can be made to pass through a node, which thus becomes the fixed point of a point group. To be a lattice symmetry, however, a point group must fulfill two conditions: (1) it must have a center; (2) if it has an n -axis, with n greater than 2, it must also have n 2-axes perpendicular to the n -axis. On this basis 7 of the 32 point groups are possible lattice symmetries. The symmetry is reflected in the shape of the cell, as expressed by the relative sizes of the edges a , b , c and the values of the interaxial angles $\alpha = \angle Oyz$, $\beta = \angle zOx$, $\gamma = \angle xOy$. Some edges must be equal and some angles must have special values (90° or 120°) on account of symmetry; these requirements are rigorous and hold at all temperatures. Fortuitous equality of two cell edges or angles accidentally equal to 90° can also occur within the limits of experimental accuracy, but not at all temperatures. The problem of finding the various lattices that possess a given point-group symmetry—the lattice modes of this lattice symmetry—was solved by Bravais (1849). He found 14 lattices in all (instead of Frankenheim's 15 announced in 1842), unequally distributed among the 7 lattice symmetries (Table 1). For each lattice symmetry the lattice may be primitive (P), that is, the cell defined by the vectors \mathbf{a} , \mathbf{b} , \mathbf{c} is as small a cell as can be chosen. It contains only one node (eight corners, shared by neighboring cells, count for one-eighth each). In a given lattice all primitive cells have the same volume regardless of their shapes. In some cases the lattice is centered, that is, the cell \mathbf{a} , \mathbf{b} , \mathbf{c} is a multiple cell, containing more than one node. It may be one-face-centered (either A-, B-, or C-centered, according as the front, the side, or the base of the cell carries the extra node) in which case the cell is a double cell—2 nodes per cell; body-centered (I), also with a double cell; all-face-centered (F), with a quadruple cell; rhombohedral (R), in which case a hexagonal cell, namely a vertical prism with 120° -rhombohedral base, carries two extra nodes with trimetric co-ordinates ($2/3$, $1/3$, $1/3$) and ($1/3$, $2/3$, $2/3$). Rhombohedral "centering" of a hexagonal cell reduces the lattice symmetry from $6/m\ 2/m\ 2/m$ to $\bar{3}\ 2/m$.

The lattice symmetry forms a satisfactory basis for a classification into 7 crystal systems. Many authors, however, prefer 6 crystal systems. In this scheme (Table 1) a single hexagonal system *sensu vasto* includes any crystal whose lattice is either hexagonal-P or hexagonal-R.

External Form.—The laws of observation of

the early crystallographers can be expressed most simply in terms of the lattice: (1) Faces are parallel to net planes and edges to row lines. This is the law of Constancy of Angles, first noted for quartz crystals by Steno (1669), extended to various salts by Guglielmini (1688), and stated in its full generality by Romé de l'Isle (1772). (2) Faces are parallel to families of nets with large interplanar distances. This is the law of Rationality, which was discovered by Haüy in 1784. (It can also be expressed as follows: faces have small Miller indices.) (3) The larger the interplanar distance $d(h'k'l')$ is, the more frequently the face $(h'k'l')$ occurs on crystals of a given species. This is the law of Bravais (1849), a refinement of the law of Haüy, true to a first approximation. (4) The frequency of a face is better measured by $d(hkl)$, where h , k , l are the smallest indices (non co-prime if need be) that obey the space-group criteria (see below). This is a generalization of the law of Bravais (Donnay and Harker, 1937), an improved approximation still falling short of giving a physical explanation of crystal morphology. Recent work in this direction points to bonding, a crystal-structure concept, as having a controlling influence (Hartman and Perdok, 1953).

Determination of Cell Dimensions.—X-ray diffraction methods (see 4. *Crystal Structure*) yield absolute dimensions. From morphology only interaxial angles and ratios of cell edges can be obtained. The experimental data are angles: either interfacial angles, measured by means of a one-circle goniometer (Carangeot, 1780), or the co-ordinate angles of the faces, measured on a two-circle goniometer. The interfacial angle is the angle between the face normals, directly obtainable (to a few minutes of arc) on the reflecting goniometer (Wollaston, 1809). The co-ordinate angles are the longitude and the colatitude of the face pole, the point where the face normal intersects a sphere (sphere of projection) drawn around the crystal. Angles between edges or between the projections of edges can also be obtained, with less accuracy (0.5° to 1°) from microscope goniometry.

The co-ordinate axes must be taken parallel to rows. Because symmetry directions are parallel to rows, they can be used as co-ordinate axes (see Table 1). A face intersecting all three axes is chosen as unit face (111). It determines, on the axes, three lengths a , b , c , the ratios of which can be determined from the direction angles, ξ , η , ζ , of its normal. From geometry

$$a : b : c = \frac{1}{\cos \xi} : \frac{1}{\cos \eta} : \frac{1}{\cos \zeta}.$$

The Miller indices $(h'k'l')$ of any other face can then be calculated from the direction angles ξ , η , ζ of its normal, by means of the following formula, which is but another statement of the law of Rationality:

$$h' : k' : l' = a \cos \xi : b \cos \eta : c \cos \zeta.$$

The direction angles are either measured or calculated from measured angles. The unit lengths a , b , c define a parallelepiped, which may be taken as the cell of a lattice. By a proper choice of the unit face, it is always possible to find a lattice for which the law of Bravais holds true. (Indeed this remark is the best statement of the law.) Before the advent of X-ray diffraction, this is how lattices were determined (Mallard, 1879 and especially G. Friedel, 1904). Some

morphological lattices were confirmed by X-rays; many turned out to be wrong, in the sense that they did not express the true periodicity of the crystal. The generalized law proved more powerful, leading not only to the lattice but to the correct space group in most cases.

Crystal Forms.—In a crystal point group, the assemblage of equivalent faces (hkl) is called a form $\{hkl\}$; for the assemblage of equivalent edges $[uvw]$ the word frame $\langle uvw \rangle$ has been proposed. The number of faces in a form is its multiplicity. The general form, that is, the form whose faces are not perpendicular to any symmetry element, has a multiplicity equal to the order of the point group. There exist 47 forms distributed among the 32 point groups. The lowest multiplicity is 1, the highest 48; the corresponding forms are called monohedron and hexaoctahedron. Other forms are: prisms, pyramids, dipyrramids, tetrahedron, cube, etc.

Space Groups.—The symmetry operations to be considered in space groups are those of the point groups, plus translations, plus screw-rotations and glide-reflections. These additional operations result from the combination of a translation with a rotation or a reflection. The corresponding symmetry elements are the screw axis and the glide plane. A screw axis is designated p_n ; the rotation angle is $360^\circ/p$ and the translation is equal to a fraction q/p of the lattice translation parallel to the axis ($q = 1, 2, \dots, p-1$). Screw axes are: $2_1, 3_1, 3_2, 4_1, 4_2, 6_1, \dots, 6_5$. A glide plane is designated a, b, c, n , or d according as the glide is equal to one half of a lattice translation along one of the axial vectors, one half of a face diagonal (n), or one fourth of a face diagonal (d) in the case of a centered face. The 230 space groups were independently discovered by E. Fedorov (1890) and A. Schoenflies (1891). W. Barlow nearly found them all (1894). In a crystal space group, the assemblage of equivalent atomic sites is called a position; the number of sites in a position is its multiplicity. The multiplicity of the general position is the order of the space group. It ranges from 1 to 192.

Reciprocal lattice.—The reciprocal lattice $a^*b^*c^*$ is a useful concept, defined as follows. At the origin of the crystal lattice (direct lattice), vectors a^*, b^*, c^* are erected perpendicular to the axial planes bc, ca, ab and on the same side of each axial plane as a, b, c , respectively. The lengths a^*, b^*, c^* are proportional to the mesh areas bc, ca, ab ; the factor of proportionality is normally taken as $1/V$, although other factors are sometimes used: $1/\sqrt{V}$, in Bravais' polar lattice; λ/V in Bernal's lattice, where λ is an X-ray wavelength (see 4. *Crystal Structure*). Two properties follow: (1) Any reciprocal-lattice vector $L^*_{hkl} = ha^* + kb^* + lc^*$ is perpendicular to the family of nets (hkl) of the direct lattice. (2) the length of L^* is equal to the reciprocal of the interplanar distance $d(hkl)$ in the direct lattice, $d(hkl) = 1/|L^*_{hkl}|$. If $h = nh', k = nk', l = nl'$, it is clear that $L^*_{hkl} = nL^*_{h'k'l'}$, where

$$L^*_{h'k'l'} = h'a^* + k'b^* + l'c^*,$$

so that $d(hkl) = d(h'k'l')/n$.

The law of Bravais can be expressed in terms of the reciprocal lattice: the shorter the reciprocal-lattice vector, the more frequent the corresponding face. Halving an interplanar distance means doubling the corresponding reciprocal-lattice vec-

tor, so that lattice or space-group criteria are expressed by missing nodes in the reciprocal lattice (morphological extinctions). Example: in an all-face-centered lattice abc , the nets ($h'k'l'$) for which the co-prime indices are not all odd have their interplanar distance halved (as compared to what it is in the primitive lattice). This is expressed by doubling the indices, which are thus made to obey the criterion "indices all even." The reciprocal-lattice nodes whose indices do not obey the criterion "all odd or all even" are "extinguished."

Twinning.—Besides occurring as homogeneous crystals, crystalline matter form heterogeneous edifices called twins. A twin is an assemblage of two or more crystals, symmetrical of one another with respect to a twin element. The twin operation brings crystal I to coincide with crystal II. It may be a rotation of $60^\circ, 90^\circ, 120^\circ$, or 180° about a twin axis; a reflection in a twin plane; or an inversion in a twin center. Several twin operations may exist simultaneously. The surface of junction of two crystals in a twin is called composition surface; it may be planar (contact twinning) or irregular (penetration twinning). Twinning may be dual (2 crystals) or repeated (more than 2 crystals); if repeated, it may be polysynthetic (parallel lamellae) or cyclic (crystals inclined to one another).

Twinning is found to occur when a net and a row happen to be either exactly or nearly perpendicular. The cell built on this net and this row is that of a lattice—the twin lattice—which expresses partial periodicity of the crystalline edifice. The twin lattice, either rigorously or approximately, has more symmetry than the crystal (or even than the crystal lattice); the symmetry operations that the twin lattice possesses and that the crystal does not possess can play the role of twin operations (G. Friedel, 1904). Example: pyrite, FeS_2 . Crystal symmetry, $2/m\bar{3}$. Crystal-lattice symmetry and twin-lattice symmetry, $4/m\bar{3}2/m$. All operations present in the second symmetry symbol and not in the first are simultaneous twin operations.

2. CRYSTAL OPTICS. Optical crystallography is concerned with the behavior of light transmitted or reflected by crystalline substances. The development of the theory is based on the unproved assumption that light consists of oscillatory wave motion resulting from a combination of propagation and vibration transverse to the direction of propagation. Routine observations utilize either a white light source or a monochromatic source emitting a single color of the visible spectrum. Special investigations have been made with energy sources producing ultraviolet or infrared radiations.

The basic tool for optical study of light-transmitting crystals is a polarizing microscope, which differs from an ordinary microscope in having a removable polarizing filter or prism called an *analyser* above and a fixed polarizing device called a *polarizer* below a rotatable stage. Microscopic optical studies of opaque materials are made in reflected light which can be made to pass through polarizing devices before and after reflection. Light passing through either

the analyzer or the polarizer is constrained to vibrate in a single plane and is described as *plane-polarized light*. In the polarizing microscope the analyzer is oriented so that when it is inserted its plane of polarization is perpendicular to that of the polarizer, and no light is transmitted by the microscope. However, crystals or fragments of most substances placed on the stage change the manner in which light is transmitted by the microscope and produce characteristic optical effects.

The optical constants, which in common with the other physical properties of crystals are characteristic and diagnostic for each substance, are measured or estimated with the aid of auxiliary lenses and calibrated optical accessories. The fundamental optical constants of nonopaque crystals are the *principal indices of refraction*, the *crystallographic orientation of the directions of light vibration corresponding to these indices of refraction*, and the *amount of absorption of light vibrating in these directions*, all expressed in terms of one or more standard wave lengths of light. Properties that may be predicted if the

Snell's Law, which states that $n = \frac{\sin i}{\sin r}$, where i is the angle of incidence of light entering a crystal and r is the angle of refraction of light by the crystal.

Another useful equation states that $v = f\lambda$, where v is the velocity, f is the frequency, and λ is the wave length. From this equation it is seen that the velocity of light is directly proportional to its wave length, and, inasmuch as the refractive index is inversely proportional to the velocity of light in a medium, it follows that the refractive index is also inversely proportional to the wave length of the transmitted light. The simplest expression of this fact is seen where white light enters a triangular glass prism and is split into the component colors of the visible spectrum. Light of shortest wave lengths (violet) is refracted (bent) the most, and long wave lengths (red) are refracted the least.

Variations in optical properties dependent on the refractive indices may be visualized with the aid of the optical indicatrix, a geometric form which in triclinic, monoclinic, and orthorhombic

Fig. 1. Biaxial indicatrices. Bxa = acute bisectrix; Bxo = obtuse bisectrix; CS = circular section; OA = optic axis.
Fig. 3. Hexagonal crystal showing orientation of indicatrix.

fundamental constants are known are birefringence, optic sign, optic axial angle, extinction angles, color, pleochroism, dispersion of the optic axes, and dispersion of the bisectrices. Properties determined for opaque substances are the color of the reflected light, rotation of the plane of polarization of incident light, and the nature of polarization figures.

The index of refraction (refractive index) is expressed by the equation $n = \frac{V_1}{V_s}$, where V_1 is the velocity of light in vacuum (or air) and V_s is the velocity in the light-transmitting medium. V_1 for light in the visible spectrum is always greater than V_s , and refractive indices always have values in excess of unity. If the velocity of light in vacuum is assumed to be unity, the equation for the refractive index becomes $n = \frac{1}{V_s}$, from which it is seen that the velocity of light traveling through a crystal is inversely proportional to the refractive index of the crystal. Useful in calculating the refractive index is

crystals is a triaxial ellipsoid, in hexagonal and tetragonal crystals an ellipsoid of rotation, and in isometric crystals a sphere. The indicatrix shows the refractive indices of light waves in their *directions of vibration* (transverse to the direction of propagation) for monochromatic light. For each wave length of light in a crystal there is a characteristic indicatrix with a particular orientation.

Figure 1 shows indicatrices of the type characteristic of triclinic, monoclinic, and orthorhombic crystals. The equation for the indicatrix is

$$\frac{x^2}{(n_x)^2} + \frac{y^2}{(n_y)^2} + \frac{z^2}{(n_z)^2} = 1,$$

where n_x , n_y , and n_z (also designated α , β , and γ) are the minimum, intermediate, and maximum dimensions of the indicatrix and correspond to the refractive indices of light waves vibrating parallel to the X , Y , and Z axes, respectively. The numerical difference between the values of n_x and n_z is the *birefringence*. Two circular sections have positions determined by the relative

values of n_x , n_y , and n_z . The optic axes are perpendicular to the circular sections and are directions along which all light waves of the same wave length move with constant velocity. Because there are two such directions, crystals in the triclinic, monoclinic, and orthorhombic systems are described as *biaxial*.

The angle $1'$ between the Z axis and an optic axis is calculated by the equation

$$\tan^2 V_z: \frac{(n_x)^2}{(n_y)^2} - \frac{1}{(n_z)^2} = \frac{1}{(n_y)^2} - \frac{1}{(n_z)^2}$$

If Z is the acute bisectrix, the crystal arbitrarily is described as *positive*, and if X is the acute bisectrix, the crystal is said to be *negative*. The angle $21'$ between the optic axes is the *optic angle*.

The orientation of the X , Y , and Z axes of the indicatrix in a biaxial crystal accords with the crystal symmetry, and is expressed by the angular relations between the crystallographic a , b , and c axes and the axes of the indicatrix. The axes of the indicatrix for a particular wave length in a triclinic crystal occupy a fixed position but, in general, are not parallel to any of

Fig. 2. Uniaxial indicatrices. Fig. 4. Indicatrix for an isometric crystal.

the crystal faces or axes. In monoclinic crystals having a plane of symmetry, X , Y , or Z is parallel to the b crystal axis, and the other two axes lie in the plane of symmetry. In orthorhombic crystals the X , Y , and Z axes are parallel to the mutually perpendicular crystallographic axes.

In hexagonal and tetragonal crystals the equation for the indicatrix is

$$\frac{X^2 + Y^2}{(n_o)^2} + \frac{Z^2}{(n_e)^2} = 1$$

and represents a special case where the optic angle of the biaxial indicatrix has been reduced to zero. Light waves move with constant velocity in only one direction, the direction of the optic axis (Fig. 2), and such crystals are described as *uniaxial*. The refractive indices corresponding to light vibrating parallel to the optic axis and parallel to a radius of the circular equatorial section are designated n_e and n_o (ϵ and ω), respectively. The optic axis is parallel to the c crystallographic axis in all tetragonal and hexagonal crystals (Fig. 3). By definition n_o is greater than n_e in optically positive crystals; the reverse relationship holds for negative crystals.

The indicatrix is a sphere in isometric crystals (Fig. 4) and light of a single wave length travels with equal velocity in all directions through the crystal.

Crystals with two or three principal refractive indices are described as *anisotropic*. Any radius of the indicatrix gives the refractive index of the light wave vibrating along it, and, inasmuch as in anisotropic substances the various radii have different values, waves transmitted in different directions have different velocities.

Experimental observation of anisotropic crystals proves that, except in the directions of the optic axes, the transmitted light consists of two components which vibrate in mutually perpendicular planes and travel with different velocities. The polarizing microscope is capable of detecting this fact, and by a complex process of resolution and composition of the light transmitted by the crystal and by the microscope yields characteristic interference phenomena. A typical anisotropic crystal viewed under the polarizing microscope in white light produces an interference color that is a function of the phasal difference of the two components of transmitted light and during a 360-degree rotation of the microscope stage diminishes to minimum intensity (dark-

ness) four times at the so-called *extinction positions*. Extinction results when appropriate directions of the indicatrix coincide with the mutually perpendicular planes of polarization of the polarizing devices above and below the microscope stage. Measurements of angles between crystallographic planes or directions and positions of extinction yield *extinction angles*, which are useful in determining the orientation of the indicatrix in the crystal. Isometric (isotropic) crystals remain black for all positions under the microscope.

In triclinic and monoclinic crystals the indicatrices occupy different positions for different colors (wave lengths) of light and produce a phenomenon described as *dispersion of the bisectrices*. Moreover, in all biaxial substances the optic angles change as a function of the wave length of light and produce *dispersion of the optic axes*. Fig. 5 illustrates both types of dispersion in a monoclinic crystal in which indicatrices for red and blue, at opposite ends of the visible spectrum, have different orientations and different optic angles.

Viewed in the plane-polarized light transmitted by the polarizer and with the analyzer removed, many anisotropic substances change

Fig. 5

Fig. 5. Monoclinic crystal showing indicatrices for red and blue light. Note that indicatrices have different orientations and different optic angles. $2V$ = optic angle; OA = optic axis.

color as the microscope stage is rotated. This phenomenon depends on differential absorption of light in different directions in the crystal and is described as *pleochroism*. According to common practice the colors or the relative amounts of absorption that are observed for light vibrating parallel to the X , Y , and Z axes of the indicatrix when a white light source is used are noted and expressed by means of a *pleochroic formula* or an *absorption formula*. Thus, the pleochroic formula for a particular substance might be X = light green; Y = medium green; Z = dark brown; or the absorption formula might be expressed as $X < Y < Z$.

The polarizing microscope is converted to a conoscope by inserting a lens of short focal length below the stage and a Bertrand-Amici lens just below the ocular system. The conoscope permits observation of phenomena depending on the interference of light waves incident on the crystal in a converging cone. Under the conoscope anisotropic substances yield interference figures which are characteristic of each substance and permit determination of the optic orientation, optic sign, axial angle, dispersion of the bisectrices, and dispersion of the optic axes. Inter-

ference figures consist of dark brushes called *isogyres* superimposed on color curves. Uniaxial crystal sections cut at right angles to the optic axis yield an isogyre in the form of a black cross (Fig. 6) in all positions of rotation of the microscope stage. Isogyres in biaxial crystals change position and configuration in a manner dependent on the optic angle and the orientation of the crystal under the microscope as the microscope stage is rotated (Fig. 7).

A variety of techniques is used for measuring the optical properties of crystals. A widely used method employs liquid immersion media of known refractive indices. Fragments or whole crystals are immersed in successive liquids until a particular refractive index is matched by the index of the immersion medium. This condition is reached when there is no refraction of light at the liquid-crystal contact. Measurement of extinction angles, observation of absorption colors, and examination of interference figures permits determination of many or all of the other optical properties. The immersion method is rendered more versatile by taking advantage of the fact that the refractive index of the immersion medium changes with temperature and the wave length of the light source, so that it is possible to match crystal and liquid indices with fewer immersions by controlling the temperature and the light source. The universal stage, a multiaxis device that is mounted on the microscope stage, permits controlled rotation of mounted crystals or fragments into any desired position.

Aggregates of crystals such as those in rocks are studied most successfully in thin sections: plates of the aggregate ground to a thickness of 0.03 mm. and mounted with adhesive cement on a glass slide.

Standard accessory equipment for the polarizing microscope consists of a variety of calibrated devices which enable measurement of phasal difference or produce effects which are a function of the orientation and phasal difference produced by a crystal.

of calcium carbonate, first attracted attention. This material cleaves into transparent blocks which when placed on, for instance, a printed card, produce two images of each printed letter. This property is due to the *double refraction* of the calcite. The optical properties of many types of crystals were studied during the next century and a half and about the middle of the 19th century attention began to be paid to the other physical properties of crystals. The discovery of the way of making an electromagnet led to the study of the magnetic properties of crystals. A natural consequence of this work was the investigation of the electric properties. The development of optical devices for measuring very small changes in length led to the study of the thermal expansion of crystals. At the end of the 19th century the brothers Curie discovered the *piezoelectric* properties of certain crystals and with their application to submarine detection in World War I these properties were most intensively studied in the following years. The mechanical properties of crystals were first studied about the middle of the 19th century. Calcite crystals show the remarkable property of gliding under suitable stresses, as though the structure were like a pack of cards. The phenomenon is known as *plastic deformation* and the study of it became more common after the discovery early in the 20th century of the manner in which molten metal can be cooled so as to produce single crystals. The elastic properties of non-metallic crystals were studied in an academic way at the beginning of the 20th century but, after the important applications of piezoelectricity were made, these properties were studied more intensively because without a knowledge of them the piezoelectric instruments could not be properly constructed. In the early experiments on radio, crystal detectors were used and the *rectifying properties* of various types of crystal have become of great practical importance today.

The physical properties of crystals are distinguished from those of ordinary solid materials by their relation to the symmetry of the crystal. The symmetry also determines the number of coefficients which are needed to define a given property. Thus, for instance, a crystal of calcium thiosulphate, with no axes of symmetry, has eighteen piezoelectric constants, but one of quartz, with several axes of symmetry, has only two such constants. A special type of mathematics—the tensor calculus—is especially valuable in working out the number of physical constants, which are required by the symmetry.

The atomic arrangements are responsible for the differences between crystals and non-crystalline matter. It is difficult, however, to calculate from the known properties of atoms and their known arrangements what physical properties will be found. Some progress has been made but as yet only a partial understanding of this relation exists.

Thermal Properties.—*Thermal Expansion.*—A sphere cut from a cubic crystal remains a sphere after changing its temperature. A sphere cut from a uniaxial crystal changes into an ellipsoid of revolution and one cut from a biaxial crystal becomes a tri-axial ellipsoid. There is only one *thermal expansion coefficient* (change of length per unit length per unit change of temperature) for a cubic crystal; uniaxial crystals have two *principal expansion coefficients* which refer to the axis of the ellipsoid of revolution

and any perpendicular direction passing through the center respectively; biaxial crystals have three principal expansion coefficients associated with the three mutually perpendicular axes of the triaxial ellipsoid. Some crystals, e.g. calcite, expand in one direction while contracting in others. In such a case there are some directions in which the crystal neither expands nor contracts with change of temperature. The expansion of iron bridges in summer, and the expansion of the metal leads into electric lamps during manufacture, are examples of the importance of the expansion of poly-crystalline materials.

Thermal Conductivity.—The same relations hold between the *coefficients of thermal conductivity* and the symmetry as apply to thermal expansion. This conductivity coefficient is defined as the heat flow per second per unit area in a given direction per unit temperature gradient. If heat is supposed to flow outwards from a point within a crystal towards boundaries which are far off, the points at which the temperature is the same lie on an *isothermal surface*. Such surfaces are in general triaxial ellipsoids but in uniaxial or cubic crystals they become ellipsoids of revolution and spheres respectively.

Thermo Electricity.—When a block of electrically conducting crystal is held between ordinary metal plates maintained at different temperatures a *thermo electro-motive-force* is established across the crystal. The coefficients of this property obey the same symmetry relations as those of thermal conductivity. The thermo e.m.f.s. generated by crystals are often strongly dependent on small amounts of impurities or mechanical strain or disorder in the arrangement of the lattice.

Magnetic Properties.—*Diamagnetism.*—A *diamagnetic crystal* when placed in a non-uniform magnetic field tends to move towards the region of weaker field strength. Most crystals are of this kind with the exceptions mentioned below of the *para-* and *ferro-magnetic* crystals. The *magnetic susceptibility* is defined, for a given direction in the crystal, as the magnetic moment per unit volume induced by unit magnetic field strength when both the induced moment and the applied field are measured in the direction specified. Like the properties of thermal conductivity etc., this is also represented by a second order tensor and obeys identical symmetry laws. Certain organic crystals show a simple relation between the coefficients of susceptibility and the crystal structure and much use has been made of this in checking structures determined by X-rays.

Paramagnetism.—A *paramagnetic crystal* when placed in a non-uniform magnetic field tends to move towards the region where the field is stronger. Crystals containing ions of transition elements such as Cu^{2+} , Fe^{2+} etc. and rare earth ions such as Y^{3+} , Ce^{3+} etc. show this property. The paramagnetic susceptibility is not related to the atomic arrangement in the same direct way as the diamagnetic susceptibility but depends on the character of the individual ions. The environment of these ions in some cases mainly determines the property of the whole crystal.

Ferromagnetism.—A *ferromagnetic crystal* when placed in a non-uniform field tends to move with great force towards the stronger parts of the magnetic field. The forces involved with these materials are usually thousands of times greater

than those obtained with either para- or diamagnetic crystals.

Symmetry operates in determining the variation of the ferro-magnetic susceptibility with direction but the laws are more complicated than those which apply to the second order tensors. Lodestone, which is a magnetic oxide of iron, Fe_3O_4 , has from ancient times been used by sailors as a magnetic compass. In modern times the whole basis of electrical machinery depends on the magnetic properties of iron and some of its alloys. To an ever increasing extent applications are being made of the special directional properties of single crystals of these magnetic materials.

Electrical Properties.—*Electrical Conductivity*—The coefficients of electrical conductivity or resistivity for metallic single crystals vary with direction of current flow in accordance with the symmetry requirements in the same way as the coefficients of thermal conductivity mentioned above. Most ordinary metals are cubic but magnesium, zinc, cadmium, among others, are hexagonal and tin is tetragonal.

Piezoelectricity.—When certain non-conducting crystals are compressed they develop electric charges of opposite sign on opposite sides of the crystal. This property is known as *piezoelectricity*. Such crystals also expand or contract when subjected to an electric field. This property can only be shown by a crystal lacking a center of symmetry. The constants which define the property of piezoelectricity are called third order tensors because they relate a first order tensor (the electric moment produced) to the stress applied (a second order tensor). The number of such constants varies from 18 to one, according to the degree of symmetry present. Crystals of quartz, SiO_2 , and several other materials, are cut and ground accurately to size so that their frequencies of mechanical vibration have given values. These crystals are used in conjunction with oscillatory electrical circuits to generate alternating current of known and very constant frequency. When used in this way they are known as *piezoelectric oscillators* and find application in special clocks, and in radio transmitting and receiving stations. When a single telephone cable is used to transmit simultaneously several hundred telephone messages, crystals of this sort are often used to separate the messages from one another. This is done by electrical filters and the crystals in them are called *piezoelectric resonators*. When such crystals are caused to oscillate in a liquid they generate mechanical waves which on account of their high frequency are called *supersonic*. Such waves have uses in submarine sounding, in ageing whisky, in laundering clothes, and in locating cracks in metallic objects.

Ferroelectricity.—Certain crystals lacking a center of symmetry show the property of becoming spontaneously electrically polarised in the same sense over relatively large volumes. This phenomenon can give rise to dielectric constants of abnormally high value, say 10^4 , and also to abnormally large piezoelectric charges. By analogy with ferromagnetic crystals such materials are called *ferroelectric*. Rochelle salt, $\text{NaKC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ and barium titanate, BaTiO_3 , are examples of this sort of material. The large values of the piezoelectric constants of ferroelectric crystals make them very valuable for certain applications in which a small mechanical force is required to produce a large electric charge.

Pyroelectricity.—Certain crystals develop electric charges of opposite sign at opposite ends being heated. Such crystals are called *pyroelectric*. This property is shown by many piezoelectric crystals and is in part due to the same atomic movements which give rise to the piezoelectricity. It is of no importance except in the study of crystal structure. If a crystal can be shown to be pyroelectric it must lack a centre of symmetry and this is often an essential piece of information in determining the atomic arrangement.

Dielectricity.—All insulating crystals when placed in an electric field become electrically polarised. This polarisation is subject to the same laws of symmetry as other second order tensors. If the capacities of a parallel plate condenser when the plates are separated (1) by the crystal, (2) by air, are C_1 and C_0 respectively, then the *dielectric constant* for the direction perpendicular to the surfaces of the crystal plate is C_1/C_0 . This constant varies between a few units up to ten for usual dielectrics but for ferroelectric materials it may reach the order of 10^4 at certain frequencies and temperatures.

Semiconducting Crystals.—Many crystals have conductivities well below those of ordinary metals and much in excess of those of normal insulators. Such crystals are known as *semiconductors*. The conduction is closely dependent on small changes of chemical composition, on the presence of impurities, on defects in the growth of the crystal or on the externally applied stresses. Many crystals of great practical importance fall into this group. The rectifying crystals such as cuprous oxide, Cu_2O , or selenium, are used in electrical engineering on a large scale; galena, PbS , crystals as well as many other such crystals, are used as "cats-whisker" rectifiers in primitive radio receivers and crystals of germanium and silicon are receiving much application as transistors.

Mechanical Properties.—*Elasticity*.—When subjected to mechanical stresses crystals change their shape i.e. they develop strains. The coefficients relating stresses and strains define the elasticity. The number of such constants varies from 21 when the crystal has no symmetry down to three when it has the maximum symmetry possible, namely cubic symmetry. Elastic constants may be measured in a variety of ways. If large specimens can be cut into plates or bars they can be bent or twisted by known forces and the amount of deformation measures the elasticity. If they can only be had in small pieces supersonic waves are used to cause them to vibrate. From the dimensions of the crystal and the natural frequency of its vibration the elastic properties can be determined.

The elasticity of crystals is studied partly for its own sake but principally to make it possible to fashion in the best manner various piezoelectric oscillators and resonators. The elastic properties of polycrystalline metals have great technical importance. The knowledge of the elasticity of single crystals of these metals is likely to throw much light on certain metallurgical problems.

Plasticity.—A large number of single crystals when subjected to stresses above a certain limit become permanently deformed. Such crystals are said to be *plastic*. Perhaps the most striking example of this phenomenon is afforded by a single-crystal wire of cadmium or zinc. Whereas a polycrystalline wire of the same material will not lengthen permanently until a certain force

is applied to it, if the material is made into a single crystal it may deform permanently under a stress one hundredth, or less, of that required to deform similarly the polycrystal. A plastic single crystal usually changes its shape in the way to be expected if it consisted of a number of lamellae all parallel to a *glide plane*, parallel to which they can all move relatively easily. The lamellae are only free to move in one direction, known as the *glide direction*, lying in the glide plane. One geometrical consequence of this is that a cylindrical wire on being pulled out usually develops an elliptical cross-section. Plasticity is usually associated with the property of *work-hardening* so that the more the crystal is deformed the greater is its resistance to the deforming force. The combination of the two properties of plasticity and work-hardening gives many metallic materials their technically useful character.

4. CRYSTAL STRUCTURE. The useful magnification which can be attained with optical microscopes is limited by the wavelength of visible light (ca. 4,000 to 7,500 Å.) and, as a result, objects less than about 2,000 Å apart cannot be resolved even with the best optical microscopes. Atoms in solids are often less than 2Å apart. In order to study their arrangements directly, we must use radiation having wavelengths comparable to interatomic distances. X-rays, having wavelengths from about 0.5 to 2.5Å are well suited for this purpose. X-rays cannot be focussed by lenses, but they are scattered by atomic electrons, and a wide variety of information about atomic structure can be obtained by studying these scattered X-rays. This method, the X-ray diffraction method, is used to determine atomic arrangements, interatomic distances and bond angles in crystals; it is also widely used for the identification of crystalline materials and for measurements of particle size, stresses and preferred orientation in crystalline solids.

Elements of Crystallography (See 1. *Crystal Morphology*).—Although X-rays can be used to study matter in any state of aggregation, they are most profitably employed in investigations of crystalline solids. For such investigations, some familiarity with crystallographic nomenclature is essential; a few of the more commonly used terms are defined below:

A *crystal* consists of atoms arranged in a pattern which is repeated regularly in three dimensions. The individual repeat unit may consist of one or many atoms; successive repeat

units are identical in orientation as well as composition. It is often useful to replace each repeat unit by a representative point, a *lattice point*. The collection of lattice points is the *space lattice*, or the *lattice*. A network of parallel lines passing through the lattice points can be shown dividing the lattice into identical parallelepipeds; these are the *unit cells* of the crystal. The crystal may then be thought of as a collection of identical unit cells, stacked in three dimensions.

The arrangement of the lattice points is always the same for a given crystal, but they may be joined in an infinite number of ways. There is a corresponding infinite number of ways of choosing a unit cell; it is only necessary that it contain at least one complete repeat unit of pattern. The actual choice of the unit cell is generally dictated by convenience.

There are only 14 distinct ways in which points can be arranged in space so that all points have identical environments. These are the 14 space lattices. Each space lattice has some convenient set of axes with respect to which atomic locations can be given. Seven different systems of axes are used in crystallography. These form the basis of the seven *crystal systems*: cubic, hexagonal, rhombohedral, tetragonal, orthorhombic, monoclinic and triclinic. If there is only one lattice point per unit cell, the lattice is designated as *primitive*. It is sometimes desirable to refer the crystal to a lattice whose cells contain more than one unit of pattern; in addition to lattice points at the corners, the cells may have lattice points at the centers of some or all the faces. There are seven such centered space lattices.

The fundamental repeat unit of structure often consists of a number of sub-units, identical in atomic composition but differing in orientation. These sub-units are generally related to one another by means of symmetry elements. The symmetry elements are of two types. In one class are symmetry elements, or operations, which leave the point which is operated on unmoved. In three dimensions these include *inversion* about a point, *rotation* about an axis, and *reflection* across a plane. There are altogether 32 ways of combining these symmetry elements in crystals; these are the 32 *crystal classes* or *point groups*. There are, in addition, elements of symmetry which involve translation, as well as rotation and reflection; these are the screw axes and the glide planes. The combination of these elements with the 32 point groups in the 14 space lattices leads to 230 *space groups*. A space group may be viewed as a set of rules whereby the contents of the entire unit cell may be generated from one asymmetric unit of structure. All 230 possible space groups have been listed and described.

The modern nomenclature for the space groups (Hermann-Mauguin) utilizes symbols from which the space group may be directly derived. First is listed the lattice type: P refers to a primitive cell; A, B, C are face centered on the A, B, C, faces respectively; F is centered on all faces, I is body centered. Additional symbols, numbers or letters, refer to the symmetry elements associated with significant crystallographic directions.

If a model of a space lattice is rotated, it can be seen that the lattice points may be considered to lie in sets of parallel planes. Any such set can be identified by the three Miller in-

lices (hkl). Consider any such set of parallel planes. They cut the a , b and c axes into different numbers of parts. If " a " is divided in " h " parts, " b " into " k " and " c " into " l " parts, then the Miller indices of that set of planes are hkl . These same indices are used to denote X-ray reflections from that set of planes.

Geometry of X-Ray Diffraction.—When a beam of X-rays sweeps over an atom, all the electrons oscillate with the frequency of the incident X-rays; secondary "scattered" X-rays of the same wavelength as the incident X-rays are then radiated in all directions. Von Laue has shown that when the scattering units are present in a regular, three-dimensional array, as in a crystal, the scattered X-rays interfere destructively and cancel each other in most directions; in certain special directions there can be constructive interference, the waves may reinforce one another, and strong diffracted beams may be observed.

The relation between the directions of the diffracted beams and the arrangement of scattering units in the crystal is difficult to visualize in terms of von Laue's treatment; it is more readily understood on the basis of a simple model of the diffraction process proposed by W. L. Bragg.

A monochromatic beam of X-rays, of wavelength λ , is considered to be incident, at an angle θ , to a set of parallel lattice planes spaced equal distances, " d " apart in a crystal. (Fig. 1).

Fig. 1. Bragg's Law.

The path difference for rays reflected from adjacent planes is $2d \sin \theta$. Reinforcement of the radiation reflected from successive planes occurs when the path difference is an integral number, n , of wavelengths, i.e., when $n\lambda = 2d_{hkl} \sin \theta$. This is Bragg's Law.

In general for any arbitrary incident angle, the reflections from successive planes are out of phase with one another; destructive interference occurs and no diffracted beam can be observed. However, θ can be varied by changing the orientation of the crystal relative to the x-ray beam until the conditions for constructive interference are satisfied. The angle between the incident and the reflected beams is then 2θ . The spacings, " d ", of the reflecting planes can be easily computed, using Bragg's Law. These calculations are based on measurements of the directions of the diffracted beams, which are determined entirely by the size and shape of the unit cell. On the other hand, the relative intensities of the reflections depend on the contents of the unit cell, on the number, type and distribution of the atoms in the unit cell.

Atomic Scattering Factor.—We consider, first, the manner in which the scattering power of an atom is built up from the contributions of its electrons, and then the manner in which the diffracted beam is made up from the cooperative scattering by the atoms in the unit cell.

To express the ability of an atom to scatter X-rays, we use the quantity f , the *atomic scattering factor*, which is simply the ratio of the amplitude of the wave scattered by an atom to that scattered by one electron under the same conditions. The atomic scattering factor obviously varies with the number of electrons in the atom. It also varies with angle, decreasing steadily as the angle between the incident and diffracted beams increases. This results from the fact that at small diffraction angles the individual waves scattered from the electrons in the atom are nearly in phase and reinforce one another; they fall more and more out of phase and destructive interference increases, as the angle is increased.

Structure Amplitude.—To compute the total intensity of a reflection, it is necessary to sum up the waves scattered in a given direction from all the atoms. This is equivalent to the problem of adding sine waves different in amplitude and phase, but having the same wavelength, in order to determine the amplitude of the resultant wave. Differences in amplitudes of the individual waves result from differences in scattering power of the various atoms; the relative positions of the atoms along the path of incident and diffracted beams determine the relative phases of these waves. It can be shown that the intensity of the diffracted wave is, in general, proportional to the square of the resultant amplitude. The *structure amplitude*, F_{hkl} , for a given (hkl) reflection, is equal in magnitude to the resultant amplitude divided by the amplitude of the wave scattered by a single point electron for the same wavelength. It is a measure of the efficiency of the set of planes (hkl) in reflecting x-rays.

The value of the structure amplitude can be written as:

$$F_{hkl} = \sum f_j e^{i\phi_j} \quad (1)$$

where the sum extends over all atoms in one unit cell and ϕ_j is the phase of the wave scattered by atom j relative to a wave scattered by an atom at the origin. If the coordinates of the j th atom are x_j, y_j, z_j , where x_j, y_j, z_j are expressed as fractions of the unit cell dimensions, then it can be shown that for a given reflection, (hkl)

$$\phi_j = 2\pi (hx_j + ky_j + lz_j) \quad (2)$$

$$\text{and} \quad F_{hkl} = \sum_j f_j e^{2\pi i (hx_j + ky_j + lz_j)} \quad (3)$$

This can be written as:

$$|F_{hkl}|^2 = \left| \sum_j f_j \cos 2\pi (hx_j + ky_j + lz_j) \right|^2 + \left| \sum_j f_j \sin 2\pi (hx_j + ky_j + lz_j) \right|^2 \quad (4)$$

Equation (3) reduces to a simpler form when the crystal has a center of symmetry which is chosen as the origin of the unit cell, i.e.

$$F_{hkl} = \sum_j f_j \cos 2\pi (hx_j + ky_j + lz_j) \quad (5)$$

Using equations based on (4) and (5) it is possible to compute the intensity of an x-ray reflection (hkl) when the atomic distribution in the unit cell is known.

Reciprocal Lattice.—Corresponding to every real lattice, there is a "reciprocal" lattice, which has the same symmetry as the real lattice and can be referred to the same type of coordinate

axes. The interpretation of X-ray diagrams, particularly those of single crystals, is greatly simplified if the crystal is described in terms of such a reciprocal lattice. To construct the lattice reciprocal to any given space lattice, an arbitrary point is chosen as origin. From it normals are drawn to all sets of direct lattice planes, (hkl). Points are then laid off along these normals at distances K/d_{hkl} from the origin, where K is a constant and d_{hkl} is the interplanar spacing of the planes (hkl). This array of points constitutes a lattice. Each reciprocal lattice point, therefore, represents a set of reflecting planes in the crystal; the indices of the set of planes (hkl) are the coordinates of the corresponding point in reciprocal space. Generally K is taken as unity (sometimes as λ).

The use of the reciprocal lattice makes possible the indexing of diffraction films in a simple, natural way. It also shows clearly the spacings of sets of reflecting planes in the crystal and with the aid of a simple geometrical construction, permits an easy, physical visualization of the process of diffraction by crystals. Consider a sphere that touches the origin of the reciprocal lattice and which has a radius equal to the reciprocal of the X-ray wavelength used (Fig. 2). The diameter, ACO, is parallel to the incident

Fig. 2. The sphere of reflection

X-ray beam. It can easily be shown that a set of planes (hkl) will be in reflecting position when, and only when, the corresponding reciprocal lattice point lies on the surface of this sphere. Under these conditions the angle between the lines ACO and CP equals 2θ , and the line CP is the direction of the diffracted beam.

The critical character of Bragg's Law is now apparent. It can be seen that, for an arbitrary orientation of the crystal relative to a monochromatic X-ray beam, no points of the reciprocal lattice will lie on the sphere of reflection and there will be no diffracted beam. As the crystal is rotated, points of the reciprocal lattice pass through the surface of the sphere and the directions of the reflected rays will be from C to the reciprocal lattice points where they pass through the surface of the sphere. It is clear, too, that reflections from crystals with large unit cells and with correspondingly small reciprocal cells, will be close together on the film.

Experimental Methods.—All types of X-ray apparatus have certain characteristics in common: a system of slits (collimators) to define the X-ray beam; means for holding, orienting and rotating the specimen in the X-ray beam; and radiation sensitive devices, usually film or Geiger counters, to record the scattered radiation.

A. The Powder Method.—In the powder method, a small sample containing a large number of small, randomly oriented crystals, is placed in the path of a collimated beam of monochromatic or filtered X-rays (see X-RAY, PHYSICAL NATURE OF). The sample is usually a finely ground powder prepared in the form of a cylinder and mounted with its axis perpendicular to the X-ray beam. When a set of planes in any crystal makes the correct angle with the incident beam to satisfy Bragg's Law, diffraction occurs. The sample (if cylindrical) is generally rotated about its axis during the exposure to ensure maximum randomness of orientation of its component crystallites. These make all possible angles with the incident beam and therefore all possible reflections will occur. For each set of planes with spacing d_{hkl} , there will be a set of diffracted beams describing a cone of half apex angle $2\theta_{hkl}$. The intersection of these cones with the film gives the powder pattern; if a flat film, perpendicular to the X-rays is used, the result will be a series of concentric circles; if cylindrical film is used, the powder pattern will consist of more complicated curves. In place of film, a Geiger counter, or similar device, may be made to traverse a path around the specimen in order to record the scattered radiation; special specimen mounts are generally used in such cases. (See X-RAYS, APPLIED.)

The powder method is used mainly in applied problems, for identification of crystalline solids, for precise measurements of lattice constants and for particle size determination.

Every crystalline substance gives a unique diffraction diagram characterized by the spacings of the lines and their relative intensities. These patterns can obviously be used for identification purposes. All that is needed is a properly indexed catalogue of patterns of known substances, such as the card index of the American Society for Testing Materials, which lists the patterns of about 5,000 compounds. Identification of the components in the sample is accomplished by comparing the d spacings and intensities of lines of the powder pattern with those in the catalogue. X-ray identification of industrial materials by the powder method is extensively used in the metallurgical, ceramic and chemical industries.

In studies of expansion coefficients, phase diagrams and solid solutions, slight changes in lattice dimensions must be followed. In such cases one studies reflections in the "back reflection" region, at Bragg angles close to 90° . It can be seen, from Bragg's Law, that when θ is close to 90° , small changes in " d " (or $\sin \theta$) correspond to large changes in θ . With reasonable care it is possible, using reflections in the back reflection region, to determine lattice dimensions to better than 1 part in 25,000. Very small relative changes are, therefore, easily detected.

The powder method is also used widely in industry for particle size studies. It can be shown that when individual particles are smaller than about 500A in diameter, the diffraction lines become broader. It is possible to determine particle size from quantitative studies of line shapes; this has been done extensively with carbon blacks and a number of catalytic powders.

B. Single Crystal Methods: 1. The Laue Method.—In this method a continuous range of wavelengths is used; generally this is furnished by the output from a tungsten target tube operated at about 50 kv. The collimated beam strikes a stationary single crystal and the dif-

fracted beams are recorded on photographic film. A set of planes will diffract if the angle θ with the incident beam is such that the wavelength λ required by Bragg's Law is contained in the incident beam.

The diffraction pattern is generally recorded on flat photographic film. In the transmission method, a small crystal is used and the film is placed so that the crystal lies between it and the X-ray tube. In the back reflection Laue method, the film is placed between the tube and the specimen, the collimator passing through a hole cut in the film.

The latter method is widely used in determining the orientation of single crystals, especially those belonging to the more symmetrical systems. In back reflection Laue patterns of such crystals the symmetry of the pattern is often readily recognizable; adjustment of the crystal to achieve proper alignment is then easily made. The method is particularly useful in studies of crystals of metals and alloys, many of which crystallize in the cubic and hexagonal systems.

2. Rotation and Oscillation Methods.—In the customary rotation or oscillation single crystal techniques the crystal is mounted so that the axis of rotation is parallel to a crystallographic axis, i.e., parallel to a line of lattice points. Normal to any crystallographic axis there is, in the reciprocal lattice, a set of parallel planes of reciprocal lattice points. As the crystal rotates the reciprocal lattice rotates about an axis which is parallel to the crystal rotation axis and which passes through the origin of the reciprocal lattice. Layers of reciprocal lattice points will intersect the sphere of reflection in parallel circles. The directions of the reflected beams are from C (Fig. 2) to points in the circles. The reflections will be the elements of a series of right circular cones. If a cylindrical film, coaxial with the rotation axis, is used to record the reflections, the intersections of these cones with the film cylinder will be a series of parallel circles. When the film is straightened the reflections lie on a series of parallel, straight "layer lines." If a flat film is used, the layer lines will be a series of hyperbolae. The periodicity along the rotation axis can be readily computed from the separations of these layer lines. Indexing of reflections on layer lines is greatly simplified if the crystal is oscillated through a limited angular range (often 15°) in place of complete rotation. Adjacent regions of reciprocal space are recorded on successive films; each photograph contains relatively few reflections.

3. Moving Film Methods.—Indexing of single crystal diagrams is simplified further if moving film methods are used. The Weissenberg and precession methods are the most widely used. These are designed to record one layer of the reciprocal lattice at a time; this is achieved by screening out all but one layer of reflections with the aid of a metal screen having a slot set to pass only one layer line from the crystal to the film. In both methods the motions of the crystal and film are ingeniously coupled; the Weissenberg X-ray pattern is a slightly distorted version of the reciprocal lattice layer; on the precession photograph the reciprocal lattice layer appears in completely undistorted form.

Crystal Structure Determination.—It has been shown that it is possible to compute the amplitudes and therefore the intensities of reflec-

tions to be expected from any assumed structure. Many simple structures have been solved by this "trial and error" method; reasonable structures are assumed on the basis of chemical and physical considerations concerning atomic sizes and probable molecular configurations. The structure which gives best agreement between observed and computed intensities is considered the correct structure.

Clearly, this "trial and error" method can be used only for very simple structures. To determine crystal structures of greater complexity, an elegant method is available: the method of Fourier series. The electron density, ρ , in a crystal is a periodic function in space. It can therefore be represented by a three dimensional Fourier series as follows:

$$\rho(x,y,z) = \text{constant} \times \sum_{-\infty}^{\infty} \sum_{-\infty}^{\infty} \sum_{-\infty}^{\infty} F_{hkl} e^{-2\pi i(hx+ky+lz)}$$

where x,y,z are the coordinates of any point in the unit cell and F_{hkl} are the amplitudes of the various (hkl) reflections. These are proportional to the square roots of the reflection intensities.

The Fourier expression and the consequent calculations are simplified if the crystal has a center of symmetry at which the origin of the unit cell is placed. Even in this favorable case the summation of a Fourier series for an average crystal is a formidable task and, in recent years, many electronic computers have been designed to perform these calculations.

The results of a Fourier summation are generally plotted by using contour lines; the plot resembles the usual topographic contour map, the peaks representing regions of high electron density, hence atoms.

One major difficulty is inherent in the Fourier method of crystal structure determination. The experimental data consist of X-ray intensities; these are quantities proportional to $|F|^2$. From these we can only determine the absolute magnitudes of the Fourier coefficients. However, $|F|$ is, in the general case, a complex number (eq. 6), and even in the centrosymmetrical case, it is a number whose sign is either plus or minus. To perform a Fourier summation successfully, an approximate knowledge of the structure is generally needed. This can be used to compute the phase angles or signs of the Fourier coefficients which then can be used to compute the Fourier series.

Lacking such advance knowledge of the phase angles (which may be based on comparisons with known structures of similar substances or perhaps a good guess) the Fourier expressions for electron density cannot be used and recourse must be had to other methods of analysis. These are discussed in detail in the works listed in the bibliography.

CRYSTALS, Synthetic. A crystal grows by the orderly accumulation of the atoms of which it is composed. In a single crystal a given arrangement of atoms is repeated many thousands of times, always parallel to itself, like the pattern in wallpaper, but in three dimensions. This orderly accumulation has gone on under a wide variety of conditions in nature. Nearly all rocks are composed of crystals, large in coarse-textured rocks, small in fine. When crystals grow in the laboratory under conditions provided by man, they are called synthetic crystals. They may be more or less perfect than crystals of the same substance grown in the earth's crust, depending on the extent to which conditions favorable for their growth have been provided in the two cases. Many crystals grown in the laboratory are never found in nature.

The scope of this article is limited to consideration of single synthetic crystals, since a discussion of synthetic crystallization of polycrystalline bodies would involve such wide fields as, for example, the manufacture of cement, steel, paint and pottery.

When a single crystal grows, it nearly always develops smooth, planar faces whose angular relation to each other is governed by the regular arrangement of the atoms of the crystal. These angles are therefore always the same for a given substance although the relative sizes of the faces may vary from crystal to crystal. Usually crystals of a given substance will be similar in "habit" or proportions, that is, they will all be platy or all needle-like or all equi-dimensional. However, by varying the conditions of growth, this habit can be markedly changed (though the interfacial angles must, of course, remain unaltered). The reader is referred to the work of H. E. Buckley and others for many interesting habit modifications.

History.—Synthetic crystals were described in the 18th century by Domenico Guglielmini in his work (published 1705) on the shapes of crystals formed by evaporating solutions of

salts in the laboratory, but the effort to produce a crystal as an end in itself probably began in the 19th century with the work of such versatile experimenters as Senarmont, Hautefeuille, Mari-gnac and von Rammelsberg.

Demand.—There is considerable theoretical interest in the conditions and processes of crystal growth on the part of geologists, chemists and physicists, but, in addition to this, there is a two-fold demand for the finished product.

First, single crystals are needed for research. As we come to learn more about the physical and chemical properties of substances (e.g. electrical conductivity, magnetism, optical properties, chemical reactivity, and the variations of these with pressure and temperature) we find that a full understanding of most of them necessitates measurements made on single crystals since these properties vary according to the crystallographic direction in which they are measured. A measurement on a polycrystalline sample thus gives an averaged value which is more difficult to interpret. Natural crystals (minerals) can sometimes be used, but are more likely to have grown under changing pressure, temperature and chemical environment than are crystals grown under controlled conditions in the laboratory.

Second, largely as a result of this single-crystal research, there is a rapidly growing demand for single crystals for industrial applications, some of which are listed in Table 1. This has resulted in large scale production of some crystals. During World War II one manufacturer was growing ammonium dihydrogen phosphate in lots of 31,360 crystals at a time. In forty days each of these reached a length of 9 inches with a cross-section about $1\frac{3}{4}$ inches square. They were then "harvested" and another lot was started from seed plates $\frac{1}{4}$ inch thick and $1\frac{3}{4}$ inches square. At the end of the war, the Linde Air Products Co. was producing nearly a thousand pounds of synthetic sapphire crystals a month, from which about two million jewels could be cut for bearings.

Techniques.—The goal of producing a large,

Table 1—SOME USES FOR WHICH SYNTHETIC CRYSTALS ARE GROWN

<i>Useful Property</i>	<i>Applications</i>	<i>Examples</i>
Piezoelectricity (electrical charge resulting from mechanical strain, and vice versa.)	Frequency control in radio communication. Detection of underwater sound. Phonograph pickups.	Quartz (SiO_2) "EDT" (ethylene diamine tartrate) "ADP" ($\text{NH}_4\text{H}_2\text{PO}_4$) Rochelle salt
Ferromagnetism (spontaneous magnetic polarization)	Memory devices (such as tape recorders) Coil cores	Iron, nickel, cobalt. The ferrites of iron, nickel, cobalt, etc
Ferroelectricity (spontaneous electric polarization)	Memory devices	Barium titanate (BaTiO_3)
Hardness	Jewels (watch bearings, etc.) Thread guides Phonograph needles Ball-point pens.	Ruby and sapphire (both Al_2O_3)
High index of refraction and dispersion of visible light (also hardness)	Gem-stones.	Ruby and sapphire, including star varieties. Rutile. Emerald
Transmission of ultra-violet and infra-red light.	Prisms and lenses for spectrometers.	Silver chloride (AgCl) Halite (sodium chloride, NaCl) Potassium bromide (KBr) Lithium fluoride (LiF)
Low electrical conductivity and chemical and physical stability	Electrical equipment.	Mica.
Semi-conductivity	Rectifiers. Transistor devices of all sorts.	Germanium. Silicon. Lead sulfide.
Bombardment-induced luminescence	Scintillation counters.	Anthracene Calcium tungstate.

perfect single crystal may be resolved into four parts: (1) to get a relatively small, perfect single crystal, or "seed"; (2) to cause additional atoms (or ions or molecules) to attach themselves to the seed at as rapid a rate as is consistent with their assuming a completely orderly arrangement continuous with that of the seed; (3) to avoid the inclusion of any "foreign matter," which refers not only to gas, liquid or solid of a composition other than that of the crystal, but to matter of the same composition, differently oriented or arranged; and (4) to avoid the formation of additional crystals which may use up material intended for the main crystal or crystals, or may become attached to them in a misoriented position.

A classified list of techniques that have been used for achieving crystal growth appears in Table 2. It can hardly be comprehensive since the various modifications of techniques are about as numerous as the individuals who use them.

The choice of a suitable technique depends on the properties of the substance to be grown. For example, if the substance melts at an attainable temperature without decomposition, excessive

Table 2. TECHNIQUES FOR GROWING CRYSTALS

- A. From a melt of the substance to be crystallized
 1. Obreimov—Schubnikov—Bridgman Stockbarger technique.
 2. Czochralski—Kyropoulos technique.
 3. Zone melting techniques.
 4. Verneuil method or flame-fusion technique.
- B. From a melt with the aid of fluxes, non-aqueous solution

Examples: The growth of barium titanate, diamond (?)
- C. From very hot aqueous solutions Hydrothermal techniques.

Examples: The growth of quartz, mica, tourmaline, beryl.
- D. From solutions at moderate temperatures.
 1. At constant temperature
 - a. By decreasing the amount of solvent by evaporation.
 - b. By increasing the amount of solute
 2. By varying the temperature to decrease solubility.

Examples: The growth of Rochelle salt, ADP, EDT (See Table 1)
- E. From the vapor state.
- F. By chemical decomposition.

Example: Koref hot-wire technique.

evaporation, or reaction with the container or the atmosphere provided for it, then it may be possible to crystallize it directly from a melt purely of its own composition. Even if it meets all the above requirements, but undergoes a destructive structural transformation or phase change between the temperature of solidification and cooling, the pure fusion technique will be unsuitable.

Addition of suitable fluxes may markedly lower the melting point, but, introduce the danger of contamination of the crystal produced. Even water molecules may act as contaminants in crystals grown from aqueous solutions. It is well known that large clear sodium chloride crystals may be grown from fused sodium chloride whereas those grown from aqueous solutions of sodium chloride are clouded with many fine fractures. One explanation offered for this difference is that water molecules included in the crystals cause structural distortion that ultimately results in fracture.

The following descriptions of the techniques listed in Table 2 are intended to acquaint the reader with the major features of each technique and not to serve as instructions for the process.

For these the reader must consult the original references, listed in the bibliographies which will be found in references at the end of this article

A. From a melt of the substance to be crystallized

1. In the *Obreimov—Schubnikov—Bridgman—Stockbarger technique* the melt is in a long narrow container whose bottom tapers to a point. Cooling is begun here with the hope that only one seed will be initiated. Its growth then proceeds as cooling is allowed to proceed slowly along the container. A steep temperature gradient is desirable to prevent formation of unwanted seeds.
2. In the *Czochralski—Kyropoulos technique* a seed crystal is gradually withdrawn from the surface of the melt with which it remains in contact due to growth.
3. *Zone-melting* is a technique which has been used for purification or for distributing desired impurities in special ways in a crystal. It is the process of moving a short molten zone or zones through a relatively long solid mass. It makes use of the difference in distribution of the impurities, wanted or unwanted, in the solid and in the liquid.
4. In the ingenious *Verneuil method*, originated by A. Verneuil at the end of the 19th century for the growth of Al_2O_3 gems (chiefly ruby and sapphire), the finely powdered source material is fed into the oxygen stream of an oxy-hydrogen blow torch directed downward toward the support on which the crystal is to be grown. The support is withdrawn as the crystal "boule" grows. The diameter of the boule is governed by the supply of oxygen and is made very small at some early stage of growth, as to achieve a single crystal seed. The sapphires and rubies grown by this technique can be distinguished from those grown in nature by microscopic examination since in the natural stones the distribution of minute inclusions tends to be planar, parallel to planar layers of atoms whereas, in the synthetic crystals the inclusions lie parallel to the curved surfaces of the boule.

Star sapphires and rubies are made by the addition of small amounts of an impurity which forms sub-microscopic inclusions in the crystal. Heat treatment subsequent to growth is commonly part of the process. These inclusions are oriented along six crystallographically equivalent directions in the crystal which, when properly cut and polished, shows a "star" of scattered light.

B. From a melt with the aid of fluxes. The melting point of a substance may be lowered by the presence of other substances, sometimes called fluxes. The resulting liquid mixture is properly termed a solution. An example of crystal growth from such a solution is that of barium titanate. The finely powdered material is thoroughly dissolved in molten potassium fluoride (KF) in a platinum crucible which is then slowly cooled. The resulting platy crystals of barium titanate are readily separated from the finally solid potassium fluoride because the latter is water soluble whereas the barium titanate is not.

Synthetic diamonds have been reported several times, but attempts to repeat the experiments described have not met with success. There is thus at present no known method for the reliable production of diamonds. Greatest credence is accorded to the account by J. B. Hannay. Hannay placed a mixture of rectified bone oil and "paraffin spirit" with some metallic lithium in a sealed container which he heated to dull red heat for 14 hours, then cooled slowly. He reported the formation of diamonds and the crystals in the British Museum which are labelled as the results of his experiments have been proven to be diamonds, but his experiments have been carefully repeated with no success.

On the basis of thermodynamics it has been shown that the diamond is stable only at high temperatures and pressures. Its persistence outside of its thermodynamic stability range is due to the structural stability of the strong carbon-carbon bonding in the diamond structure (See article on *Chemical Crystallography*). This does not mean that there is no chance of growing the diamond at moderate temperatures and pressures since a metastable state occurs spontaneously in many chemical processes.

C. From hot aqueous solutions. Many of the largest and best natural crystals are believed to have grown from hot aqueous solutions, probably containing potassium, aluminum, silica and carbon dioxide and probably under more than atmospheric pressure. Similar conditions can be created in the laboratory in sealed steel containers called autoclaves. An example of this technique of hydrothermal synthesis is the growth of quartz. In one method fragments of quartz are put in the bottom of a silver-lined autoclave and one or more seed crystals are suspended above from a silvered frame. The autoclave is then nearly filled with a dilute alkaline solution, sealed and heated at the bottom to about 400°C. for several weeks.

The suspended crystals in the cooler part of the container grow at the expense of the broken source material in the bottom.

D. *From solutions at moderate temperatures.* In the following discussion all the examples are crystals grown from water solutions, but it should be understood that the techniques are applicable to crystallization from other solvents where these are appropriate.

1. *At constant temperature:* (a) Anyone can grow small sodium chloride crystals from a salt solution in an open vessel by allowing the water to evaporate. This technique of crystal growth is often used to get a small perfect seed of a water soluble crystal for use in later, better controlled techniques. (b) The alternative constant temperature technique is to add solute at a rate commensurate with its removal from solution by crystal growth. In an apparatus using this technique four 43-pound ADP crystals were grown in a period of four months.
2. *By varying the temperature to decrease solubility.* Most water-soluble substances become less so with decreasing temperature; a few become more so. By appropriately varying the temperature of the

prerequisite may be obtained either by the Crochalski technique or by annealing a suitably cold-worked wire. Vaporized tungsten chloride (WCl_6) and hydrogen are passed over the wire which is heated by an electric current to about 1000°C . The heat from the wire causes the gases to react with each other producing tungsten which adds to the girth of the wire and hydrogen chloride which is carried away as a gas. Since the resistance of the wire decreases as its diameter increases, the current through the wire must be increased to keep it hot as it grows. The maximum obtainable current places a limitation on this process.

Theory.—A discussion of the theory of crystal growth is beyond the scope of this article. Although the subject has been an attractive one for growers of synthetic crystals, chemists and physicists, from Willard Gibbs' thermodynamic attack on it to the Burton, Cabrera and Frank school of the present day, full understanding has not yet been achieved. Verma's beautifully illustrated little book is recommended to those interested in the present theory of growth by spiral dislocations. In spite of the recently accelerated progress in theory and experiment, the art of growing large crystals is still in that state of incomplete understanding which makes each new problem one to be solved, not alone by knowledge of the prior art, but with the aid of ingenuity and imagination.

saturated solution the solute may be deposited on a seed crystal. A crystallizer using this technique, devised by A. N. Holden, is shown in Fig. 1. During the lowering of the temperature the seed crystals, fixed to the arms of a rotating spider, are swept through the solution, first clockwise, then counter-clockwise, ensuring a fresh supply of solute for the crystal growth and avoiding the concentration furrows and irregular shape of crystals that grow with no motion relative to the solution. There is double protection against unwanted seeds. Evaporating water condenses on the cool metal lid and drips back onto the surface, thus preventing seeding which might otherwise occur there and any seeds that do form in the container are swept to the center of the bottom by the vortex motion. Here a small, low-power heater, warming just this region of the solution, causes them to be redissolved.

E. *From the vapor state.* Crystals grown by direct crystallization from the vapor state have, for the most part, been very small. They are commonly needlelike.

F. *By chemical decomposition.* Koref's hot wire technique is an example of crystal growth by chemical decomposition. The single-crystal tungsten wire which is a

CSABA, chō'bō, or **BEKESCSABA**, bā'kash-chō-bō, city, Hungary, in, but independent of, Bekes County; 53 miles northeast of Szeged. An agricultural and marketing center, its manufactures include textiles, furniture, machines, shoes, and boxes. The city lost much of its surrounding area in 1950. Pop. (1941) 52,404.

CSONGRAD, chōng'grād, city, Hungary, a market town, capital of a county of the same name, at the junction of the Körö with the Tisza, 72 miles southeast of Budapest. The surrounding country is very flat and has excellent pastures. The chief occupations are cattle-raising, agriculture, wine-making and fishing. Pop. (1941) 25,594.

CTENOID, tē'noid (Gr. "comblike"), applied to the scales of fishes when jagged or pectinated on the edge like the teeth of a comb, as in the perch, flounder and turbot.

CTENOPHORA, tē-nōf'ō-rā, a phylum of animals, sometimes grouped under the Coelenterata (q.v.), but distinguished from them by the absence of stinging cells and the presence of a third germinal layer. They also possess comb-like bands of cilia which serve them for

locomotion. Being very abundant, marine, jelly-fishlike animals, they swim by means of eight meridional bands of transverse, comblike plates.

CTESIAS, tē'zī-ās, Greek physician and historian: fl. 5th century B.C. In 415 B.C. he was captured by the Persians and lived for 17 years as a physician at the court of Artaxerxes Mnemon of Persia. It was here that he wrote, among other works, the *Persica*. According to Diodorus, this work of Ctesias was derived from the Persian royal archives and was intended to discredit the history of Herodotus. All that remains of the history of Ctesias is an abridgment in the writings of Photius and the fragments that are contained in the works of Diodorus, Plutarch, and other historians.

CTESIBIUS, tē-sīb'ī-ūs, Greek physicist and inventor: fl. 2d century B.C. He lived at Alexandria and, with the influence of Ptolemy II (Ptolemy Philadelphus) and Ptolemy III (Ptolemy Euergetes), became famous for his mechanical inventions. With his pupil Hero of Alexandria, Ctesibius is credited with the discovery of the expansive power of air and its application as a motive power. Specific inventions included the force pump, water clock, bent syphon, and fire engine.

CTESIPHON, tēs'ī-fōn, Greek orator: fl. 4th century B.C. He was a citizen of Athens and was prosecuted by Aeschines for a proposal that Demosthenes be given a gold crown for his distinguished work. He was defended by Demosthenes, and their orations for this occasion, referred to as *On the Crown*, are praised as two of the great Greek orations.

CTESIPHON, tēs'ī-fōn, ancient ruined city in Iraq, on the east bank of the Tigris opposite Seleucia and 20 miles south-southeast of Baghdad. It was the capital of the ancient kingdom of Parthia and of the later Sassanid empire. There are ruins of a magnificent vaulted hall of the Sassanid period. Ctesiphon was captured by the Romans in 115 A.D. and by the Arabs in 637 A.D. After Baghdad became the capital of the Abbassid caliphate in the 8th century the city became deserted. On Nov. 21, 1915, during World War I, British forces under Gen. Charles Townshend were defeated here by the Turks and compelled to retreat to Kut-al-Imara (Kut-el-Amara).

CUANZA or **KWANZA**, kwān'zā, river in Angola, southwest Africa, rising in the south central part of that Portuguese colony and flowing in a northwesterly direction to enter the Atlantic Ocean just south of Luanda (São Paulo de Loanda). The length is about 500 miles. It is navigable for small vessels until falls are reached 160 miles from its mouth.

CUAUTLA, kwou'tlā, town, Mexico, in the state of Morelos 18 miles southeast of Cuernavaca. It is a popular resort because of its hot sulphur springs; they were frequented by the Indians even before the Spanish conquest. Here, during the revolution in 1812, José María Morelos y Pavón, Mexican priest and patriot, withstood for three months a siege by royalist forces under Félix María Calleja del Rey. A century later the town was the center of the revolutionary

activities of Emiliano Zapata. Pop. (1940) 6,431

CUBA, a republic and largest island of the West Indies. Its western end projects into the Gulf of Mexico and is separated from the United States by the Florida Strait and from Mexico by the Yucatán Channel. The eastern end is also separated by channels from the Bahamas to the north, and Jamaica to the south, while to the east the island is separated from Haiti by the Windward Passage. It lies just below the Tropic of Cancer, within longitudes 74° 2' and 84° 59' west of Greenwich and between 19° 48' and 23° 12' north latitude. This privileged strategic position, dominating the three sea lanes between the Atlantic, the Gulf of Mexico, and the Caribbean, gave Cuba the name of "the Key to the New World." The main island, narrow and arching northward to a point only 90 miles from Key West, Fla., is 760 miles long. Its width averages 60 miles, ranging between 25 and 124 miles. Its total area including the Isle of Pines and other adjacent small islands is 44,164 square miles, or about the size of Pennsylvania, and its population (1943) was 4,778,583. Havana (Span. Habana, pop. 676,376) is the capital city. The monetary unit is the peso, on a par with the U.S. dollar, and the metric system of weights and measures is used. The flag of Cuba is formed by a lone star in a red triangle, from two sides of which flow five alternately blue and white horizontal stripes. The national anthem is the *Himno Bayamés*.

The Land.—About one half of Cuba consists of flat or rolling terrain, while the remainder is hilly or mountainous. There are three distinct groups of mountains. In the westernmost province, Pinar del Río, the Sierra de los Organos extends from Cape San Antonio to the boundary line of Havana Province, reaching a height of 1,800 feet. The range extends eastward along the north coast of the four central provinces in the form of lower, disconnected hills. In the extreme eastern end of the island, it forms the impressive landscape around Baracoa and Sagua de Tánamo, famous for its natural wonders. Southeast of Baracoa the range reaches an altitude of 4,020 feet. The Guamuhaya Range occupies a limited area in the southern part of Las Villas (formerly Santa Clara) Province, between Cienfuegos and Trinidad. Its highest summit is 3,792 feet above sea level. The third mountain system is that of the Sierra Maestra extending eastward from Cape Cruz along the southern coast of Oriente Province and including the Sierra del Cobre and Macaca ranges. Rising precipitously from the Caribbean Sea, these rugged and majestic mountains hem in the landlocked harbors of Santiago de Cuba and Guantánamo. Pico Turquino (7,870 feet) in the Sierra Maestra is the highest elevation on the island. Thus all of the northern coastal regions and the

southern coast as far west as Cape Cruz are mountainous or hilly. Between these ranges are a number of extremely fertile plateaus and valleys. A long stretch of coast on the Caribbean Sea, especially the southern part of Las Villas and Matanzas provinces, is comparatively low-lying and swampy. South of Matanzas lies the great Zapata swamp.

Sixty miles off Batabanó on the southwestern coast is the Isle of Pines (1,180 square miles), once claimed by the United States but relinquished to Cuba by the treaty of March 13, 1925.

All parts of Cuba are within comparatively easy reach of the coast. Numerous good harbors are evenly distributed along the northern coast and the mountainous sections of the southern shoreline. The rivers are for the most part too short and too rapid for navigation. The longest is the Río Cauto, in Oriente Province, which runs 150 miles westward into the Gulf of Guacanayabo, and is navigable for one third of its length. A number of the streams disappear into subterranean channels cut through white limestone.

The climate is semitropical. Temperatures are slightly higher at the eastern end of Cuba than at the western extremity, but due to prevailing winds and the east-west axis of the island, the climate is moderate and relatively uniform. There are two distinct seasons. From May to October is warm and rainy, while the cool, dry season extends from November to April. The average yearly rainfall is 50 inches on the northern coast, 45 on the southern coast, and 60 in the interior. The temperature ranges between extremes of 60° and 98° F. The annual average temperature at Havana is 77°.

Political Divisions, Chief Cities, Population.—Corresponding to tradition and geographical lines, Cuba is divided politically into six provinces as follows:

	Area in square miles	Population 1943	Population per square mile
Pinar del Río.....	5,206	398,794	76.6
Havana (Habana).....	3,170	1,235,939	309.9
Matanzas.....	3,256	361,079	110.9
Las Villas.....	8,257	938,581	113.6
Camagüey.....	10,064	487,701	48.5
Oriente.....	14,211	1,356,489	95.5
	44,164	4,778,583	108.2

The basic political unit of the country, however, is the municipality. The following table lists the cities with over 100,000 population:

City	Province	Population 1943
Havana *	Havana	676,376
Holguín.....	Oriente	171,997
Camagüey *	Camagüey	155,827
Marianao.....	Havana	135,815
Santa Clara *	Las Villas	122,241
Santiago de Cuba *	Oriente	120,577
Sancti Spiritus.....	Las Villas	104,578

* Capital of the province.

Havana, also the capital of the nation, is the principal seaport and the economic and cultural heart of the country, as well as, by far, the largest city. Including suburbs, its population exceeds 800,000.

The total population of Cuba has risen steadily since early colonial times, except for the brief period during the war of independence, as demonstrated by the following table:

1774.....	171,620	1919.....	2,889,004
1827.....	704,487	1931.....	3,962,344
1877.....	1,631,687	1943.....	4,778,583
1899.....	1,572,797		

However, the average yearly increase in population between 1931-1943 amounted only to 1.7 per cent whereas from 1919-1931 it was 3.1 per cent. This marked decline can be readily accounted for by government restrictions on immigration after 1931. A slight decrease in the birth rate was also registered, but this can be attributed to the economic and political crisis which marked the early part of that period, rather than as a permanent trend. Taking the above factors into consideration, a continued increase in the population may be expected in the near future, though at a much lower rate than in the past, unless immigration restrictions are lifted.

In 1943 the population was divided into 54.5 per cent urban and 45.5 per cent rural, showing an increase of 3.2 per cent over 1931 in the urban population with respect to the rural. This was due both to an increase in the number of urban centers and to a greater concentration of population in the larger cities. The trend will probably continue in view of the increasing industrialization. See also separate articles on chief cities.

The People.—According to the 1943 census figures, the population of Cuba is divided approximately into 70 per cent white and 30 per cent colored or of mixed blood. This shows an increase in the proportion of whites since the establishment of independence in 1902. According to the census taken in 1899 during the United States occupation, the proportion was 60 per cent white and 40 per cent colored. The increase is fully accounted for by white immigration in the intervening years.

During the first 30 years of the republic (1902-1932) 1,261,788 immigrants entered Cuba, of whom 760,000 were Spaniards, 189,866 Haitians, 120,989 Jamaicans, and 33,602 United States citizens. Most of the latter were transients, and in 1943 less than 10,000 were residing in Cuba. The colored immigrants represented by the Haitians and Jamaicans were, in great part, workers contracted each year for the sugar harvest, and required to return to their countries at the harvest's end. In 1933 and 1934 the Cuban government rounded up and repatriated most of those who had illegally remained. There was thus a surplus of white immigration exceeding 600,000.

The proportion of the white and colored population in the past has also depended on the character of immigration. White immigration began in 1511 with the conquest and settlement of the island by Spain. The importation of Negro slaves from Africa followed soon after because of the rapid extinction of the native Indians and Spain's prohibition to enslave those who remained. In the 16th and 17th centuries both white and colored immigration was limited by Spanish colonial policy, the total population increasing very slowly. But during the latter part of the 18th century and the beginning of the 19th, owing to the expansion of the sugar industry, the slave trade received a great impetus. As a result, the total Negro population, both slave and free, rose to outnumber the white for a short period. With the abolition of slave trade and succeeding waves of Spanish immigration, before as well as after independence, the trend was reversed and the proportion of whites rose steadily.

Assuming immigration restrictions are maintained, no marked changes may be expected in the near future as to the proportion of whites and Negroes.

During the critical years of 1933-1937 not only was there a stoppage of immigration but a net outward balance of 54,090 was registered. With the return of normal conditions, however, this emigrant movement has been checked.

The vast majority of the white population is of Spanish descent or of Spanish birth. The latter class will, of course, disappear in time unless there is new immigration. The Cuban-born children of Spaniards are immediately assimilated and are indistinguishable from other white Cubans. Among the colored population there is a small segment of Chinese and some traces of the aboriginal Indians.

The language of the country is Spanish and the culture is essentially Spanish, though naturally they have both undergone some change upon being transplanted to the Western Hemisphere, similar to that undergone by the English language and culture in the United States. The Negroes, in particular, have contributed a characteristic emotional influence largely revealed in music. The colored race has also produced several fine poets and plastic artists. Antonio Maceo, one of the great leaders of the War of Independence, was a mulatto.

The relations between the races are particularly happy in Cuba. There are no legal or political discriminations of any kind. Though social prejudice against Negroes undoubtedly exists, it is not manifested by any public measures, nor does it prevent recognition of personal ability. The existence of a large mulatto population, outnumbering the full-blooded Negroes and tending to increase, points to continual miscegenation, but this does not seem to present any very serious problem. All in all, Cuba is an outstanding example of racial democracy.

Natural Resources.—Minerals.—The Cuban subsoil is rich in minerals, still only partly exploited, although during World War II mining activities were greatly stimulated owing to United States war production demand. The most important minerals from the viewpoint of development and export are manganese, copper, iron, chromium, nickel, and asphalt. Other minerals include gold, silver, mercury, zinc, lead, barium, antimony, sulphur, coal, asbestos, marble, and petroleum.

Cuba ranks fourth in the world in iron ore deposits, but only 20th with respect to extraction. Of the more than three billion tons estimated to exist, one United States company owns the rights to 90 per cent, reducing extraction operations to a minimum and holding the rest as a reserve for the future. The deposits are located in the Moa Sierra, Oriente Province. In manganese production Cuba ranks second to Brazil in the Western Hemisphere.

There are conflicting opinions with respect to the existence of deep oil deposits in Cuba. Reports of petroleum companies during 1945 were more promising than in previous years. Up to 1946 surface deposits of light gravity oil had been discovered in the Jarahuca district and naphtha, or natural gasoline, in the Motembo area in Matanzas and Las Villas. In 1945 light gravity oil, produced by numerous small companies, totaled 4,000,000 gallons, compared with approximately 600,000 gallons during the previous year. Production of naphtha declined in the Motembo area from 4,000,000 gallons in 1944 to 2,350,000 in 1945.

Production of copper and refractory chromite

in 1945 maintained its high wartime rate, while the large United States sponsored nickel oxide plant in Lengua de Pájaro, Oriente, in that same year, reached its full production capacity. Manganese and metallurgical chromite production, however, declined sharply when the United States government procurement program terminated with the war's end. The Cuban American Manganese Corporation and the Nicaro Nickel Company, both subsidiaries of the Freeport Sulphur Corporation, practically put an end to their activities in 1946. On the other hand, as a result of the discovery of additional copper ore reserves, production of copper concentrates increased. Output in 1945 amounted to 26,610 long tons. Compared with 21,830 in 1944. Practically all the ore goes to the United States.

Forests.—Although much valuable forest land was destroyed to make way for the expanding sugar industry, about one tenth of Cuba's area is still covered by forest. There are many hardwoods, chief of which are mahogany, cedar, ebony, *lignum vitae*, and *majagua*. Mahogany is exported, cedar is used for cigar boxes and pencils; both are also used for cabinetwork. The total value of forest products in 1944 was put at \$5,800,000.

Fisheries.—The value of fishing products in 1944 was estimated at \$6,000,000. Edible fish products are almost all domestically consumed. Batabanó, on the southern coast of Havana Province, is the center of one of the largest sponge industries in the world. Sponge exports in 1945 were valued at \$548,233.

Agriculture.—Of the total employed persons in Cuba in 1943, 41.1 per cent were engaged in agriculture, cattle raising, and fishing, which compares with 18.8 per cent in the United States, showing clearly the vital importance of these activities in the national economy. The cultivation of sugarcane constitutes the basis of the whole Cuban economic structure. But it is so inextricably bound up with the industrial process of the extraction of sugar and its derivatives and is involved with so many complex social and political factors, that it is dealt with in the separate section *Sugar Industry*.

To combat the evils of a one-crop economy, the Cuban government has actively encouraged the diversification of agriculture. The valleys and plains of Cuba possess extremely fertile soils which, due to the equable climate, yield crops the year round. Next to sugarcane, though far below it in value, the chief agricultural products in order of their importance are: tobacco, fruits and vegetables, coffee, henequen fiber (used mainly for rope), and corn (for domestic consumption only). Cacao, rice, honey, beeswax, and cotton are also produced.

Tobacco.—The tobacco plant is indigenous to Cuba; its use was known to the Indians before the Spanish discovery. The highest grade tobacco, known the world over as pure Havana, is grown in the Vuelta Abajo district of Pinar del Río Province, in a relatively small zone near San Juan y Martínez. It is sold both internally and to foreign markets, either in the leaf or, after a manufacturing process, as finished tobaccos, cigarettes, and cigarette fillings. In 1945 the tobacco crop amounted to 67 million pounds and was further expanded in 1946. Domestic consumption absorbs about 40 per cent. The total value of tobacco and tobacco products exported in 1945 amounted to \$50,400,000; 56 per cent of

the crop was sold to the United States. World War II brought big reductions in the British and Spanish markets, and Argentina took Spain's place as the second largest importer.

Fruits and Vegetables.—Aside from the citrus fruits and well-known tropical fruits such as bananas, pineapples and avocados, there are many others not suitable for export which are consumed domestically, among them mangoes, mammee and sweetsop. Practically all vegetables grown in temperate climates are also grown in Cuba. The year 1945 was a bad one for agricultural exports owing to severe drought and shipping difficulties. Nevertheless, about 60 million pounds of fresh pineapples, valued at \$2,000,000, and approximately 2,300,000 bunches of bananas, valued at \$1,700,000, were sold to the United States. A considerable amount of vegetables are exported during the winter months to the United States.

Coffee.—The production, distribution, and sale of coffee is controlled by the Stabilization Institute. About 30 per cent of the crop is segregated for export and minimum prices are fixed for the domestic market. In 1944, 76,850,000 pounds were produced.

Henequen.—Production of henequen fiber amounted to about 29,000,000 pounds. The value of the fiber crop was about \$2,600,000, and rope exports to the United States yielded approximately an equal sum.

Cattle Raising.—One of the chief industries in Cuba during early colonial times was cattle raising. With the expansion of the sugar industry, it diminished in importance, but after the collapse of the sugar boom it experienced a revival. From a beef importing country, Cuba again became an exporter. Camagüey Province, owing to its wide, rolling pasture land has always been the chief cattle-raising center. By 1945 the number of head of cattle had increased to nearly 6,000,000 due to favorable climatic conditions and the absence of pests. The government and the ranchers have taken active scientific measures to improve the breeds. Raw hides and skins constitute more than half of Cuba's pastoral exports. Horses, mules, pigs, and sheep are also raised. The dairying industry has grown steadily, producing cheeses, butter, and condensed milk.

Sugar Industry.—Despite its small size, Cuba is the world's greatest supplier of sugar, accounting for one fourth of the total entering international trade. India, the only country producing more, consumes almost its entire output. During favorable years the value of Cuba's sugar crop and its derivatives—molasses and syrups—averaged roughly around \$300,000,000 which represented over three fourths of the country's total exports. Of the cultivated land, 57 per cent is devoted to sugarcane, and during the four months of the harvest about 500,000 field workers are employed. It is more than evident that the sugar industry is the backbone of Cuba's national economy. This extraordinary development has been made possible by the remarkable fertility of the soil, which yields five or six crops without replanting; also the proximity of the United States market. As more than 80 per cent of the sugar crop normally has been sold to the United States, Cuba's prosperity, as long as it depends on sugar, will be contingent upon the demand in the United States. In 1947, as a result of the raising of the United States quota following the war's end, Cuba's sugar production reached an all-time high

of 6,448,328 tons, but prices were considerably below those obtaining during the great boom after World War I.

Sugar was first cultivated in Cuba late in the 16th century, but it was not until the end of the 18th century, when sugar crystallization was developed, that the industry began to expand, additional labor being supplied by the slave trade. A number of landed Cuban families acquired considerable wealth and more Spaniards arrived to exploit this new source of riches. The sugar mills were rudimentary, but slave labor kept production costs low. It was a patriarchal system, resembling that of the pre-Civil War southern plantations of the United States. The long struggle for Cuban independence wrought great havoc. A scorched earth policy was adopted by the revolutionary forces and resulted in wholesale destruction of crops and mills. Following the Spanish American War and the establishment of the republic (1902), the United States granted Cuba preferential tariff treatment. Foreign capital began to pour in and sugar became a big business. World War I accelerated the process. After the war's end, the price of sugar soared to over 20 cents per pound. Great corporations were formed, most of them controlled by United States capital. Cubans sold their mills and land for fabulous sums. It was "the dance of the millions." When the bubble burst it developed that Cubans no longer owned their sugar industry. Meanwhile, the foreign sugar companies, accorded extraordinary privileges because they now controlled Cuban economy, were the new colonizers, but without the responsibilities of government. The tendency toward concentration and centralization of production rapidly increased. Mammoth mills were installed and managed with a maximum of efficiency. Production rose from 1,000,000 tons in 1895 to over 5,000,000 in 1925. The workers were often paid in scrip which they could use only in the company stores. Haitian and Jamaican laborers were imported for the sugar harvest to the detriment of Cuban workers. Nevertheless, beet sugar, protected by high tariffs, competed favorably with Cuban sugar in the world markets and Java, with lower production costs, refused to subscribe to international agreements regulating production. As most of Cuba's other sources of wealth had been woefully neglected as a result of the "dance of the millions," the world depression hit Cuba particularly hard. The price of sugar fell to a fraction of a cent per pound and production dropped to less than 2,000,000 tons in 1932. Cuba's economy, geared to the sugar industry, was at the mercy of the international market. The sugar companies fared badly, and a relatively few United States and Canadian banks came to control a large part of the sugar properties. The result for Cuba was political revolution and the birth of a new national conscience which demanded not solely political but also economic independence. After the overthrow of President Gerardo Machado in 1933, the revolutionary governments adopted vigorous measures. The law prohibiting payment to workers in scrip was enforced. Haitian and Jamaican laborers who had illegally remained were repatriated. An eight-hour labor law was passed. The Association of *colonos*, or sugarcane growers, as distinct from the sugar mill owners, was formed in 1934 to protect their interests. The *colonos* constituted that part of

the sugar industry which had remained firmly in Cuban hands. The big sugar companies had two sources of sugarcane. One was the cane they grew and harvested on their own land, called administration cane. The other was the cane obtained from nearby plantations whose Cuban owners, or *colonos*, contracted with the mills to furnish them a quantity of cane in return for a corresponding amount of sugar ground by the mill. The smaller plantations (*colonias*) were particularly at the mercy of the mills. The Law of Sugar Coordination of 1937 fixed the proportion of sugar which the *colono* must receive for his cane and otherwise protected him. This was all the more effective as the new labor laws and minimum wages had forced the sugar companies to give up much of their administration cane and fall back on the *colonos* for their supplies of the raw product.

In 1930 the Cuban government created a Sugar Stabilization Institute, authorized to fix production quotas, control exports, and participate in international agreements. The Cubans who still retained a share in the sugar industry began playing a more active part through the Cuban National Association of Sugar Mill Owners.

But the sugar industry was no longer free. It had become, in fact, one of the most highly controlled industries in the world. This had been the outcome of the establishment of quota systems by consuming countries, principally the United States. Under the Jones-Costigan Act of 1934 the United States fixed sugar imports from Cuba at roughly 30 per cent of internal consumption. Although the tariff rate was lowered, a processing tax of one-half cent per pound was imposed on all Cuban sugar entering the United States, earmarked for the maintenance of the United States beet sugar industry. This measure, in effect, forced the Cuban sugar industry to subsidize the further development of United States beet sugar, its greatest competitor.

As a result of this system, Cuban sugar production must be fixed each year in accordance with the quota established by the United States. This is done by an annual decree of the Cuban president which also establishes individual quotas for each mill. In view of these restrictions on production, the big corporations and the banks began selling part of their properties back to the Cubans. In 1939, of 156 active sugar mills, 55 were owned by Cubans; 59, by United States interests; 28, by Spanish firms; and the balance, by Canadians and others. However, the United States mills, with greater capacities, controlled 55 per cent of the total production, while the Cubans controlled only 34 per cent. The trend toward a return to Cuban ownership continued during the following years. In 1946, Cubans owned 102 mills; the United States, 49; Spaniards and Canadians, 5 each; and all other foreign owners had disappeared. The United States mills then had only a slight edge on the production total.

During World War II great emphasis was placed on the derivative products obtained in the processing of sugar. Black strap molasses, in particular, found a profitable market in the United States as a source of industrial alcohol for war production. Many sugar mills also went into the distillery and liquor business as sidelines.

The two greatest enemies facing the sugar industry in the future are world overproduction

or, according to some, underconsumption, and the possible development of synthetic sugar substitutes. In preparation for such eventualities research work is being carried on to determine what other byproducts may be obtained from sugarcane which could find a world market. There seem to be possibilities in the field of plastics.

Manufacturing Industries.—Spanish policy prevented the growth of manufacturing industry in colonial times. After independence, and especially following the collapse of the sugar market in the late 1920's, the Cuban government inaugurated a policy of tariff protection which resulted in new manufacturing activities. This policy was continued and in 1945 the government issued several decrees providing for the duty-free entry of machinery and other industrial equipment, and granting broad tax exemptions to new industries.

In general, aside from sugar and tobacco products, manufacturing industries produce for internal consumption only. Industries using domestic raw materials include: the manufacture of cigars and cigarettes, rope and twine, jerked beef, dairy products, canned fruit, rum, furniture, cement, brick, and tile. Manufactures based on imported raw materials include: soap, perfumes, toilet preparations, beer, paint, wax matches, clothing, shoes, hats, paper, cardboard, ink, tin containers, glassware, and aluminum ware. Of the cotton textile used, 40 per cent is locally produced. The total number of workers employed in all manufacturing and mechanical industries in 1943 was 187,645.

Labor Relations.—Labor relations in Cuba are governed by constitutional precepts and advanced labor laws. Cuban labor is highly organized. Approximately 33 per cent of Cuban workers were unionized in 1946, the highest total of any Latin American country. The different unions together form the Confederación de Trabajadores de Cuba, or CTC (Confederation of Cuban Workers), which wields great influence in directing the labor movement. The Ministry of Labor is empowered to regulate and supervise the application of the labor laws, and acts as a conciliatory body in conflicts between management and labor. It also helps establish the basis for minimum wages. In 1945, the CTC announced itself in favor of the mechanization of the sugar and tobacco industries, which it had long opposed.

Trade.—Foreign Commerce.—Cuba has the third largest per capita foreign trade in the Western Hemisphere, following Canada and Argentina, and since 1904 has always had a favorable trade balance. In the last normal year before the outbreak of World War II, the country ranked fifth in foreign trade among Latin American countries: exports represented 8 per cent of the total value of exports of the 20 Latin American nations, and imports constituted 7 per cent of total Latin American imports.

DISTRIBUTION OF CUBAN FOREIGN TRADE IN PERCENTAGES

	Exports		Imports

The United States plays the leading role in Cuba's trade relations. It furnishes and absorbs between 70 and 80 per cent of all imports and

exports. Previous to World War II, the United Kingdom, other European countries, and some Asiatic countries supplied and purchased most of the other 20 to 30 per cent. But when the majority of these markets were closed to Cuba as a consequence of the war, the result was an increased percentage of trade with Latin America. All indications are that this trade trend, although a war-stimulated condition, will continue during peacetime.

CUBAN FOREIGN TRADE
(in thousands of U. S. dollars)

Sugar is Cuba's outstanding export, and with its derivatives constitutes approximately 75 per cent of all exports. However, the percentage has at times been larger. Over the period between 1919 and 1930, sugar and its derivatives averaged 86 per cent of exports; tobacco and its products averaged 10.3 per cent; other products, such as minerals, livestock, and lumber, 3.7 per cent. In the period 1931-1941, sugar and its derivatives declined to 77.7 per cent; tobacco and its products remained approximately the same with 10.8 per cent; while other products, which included a higher proportion of food and minerals, rose to 11.5 per cent. This seems to indicate that the country has made some progress in its efforts to work away from a one-crop economy.

In the last prewar year, 1938, foods and beverages made up almost 30 per cent of all imports. The following groups constituted approximately 10 per cent each: machines, instruments, and vehicles; pharmaceuticals and chemicals; cotton and its manufactured products; minerals, glass, and ceramics; and metals and its manufactures. In 1945 the total value of imports more than doubled, owing in great part to higher prices, but the proportion of the different imports remained approximately the same.

Internal Trade.—Internal trade plays a very important role in Cuba's economy following agriculture and the sugar industry. One third of total employed persons are occupied in some form of commercial activity. In 1945 indicators, such as merchandise sales, construction, and electric power consumption revealed a higher degree of activity than in the previous year and very much higher than in 1938, the last prewar year. Total deposits in banks and the per capita circulation of money increased 300 per cent during the World War II years, indicating a very definite material improvement in the general welfare of the people. This was due to the fact that the large increase in the country's income after the outbreak of World War II was more equally distributed than in other prosperous periods, such as that which followed World War I. Wholesale and retail sales, based on tax returns, totaled \$1,260,000,000 in 1945, compared with \$809,000,000 in 1941.

In 1945, for the first time since Pearl Harbor, the tourist trade revived somewhat, with 21,349 visitors, but was still far below the 1937 peak

of 178,496. The tourist trade is an important source of income to Cuba. In normal years these visitors leave an estimated \$12,338,000, an average of \$91.85 each.

Transportation and Communication.—**Highways.**—Between the two extreme points of the island, Santiago de Cuba and Pinar del Rio, runs the Central Highway which was built in 1929-1931 and extends 706 miles. Tributary roads connect it with the provincial capitals and other large cities. Aside from these, however, road surfaces are poor. In 1945, Cuba had 255 miles of improved highway and 2,140 miles of paved road, or one mile of road per 19 square miles of area. At the end of 1944 there were 23,750 passenger automobiles, 14,829 trucks, and 2,635 busses.

Railroads.—The railroad network in Cuba is relatively mature, with 4,880 miles of main line railway. The United Railways of Havana (British capital) operates 2,335 miles of this main line track, covering the western end of the island. The Consolidated Railways of Cuba (United States capital) controls 1,731 miles and services the eastern part of Cuba. There are other smaller lines and many private railways run by sugar companies. In 1944, railroads carried an estimated 10,000,000 passengers. The street railway systems in Havana and the major cities carried 150,000,000 passengers in 1944.

Shipping.—The only Cuban ship lines are the Isle of Pines Steamship Company and the Empresa Naviera which respectively maintain sailings from the mainland to the Isle of Pines, and between main island ports. Before World War II many foreign lines maintained regular and irregular sailings connecting Cuba with the rest of America and Europe. In normal years about 5,000 ships entered Cuban ports. Havana handles approximately 83 per cent of imports and 27 per cent of exports. Exports pass through many other ports because sugar, the principal commodity, is shipped by the mills from the nearest port. There is a free trade zone in Matanzas, but it has not been properly developed and so had not proved of much value.

Airlines.—The Cuban National Aviation Company, a subsidiary of Pan American Airways, operates within Cuba only. A Cuban company, Expreso Aéreo Interamericano, runs a freight express between Havana and Miami, and between Havana and the Isle of Pines. Pan American Airways operates daily flights connecting the island with North and South America. In 1945, many privately owned and operated airports (mostly by sugar mills) were opened to the public, thus augmenting greatly the number of airports. Civil aviation has made considerable progress. A Civil Aviation Committee has been formed which acts as an advisory board to the National Transportation Commission.

Communications.—The Cuban postal service, under the Ministry of Communications, charges 2 cents per ounce for all local first-class mail; 5 cents per half ounce for local airmail; and 10 cents per half ounce for international airmail. Cables and radiograms are handled by Western Union, the West Indies Cable and Wireless, All America Cables, Mackay Radio, Radio Corporation of America, and Cuban Transatlantic Radio. Government-owned telegraph and radio telegraph systems service the entire island. In 1942 there were 357 telegraph offices with 8,805 miles of wire. The only public telephone system is oper-

ated by the Cuban Telephone Company, a subsidiary of International Telephone and Telegraph Corporation. In 1945 there were 73,995 telephones throughout the country, of which more than 90 per cent were connected with automatic stations, and there was a great demand for additional facilities. There are 110 long- and short-wave radio broadcasting stations. In 1945 there were 226,000 radios in private use.

Radio.—The 110 long- and short-wave radio broadcasting stations in Cuba are privately owned and free of state control. The chief ones are the RHC Cadena Azul, or Blue Network, with stations in six cities, and the CMQ Station. The Ministry of Communications has a government broadcasting station which puts on cultural and informational programs. Radio broadcasting has an important place in Cuban life. It is estimated that almost \$6,000,000 is involved in this new industry, and no other medium of communication or entertainment reaches so wide an audience.

Economic and Financial Factors.—*Public Finance and Public Debt.*—Due to the enactment of new tax laws and the increase of business activity, Cuba's national revenue more than doubled between 1939 and 1945, and a \$5,000,000 budget deficit was turned into a substantial surplus. The tax structure has become very complex and includes taxes on personal income, business profits, excess profits, sales, bank deposits, property transfers, land, transport, and stamp and excise taxes.

	Revenues	Expenditures
1939.....	\$71,000,000	\$76,000,000
1944.....	162,600,000	145,800,000
1945.....	177,100,000	154,300,000

In addition to the regular budgetary expenditures in 1945, \$16,818,371 was spent under extra budgetary appropriations, largely for public works and hurricane relief, which still left a surplus of almost \$6,000,000.

Cuba's funded debt in 1944 aggregated \$108,500,000 and was reduced to \$102,700,000 as of Dec. 31, 1945. The total debt under the \$25,000,000 Export-Import Bank of Washington credit was \$8,384,375 as compared with \$815,000 in 1944. The floating debt, consisting of unpaid claims for goods and services on open account and variously estimated as between \$50,000,000 and \$90,000,000, was not reduced, but neither was it increased during 1945.

Banking System.—Although legislation for the creation of a national central bank had been pending in the Cuban Congress since 1941, no action on it was taken before the end of 1946. In 1944 banking was in the hands of 7 United States and Canadian banks and 37 Cuban-owned banks. Of the Cuban banks, however, only a few, such as the Banco del Comercio, Gelats and Company, and the Banco de Nuñez, are important; the others conduct very limited operations. The United States and Canadian banks include the National City Bank of New York, the Chase National Bank, the first National Bank of Boston, the Royal Bank of Canada, the Bank of Nova Scotia, and the Canadian Bank of Commerce. In 1944, Havana bank clearings totaled \$1,280,630,000, while total bank assets and liabilities aggregated \$419,573,031, representing an increase of about 43 per cent over 1943.

Foreign Capital Investments.—By far the greatest share of foreign investments in Cuba is held by United States capital which was esti-

mated in 1940 at \$559,837,000, distributed as follows:

Sugar industry and agriculture.....	\$240,871,000
Utilities and transport.....	233,421,000
Manufacturing	26,845,000
Distribution	11,874,000
Petroleum	10,195,000
Mining	6,636,000
Others	29,995,000
	\$559,837,000

Investments of British capital at the close of 1943 aggregated £26,943,905 mostly in railroads. There were also considerable Spanish and Canadian investments, of which the former have been greatly reduced due to the transfer of property to Cuban ownership.

Monetary System, Coinage, Weights and Measures.—The monetary unit of Cuba is the peso, which has a par value of one U. S. dollar. Cuban silver pesos and silver certificates, as well as United States currency, constitute legal tender. The peso is divided into 100 centavos. Silver coins of 40, 20, and 10 centavos and nickel coins of 5, 2, and 1 centavos are minted. As there is no bank of issue, all certificates and coins are issued under government authority. Cuban paper money is in denominations of 1, 5, 10, 20, and 50 pesos, redeemable in silver minted coin. By 1943, silver certificates amounting to 132,051,212 pesos had been issued, backed by 79,790,000 silver pesos, \$44,999,907 in gold bars, \$1,240,712 in gold coins, and \$5,000,182.02 in United States currency. In 1945 the Cuban gold reserve was increased by purchases of bullion against dollars, which were withdrawn from circulation and replaced with Cuban currency, thus increasing the proportion of Cuban currency to dollars in the Cuban monetary system.

The metric system is the legal standard in weights and measures in Cuba. Other weights and measures commonly used are: the vara, 33.38 inches; the cordel, 0.1023 acres; the caballeria, 33.162 acres; the quintal, 101.43 pounds; the Spanish short ton, 2,028.6 pounds; and the Spanish long ton, 2,272 pounds.

Government.—The Cuban Republic is democratic, centralized, and based on a written constitution. The original Constitution of 1901 was amended in 1928 and voided in 1933 after the overthrow of President Gerardo Machado. On Oct. 10, 1940 a new constitution was promulgated. It provides for a division of powers between the executive, legislative, and judicial branches; guarantees individual liberties; establishes secret, universal suffrage; expressly rejects any discrimination on grounds of sex, race, or religion; and stresses social objectives, giving certain powers to the state to intervene in industry, commerce, and agriculture in the interests of the public welfare. The new constitution also introduced a modified form of parliamentary government by which the prime minister and the Council of Ministers appointed by the president are responsible to Congress and must resign after a vote of no confidence, but it limits the number of times Congress can exercise this power. The president, however, retains much the same wide powers as formerly, comparable to those exercised by the United States executive. He is elected for a four-year term but cannot succeed himself until eight years have elapsed. A vice president is also elected for the same term.

The Congress is divided into a House of Representatives, one representative for every 35,000 inhabitants, and a Senate composed of 54

members, 9 for each province. They are both elected for four years.

The judiciary is composed of a Supreme Court; a Superior Electoral Court; an *audiencia*, or superior court, for each of the six provinces; numerous courts of first instance and other minor municipal courts. The new constitution also provided for the establishment of a Superior Council of Social Defense, but it had not been established up to 1946. Pending its establishment, the penal system is administered by the Ministry of the Interior, in accordance with modern penal practices.

Foreign Relations.—The minister of state is in charge of foreign relations. Cuba was a member of the former League of Nations and joined the United Nations at its inception. She is also a member of the Pan American Union. Cuba's foreign service includes embassies in seven countries, legations in 16, and numerous consular offices in many nations. As in the United States, the Senate must ratify all treaties by a two-thirds vote.

Defense.—The president of Cuba is the commander in chief of the armed forces, which are administered by the Ministry of National Defense. Total army and navy personnel number approximately 20,000. The Regular Army consists of eight line regiments and a cavalry regiment with auxiliary services, and 43 Rural Guard units. During World War II compulsory military service was instituted, but after the war it was abolished. There is a small air force and a navy formed by several gunboats and a number of PT-boats for coastal patrol, as well as detachments of marines.

Public Welfare and Social Legislation.—Public welfare institutions are divided into those directly administered by the Division of Social Assistance of the Ministry of Health, and those which, though incorporated in the division, have an autonomous character. Chief of these is the National Corporation of Public Welfare which supervises all welfare institutions and provides them with funds from government or private sources. Profits derived from the National Lottery are allotted to the various welfare bodies. The Division of Social Assistance runs a eugenics service with eight local centers in different parts of the country and also has charge of the hospital for the insane and an asylum for the aged.

Cuba has a body of social legislation which ranks among the most advanced in the world. The Constitution of 1940 guarantees all workers an 8-hour day and a 44-hour week, with one month's vacation with pay for 11 months of work. Compulsory accident and maternity insurance, as well as other forms of social insurance, are established by law. The minimum wage law established minimum wages for urban and rural workers, which are steadily increasing, rising from \$1 a day for urban workers in 1938, to \$2 in 1944.

Public Health.—Government supervision of public health was greatly stimulated in Cuba after the Spanish American War, under the United States occupation, and has maintained a relatively high standard of efficiency. The Sanitation Department of the Ministry of Health has 126 local sanitation centers scattered throughout the country in the different municipalities in charge of enforcing sanitary measures. It also maintains an inspection service for drug control and milk pro-

duction and, besides the usual health department activities, it maintains a venereal prophylaxis service. Cuba is a member of the Pan American Sanitary Bureau and the World Health Organization of the United Nations.

Provincial and Local Government.—The Constitution of 1940 authorizes three types of municipal government. Up to 1947, however, the only one in operation was the traditional one of an elective mayor, or *alcalde*, and an elected municipal council. The other two types authorized, the city manager system and government by a commission, had not yet been tried.

According to the Constitution of 1940, no other political authority can depose a mayor or otherwise interfere with municipal government, which is granted privileges of taxation and can administer its own affairs, subject only to the authority of the courts. Municipalities provide public services and engage in public works within municipal limits. The municipality is the basic political unit of Cuba. The province represents merely a collection of municipalities within certain geographical boundaries. Although a governor of a province is elected by direct vote, the provincial council is formed by the mayors of the municipalities. The latter contribute corresponding quotas to the provincial budget for public works and other expenses beneficial to the province as a whole.

Way of Living.—Although the overwhelming majority of Cubans consider themselves Roman Catholics, and many, especially the women, are devoutly faithful, the church in Cuba has less social influence than in most Latin American countries and practically no political power. In this respect it can be said to wield less power than in New York and other large United States cities. Nevertheless, the church still represents a traditional social force, aside from its influence on the personal conduct of its followers. Church functions surrounding baptism, marriage, and death, as well as church attendance, are closely interwoven with social habits.

Despite ultraliberal divorce laws and foreign influence, the family is still, as in all Latin countries, the basic and most powerful social institution. Social pressure, the influence of the church, and economic factors all tend to preserve the family unit.

In general, family life is not restricted to parents and children but includes other relatives as well, endowing it with a distinctly clannish aspect. It is not uncommon to find three generations living under the same roof, including married children and in-laws.

Another characteristic which owes its origins to Latin civilization, based on the municipality rather than on the county, is the great importance given to the city or small town as against purely rural life. Despite the fact that Cuba is a predominantly agricultural country, the owners of farms or plantations, at most, spend only a short part of the year on them, preferring to live in the nearby town or the capital, according to their means. This may be owing to the fact that Cubans are a very sociable people. Not only do they constantly visit each other's houses on every possible occasion, but they like to meet continually in clubs, at parties, cafes, shops, and theaters. One out of every three residents in Havana belongs to a club or association of some kind. The smallest towns have their lyceum or casino, centers of social life. The old

custom of everyone congregating and walking around the plaza still lingers.

All sports enjoyed in the United States, except the winter sports, are widely practiced in Cuba. Baseball is highly popular, as well as soccer and basketball, with horse racing, jai alai, and cock-fighting having the added attraction of organized betting. The National Lottery also provides an outlet for the Cuban love of gambling.

Though women have the vote and there is a tendency toward further emancipation, the double standard is still the rule. It is a man's world and young girls, or married women for that matter, do not go out alone with men. This encourages sociability, for the two sexes can meet only in groups.

The upper class has three origins: the old landed Cuban families claiming noble Spanish descent; Cubans who have risen through politics or business since the establishment of the republic; and the more recent Spanish immigrants who acquired wealth in business and the sugar industry. It is this class that lives in the palatial homes in the suburbs of Havana, plays golf and dances in the country club or basks on the yacht club sands. The children are generally sent to expensive United States schools.

The rising middle class, in which the recent Spanish immigration is strong, runs the small businesses, while its older Cuban members run the politics and the government offices and fill the ranks of the liberal professions. The *colonos* or sugarcane growers, if not wealthy enough to belong to the upper group, must also be included. But Cubans are an easygoing people. Class distinctions are not rigid and there is no dividing line between these two classes. There is a steady movement between one and the other, as personal fortunes ebb and flow.

The line between the middle classes and the lowest is more sharply drawn. The latter is formed by the urban and rural proletariat, among whom the colored population predominates on the one hand, and the *guajiro* or peasant, more generally white, on the other.

The *guajiro*, as a distinct class seems fated to disappear, but he has been such a characteristic and essentially Cuban type in the past that he deserves special mention. The *guajiro* is the descendant of the early Spanish settlers who, because of their humble origin and lack of outstanding personal qualities, did not receive the extensive grants of land which formed the basis of the wealth of the prominent colonial families. They settled the small towns and villages of the interior where they acquired small properties or leaseholds from the big landowners. The less fortunate, in time, became tenant farmers or sharecroppers. Among the poorer there was intermixture with the Negro, particularly in Oriente Province, but the typical *guajiro* is white.

The *guajiro* soon developed distinctive folkways. The women wore calico skirts with a colored kerchief around their shoulders; the men wore straw hats with wide upturned brims—Panamas if they could afford them—and pleated linen *guayaberas* (a shirtlike garment hanging loosely over the trousers in lieu of a coat, particularly suited to the climate and now becoming popular even in the cities). The *guajiro* always carried a machete at his waist, a long, straight, wide-bladed weapon. Those who lived on the farms rather than in the villages were the poorer, sharecropper type. This accounts for the preva-

lence of the rickety, palm thatched *bohío*, or peasant shack, in the Cuban countryside and the rarity of well-built farmhouses. Though living in these flimsy and crudely constructed huts, the *guajiro* is still always hospitable to strangers, never failing to greet them with a small cup of coffee, one of his few luxuries.

His typical dish, the *ajiaco*, is a stew containing native vegetables such as yucca and yams, corn, bananas and, if available, beef. Other popular Cuban dishes are black beans and rice; rice with chopped meat, fried bananas and a fried egg; and yellow rice with chicken or pork. A roast barbecued pig is the traditional dish on Christmas. Much of the cooking is done by frying, and garlic and pimento are the condiments most used.

The *guajiro's* favorite pastime is cockfighting, a prize fighting cock being a highly valued possession. The undersized, but wiry Cuban horse is his chief means of locomotion. As in all countries of Spanish heritage, the *guajiro's* chief musical instrument is the guitar. His songs, the rather monotonous *punto* and the melancholy *guajira*, are also clearly of Spanish origin and form the basis of popular Cuban melodies. Equally of Spanish origin are his dances, chief of which was the *zapateado*, a kind of tap dance, now a lost art.

The *guajiros*, illiterate and subject to exploitation in colonial times, were the principal sufferers during the wars of independence. Those who have prospered since then, either through farming or politics, have joined the ranks of the new middle class. The rest, still with a high proportion of illiterates, are in the process of merging with the rural proletariat.

Almost one third of the proletariat, in both town and country, is unionized, thus receiving the benefits of advanced labor legislation and social insurance. The nonunionized, mostly Negroes and poor *guajiros*, have a very low standard of living, though efforts are being made to improve it.

The rural proletariat are mostly workers in the cane fields and sugar mills. Though their lot has been improved by labor legislation, they are plagued by the seasonal character of the sugar industry, which gives them not more than four months' employment out of the year. Whether black or of mixed blood, they have retained their African rhythms which, combined with the *guajiro* melodies, have given popular Cuban music its distinctive stamp. The rumba and the conga originated in the slave quarters of colonial plantations. The real rumba is quite different from the ballroom dance which has been introduced in foreign countries under that name and which in Cuba is called the *son*. In the real rumba, the couple dance separately, representing a primitive version of the battle of the sexes.

CULTURAL LIFE AND ACHIEVEMENT

Education.—Although the University of Havana was founded in 1728 and produced during colonial times a number of outstanding men, education was available only to the privileged few, and illiteracy was high. It was not until 1880 that elementary education was made compulsory, but owing to inadequate facilities, illiteracy decreased slowly. After the establishment of the republic (1902), free public education, nonsectarian in character, was administered by a government department, which in 1940 became known as the

Ministry of Education, and considerable progress was made. In 1943, 22.1 per cent of the population over 10 years of age was still illiterate. In that same year there were 7,516 classrooms, 9,515 teachers, and 371,443 pupils. There were also 140 night schools distributed in the six provinces, and 587 private schools with 71,077 pupils. Many of these private schools are conducted by the Catholic Church. The Ministry of Education also maintains 21 institutes throughout the country, which give secondary education and prepare for the university. It also runs 8 normal schools for teachers and various vocational and industrial schools.

The University of Havana, which is accorded autonomous privileges by the constitution, is divided into the faculties of philosophy and letters, sciences, engineering, architecture, education, sugar industry, law, social sciences and public law, commercial sciences, medicine, dentistry, and veterinary medicine. The student body elects annually the members of the *directorio*, or board of directors, of the Federation of University Students, which plays an important role in the control of university affairs, and frequently in the past has actively participated in the political life of the country.

Libraries.—There were 465 libraries throughout the country in 1943. The oldest one, containing 100,000 volumes, was founded in Havana in 1793 by the Royal Economic Society of Friends of the Country. The National Library was founded in 1901 and contains (1943) 207,423 volumes. The general library of Havana University contains 80,000 volumes.

Press.—Following earlier newspapers, the first important periodical was *El Papel Periódico* which appeared in Havana in 1790. There followed other publications which play an important part in the cultural and political life of the country. The oldest existing newspaper is *El Diario de la Marina*, which was founded in 1834, and which claims to be the oldest existing Spanish language newspaper in the world. Other leading papers having more than 20,000 circulation in 1946 were, *El País*, *El Crisol*, *Información*, *Prensa Libre*, *El Mundo*, *Alerta*, *Luz*, and *Siempre*. Among the weeklies, the two most outstanding are *Carteles* and *Bohemia*. Freedom of the press is guaranteed by the constitution.

Architecture.—The origins of Cuban architecture go back to the 17th century, but it was not until the 18th century that a distinctive style was developed, based on the architecture of southern Spain, influenced by Italian neoclassicism. Good examples of this period can be found in the old section of Havana in residential and government buildings, which were invariably constructed around a central patio featuring arched colonnades. Church architecture, on the other hand, did not attain the importance that it did in Mexico and Peru. In the 19th century a more florid influence was added to the prevailing classicism which gave Havana the appearance, so aptly characterized by Joseph Hergesheimer, of a "mid-Victorian Pompeii." After independence, numerous foreign influences, including North American, made themselves felt, and modern functional architecture was widely adopted.

Painting and Sculpture.—The National School of Fine Arts of San Alejandro was founded early in the 19th century by the French painter Jean-Baptiste Vermay. Aside from its regular courses, its school of applied arts has

special night classes to provide workers with the opportunity for study. There is also a vigorous group of young painters and sculptors who have discarded academic standards and follow the influences of modern masters.

Music.—The degree of serious musical interest in the country is evidenced by the existence of two full symphony orchestras in the capital, the Filarmónica and the Orquesta Sinfónica. Other important musical organizations are the Choral Society of Havana; Pro-Arte Musical, which brings outstanding world artists to Cuba; and numerous smaller societies. There is a municipal Conservatory of Music in Havana and a number of private ones. To meet the popular demand, both symphony orchestras give free concerts in the Municipal Stadium, and the Confederation of Cuban Workers, together with the Popular Concert Society, provide the workers and their families with the opportunity of listening to distinguished artists for a small annual fee.

Although in the past no outstanding musical genius has arisen, there have been many composers of lighter music, and a number of popular Cuban melodies have swept the world. The contribution of the Negro population, marked by its vital rhythmic quality, has been especially developed.

Under the influence of several Russian masters, a very active interest developed in ballet dancing, not unnatural in view of the love of dancing manifested in all sections of the population. An outstanding Cuban ballerina, Alicia Alonso, has won acclaim in the United States.

Literature.—That great age of enlightenment, the 18th century, did not fail to bear fruit in Cuban colonial society. The year 1790, which marks the arrival of the best of the Spanish governors, Luis de las Casas, may be taken as the beginning of a new era of intellectual and moral awakening. The Royal Economic Society of Friends of the Country was founded, which furthered not only the economic but also the cultural life of the colony. Three outstanding educators, José Agustín Caballero (1771-1835), Father Félix Varela (1788-1853), and José de la Luz Caballero (1799-1862), introduced modern currents of thought and succeeded each other at the San Carlos Seminary, at the University of Havana and at El Salvador School, founded by Luz Caballero in 1848. Meanwhile, the 19th century had ushered in two Cubans who laid the basis of a literary movement which helped to mold the growing national consciousness and paved the way for the independence struggle.

José Antonio Saco (1797-1879) was born in Bayamo, Oriente Province. In Havana he soon distinguished himself by his vigorous writings on political economy, history, and literature, and for a time held the chair of philosophy in San Carlos Seminary. But his temperament was too active for an academic existence. As a result of a controversy with the tyrannical Spanish governor, Miguel de Tacón (1777-1855), he was banished from Cuba. At various times, however, he represented the colony in the Spanish Cortes. In his writings he attacked the institution of slavery and became an early champion of the cause of independence. His most important work is an exhaustive six-volume *History of Slavery*.

Greater, from the viewpoint of the Spanish-speaking world, was the poet José María de Heredia y Campuzano (1803-1839). Son of a magistrate in the Spanish colonial service, he was

born in Santiago de Cuba. Early in life embracing the new-born ideal of liberty, he became involved in one of the first conspiracies for Cuban freedom. To escape capture, he fled to the United States, but he had already written *The Temple Pyramid of Cholula*, which has been called "the first romantic poem in the Spanish language." In New York he taught Spanish and published the first edition of his works in 1825, including *Hymn of the Exile* and *Al Niágara* (*Ode to Niagara*), two of his greatest poems, the latter written after a visit to Niagara Falls. Shortly after, he went to Mexico where he established himself, occupied high government posts, and after a brief visit to Cuba, died at the age of 36. His wide vision and the natural spontaneity and richness of his verse, expressive of the romantic sentiments of the age, mark him as one of the outstanding lyric poets of 19th century Hispanic literature, as well as the first great voice of Cuban freedom.

The romantic movement also produced a poetess, Gertrudis Gómez de Avellaneda y Arteaga (1814-1873). Born in Camagüey, her father was a Spanish naval captain and her mother of an old Camagüeyan family. She early revealed precocious literary talents, and at the age of 22 she left for Europe and settled in Spain, where she married and acquired her fame. Her most important work, *Baltasar*, a poetic drama based on a Biblical theme, had a great success in Madrid, and because of its breadth of scope and vigor led a Spanish critic to remark: "This woman is very much of a man!" But she did not forget her native Cuba and one of her finest lyric pieces was written on hearing the news of Heredia's death. After a last trip to Cuba, where she was greeted with great honors, she returned to Spain to end her days. There is no other woman writer of her stature in 19th century Spanish literature.

The poetic development in Cuba was carried on after Heredia by four poets: Gabriel de la Concepción Valdés (pseudonym Plácido, 1809-1844); José Jacinto Milanés y Fuentes (1814-1863); Joaquín L. Luaces (1826-1867); and Juan Clemente Zenea (1831-1870). Two of these, Valdés and Zenea, were executed by order of the Spanish governor because of their activities in favor of independence. Plácido was the abandoned natural child of a Spanish dancer and a mulatto hairdresser. The easy, sensuous music of his verse has made him the most popular of Cuba's poets. Zenea is outstanding as an elegiac poet, though he also wrote vehement, patriotic poems.

In the field of prose, Cirilo Villaverde (1812-1894) wrote a novel, *Cecilia Valdés*, which gives a colorful picture of Cuban life in the mid-19th century. Villaverde was very active in revolutionary conspiracies and died in exile in New York City.

With José Julián Martí (1853-1895), Cuba again produced a creative literary figure who opened new paths for the Spanish-speaking world and became the greatest of Cuban national leaders. Born in Havana of humble Spanish immigrants, José Martí was a forerunner of the *modernista* movement in Hispanic literature, as well as the organizer and moving spirit of the second war of independence which ended with the Spanish American War and the establishment of Cuban independence. The present Cuban republic owes its existence to Martí more than to

any other single man. He remains as one of the greatest men Latin America has produced. Imprisoned at the age of 16 for his espousal of independence during the first rebellion of 1868, he was exiled to Spain, where he studied for a time, later escaping to France, and thence to New York, Cuba, Mexico, and various countries of South and Central America. He engaged in literary work, but always with Cuban freedom uppermost in his mind. Returning to New York, he initiated and carried on a crusade for Cuban independence. In 1895, at the outbreak of the revolution which he had largely inspired, he insisted on accompanying Gen. Máximo Gómez to Cuba and was killed soon after in a skirmish with Spanish troops. Martí's oratorical powers were extraordinary. Like his prose and poetry, they were characterized by the trenchant, original turn of phrase and vivid imagery. In the course of his active career he produced numerous poetical works, very personal in style and couched in novel forms. During a brief lull in the midst of his revolutionary activities, he composed a collection of verses entitled *Simple Songs*, which introduced a fresh and wholly original note into Spanish poetry. Martí's prose works, filling many volumes, affected by his all-consuming devotion to Cuban freedom, do not form a systematic whole. Essays, political tracts, literary criticisms, newspaper articles, biographical sketches—all attest the universality of his vision, the wide range of his interests, and the never-failing spark of genius. Though his style was unorthodox, he was solidly grounded on the great Spanish classics, and he appreciated greatness in others wherever found. The first commentary on Walt Whitman and his poetry in a foreign language was written by Martí in an article published by the Argentine paper *La Nación*, in 1887.

After Martí, most of the modern and ultra-modern poetic movements have been felt and represented in Cuba. Julián del Casal (1863-1893), an aloof and sickly soul, was a fine craftsman, though limited in range. Some contemporary poets have turned to Afro-Cuban themes for inspiration.

The educator, Enrique José Varona (1849-1933), played a creditable part in the revolutionary struggle and became the leading intellectual figure in the young Cuban republic. He reorganized the educational system, served as vice president for one term, and then devoted himself to his writings and to the University of Havana, where he exerted a great influence on Cuban youth. A philosopher of the Spencerian school, he produced numerous works on psychology, sociology, and education, written in an admirably lucid and chiseled prose, which established his reputation throughout the Spanish-speaking world.

Science.—In the field of science Cuba has produced two world figures, Felipe Poey (1799-1891) and Carlos Juan Finlay (1833-1915 qq.v.). Felipe Poey, born in Havana, was a natural scientist famous for his contributions to ichthyology. After a short stay in Paris, where he published numerous scientific articles, he returned to Havana and became professor of zoology and comparative anatomy at the university. In 1863 he was also appointed professor of botany, mineralogy and geology, and later of philosophy. His 10-volume work on Cuban fishes, illustrated with over 1,000 of his own drawings, was his most outstanding work. In it he first made known to science hundreds of varieties of tropical fish. He

also published a geology and a natural history of Cuba. One of his pupils, Dr. Carlos de la Torre (1858—), carried on his work at Havana University.

Carlos Juan Finlay, born in Camaguey of Scottish and French parentage, studied medicine in Cuba and the United States. Dedicating himself to research in yellow fever, which was ravaging Cuba and many other parts of the world, he arrived at the conclusion that this disease was transmitted by a certain variety of mosquito and not by contagion, as was currently believed. He was met with general skepticism, however, and had no means of putting his ideas to a practical test. After the Spanish American War, a United States Army board attempted to eradicate the disease in Cuba but, ignoring Dr. Finlay's conclusions, met with no success. Finally deciding to try out his theory as a last resort, a series of heroic experiments, ably carried on under the supervision of Maj. Walter Reed, proved that Dr. Finlay was right, and one of humanity's scourges was thus conquered.

The Academy of Medical, Physical and Natural Sciences of Havana was founded in 1860 and reorganized in 1923. It has devoted itself in the past principally to the medical sciences. In 1942 a Cuban Society of Physical and Mathematical Sciences and a Society of Chemistry were founded to encourage and develop study and research in these fields.

Medicine and Public Health.—According to the reports of the local sanitation centers in 1943, the three most prevalent diseases in Cuba were malaria, typhoid fever, and tuberculosis. Aside from the Sanitation Department of the Ministry of Public Health, there are a number of institutions, government-sponsored but autonomous in character, to combat these and other diseases. Chief among these in the field of medical research are the Finlay Institute and the National Hygiene Institute. The National Tuberculosis Council seeks to isolate tuberculosis cases, takes care of them in various sanitariums and hospitals, and carries on an extensive educational campaign for prevention of the disease. There is a board of prophylaxis for leprosy, skin diseases and syphilis which also has charge of several hospitals and clinics.

A National Medical Association maintains high professional standards among practicing physicians, and the growth and wide acceptance of socialized medicine has been an interesting development. Beginning at the turn of the century among the Spanish immigrant societies for the benefit of their members, socialized medicine has been adopted by many Cuban institutions and has become thoroughly established. The socialized clinics offer medical care, hospitalization, and surgical operations without cost or at greatly reduced rates, as the case may warrant, for a monthly fee of \$2. See also *LATIN AMERICA*; separate biographies of important cultural figures.

HISTORY

Discovery and Colonization.—Cuba was discovered by Christopher Columbus on Oct. 28, 1492 during the first voyage to what he believed was the continent of Asia. It was not until 1511, however, that Diego Velásquez, appointed governor of the island, which derived its name from the native *Cubanacán*, established the first settlement at Baracoa, on the north shore of what is now the Province of Oriente. In 1514,

after harshly suppressing a rebellion of the native Indians under the leadership of a chieftain named Hatuey, Governor Velásquez brought horses and cattle, grain and other seeds, and agricultural implements, and proceeded inland to found the towns of Bayamo, Trinidad, Sancti Spiritus, and Santiago de Cuba, which became the first capital. In 1515, Puerto Principe (now Camaguey) and Havana (San Cristóbal de la Habana) were founded. The latter was first established on the south coast and was not moved to its present site until 1519. The Indians were by nature pacific; they rebelled only under great provocation, and when reduced to slavery, tended to pine away. Although judged by the standards of the times and in comparison with other conquistadores, Velásquez was relatively moderate in his treatment of the Indians, the race was rapidly being decimated. A Spanish friar, Bartolomé de Las Casas (1474-1566), rose to defend them, returning to Spain to plead their cause before the Council of the Indies. As a result, the outright enslavement of the Indians was prohibited, and the system of *encomiendas* (a kind of trusteeship which was supposed to educate them in the ways of civilization) was instituted. The colonists, however, generally disregarded the educational aspects of the system and continued enslaving the Indians in all but name. Negro slaves began to be introduced in 1523 in small numbers.

Velásquez proved to be a good administrator, but the colony suffered great losses in men and supplies because it had become the base from which the conquering ventures to the newly discovered Mexico set forth, and from which Hernando de Soto launched his ill-starred expedition to Florida and the Mississippi (1539). After Velásquez's death about 1524, there was a struggle for authority between the colonists who held municipal posts and the new governors, a conflict which was to remain in abeyance for three centuries. As the little gold to be had in Cuba had been quickly exhausted, and as there was no silver, the main attention of Spain was directed to other parts of the Americas where great riches were to be found, Cuba being largely abandoned to its own resources.

Age of the Buccaneers.—The capture and sack of Havana in 1555 by the Frenchman Jacques de Sores awakened the Council of the Indies to a new danger and brought back their attention to Cuba. Havana had become the enforced port of call for the fleets of treasure ships sailing to and from the Spanish Main, and its strategic position had shown it to be in truth "the Key to the New World." As a result, Havana was fortified and able military and naval men were sent as governors to defend it against the rapidly growing numbers of French, British, and Dutch buccaneers and corsairs who infested the surrounding sea lanes and repeatedly attacked Cuban towns. This state of affairs continued during the course of the 16th century. The Spanish settlers that had remained and their descendants, who may now be called Cubans, had turned from the search for gold to cattle raising and agriculture. They conducted a thriving legitimate trade supplying the Spanish ships with fresh provisions, and also a contraband trade with foreigners. The British, Dutch, and French (the latter mostly Huguenots), enemies of Spain were enemies also of the Catholic faith; and, though the Cubans were willing to trade with

them, they loyally supported their governor when it was a question of defending the island against foreign heretics. Owing to this state of continual hostilities, the growth of the colony was greatly retarded. Except for some 3,000 Spanish colonists who came from Jamaica when that island was ceded to the British (1655), immigration was greatly restricted. Though sugarcane had been introduced, it was cultivated only on a small scale. Copper also had begun to be mined in a small way.

Eighteenth Century: Period of Internal Development.—In 1697 the Treaty of Ryswick (q.v.) ended the War of the Grand Alliance which had involved Spain, England, Holland, and the Holy Roman Empire on one side and France on the other. This treaty had the indirect effect of ending once and for all the menace to Cuba of the privateers and buccaneers. A period of relative prosperity set in which coincided with the accession of the Bourbon dynasty in the mother country. The new Bourbon rulers reorganized the colonial administration and sent a succession of able governors to carry it out in accordance with the mercantilist theories of the age. Despite the monopolistic restrictions, Havana soon became one of the most thriving ports in the Western Hemisphere. New shipyards were developed and shipbuilding activities redoubled. A group of Havana citizens, headed by Col. Martín de Aróstegui, formed a trading company in 1740 after obtaining a royal charter which gave it a monopoly in the field. The government itself established a tobacco monopoly which in the future was to cause several open revolts of the tobacco growers (mostly *guajiros* belonging to the small farmer class) against its price fixing policy, until it was finally abolished. But if Cuba had been freed from the dangers of piracy, it now faced the consequences of regular warfare. After being threatened several times by British squadrons, toward the end of the Seven Years' War a full-scale expedition under the command of Lord Albemarle, and re-enforced with American colonial troops, attacked Havana in June 1762. After a siege lasting two months with heavy casualties on both sides, Morro Castle fell (August 14) despite the heroic resistance of the Spanish naval captain Luis de Velasco, and Havana surrendered. Havana citizens had aided in the defense and a Cuban from a nearby town, José Antonio Gómez, had organized a guerrilla force of *guajiros* which successfully harried the British forces and captured a number of prisoners. The British exacted a large indemnity from the city; but as they were anxious to develop its commercial possibilities and win over the inhabitants, the British occupation, which ended with the Treaty of Paris (1763), proved to be highly beneficial. Spain recovered possession of Havana in exchange for Florida. As the commercial advantages enjoyed under the British were now continued by Spain, Havana rapidly achieved great prosperity. Extensive fortifications were built which made it the most strongly fortified city in the Western Hemisphere. After the outbreak of the American Revolution, Spain followed her French ally in declaring war on England in 1779, and Havana became the base of operations. As a result, Mobile, Pensacola, and the Bahamas were captured from the British. It was from Havana that the French admiral, Count François de Grasse, sailed to aid in forcing the final surrender at Yorktown. Meanwhile,

by 1774, Havana's population had risen to 76,000, far surpassing that of New York. A series of able and enlightened governors carried out many public works, embellishing the city with parks and handsome buildings, including a theater. Two governors especially distinguished themselves: Marqués de la Torre (served 1771–1777) and Luis de las Casas (1790–1796). Las Casas, wisely counseled by the distinguished Havana citizen, Francisco de Arango, encouraged cultural as well as economic progress. Among the prominent landowning families, several of whom bore Spanish titles of nobility, a new civic spirit was born. In 1793 the Royal Economic Society of Friends of the Country was formed under Arango's leadership, bringing together the outstanding landowners and intellectuals of the colony, helping to mold a national outlook, and taking action for favorable reforms. The municipal government, in the hands of Havana citizens, likewise played an important role. The application of the new process for crystallizing sugar, and free slave trading, authorized in 1791, was to make possible the extraordinary development of the sugar industry, until then a minor enterprise. In the field of ideas, the American and French revolutions had not failed to exert an influence on the educated men of the colony.

Struggle for Independence.—The invasion of Spain by Napoleon, and the placing of his brother Joseph on the Spanish throne in 1808, started a trend of events which in 1810 originated the wars of independence in the South American colonies and in Mexico. There were many reasons why Cuba did not immediately follow their example. Not only was she cut off from the South American mainland, but she rapidly became a base for the concentration of Spanish forces sent to combat the rebels. Furthermore, the high prices prevailing during the Napoleonic wars, the almost complete commercial freedom enjoyed by Cubans, and the rapid expansion of the sugar industry had produced a period of prosperity which was not conducive to revolutionary activity. Moreover, the recent example of the slave revolt in Haiti made the white colonists fearful of the consequences of such action, particularly in view of the increase of the Negro population resulting from the importation of great numbers of slaves. There was also a large influx of Spaniards in Havana seeking refuge from the rebellious colonies, and they were naturally sworn enemies of independence. In 1817 a number of Spanish immigrants were granted plots of land and settled in the country. In 1818 free trade with foreigners was officially authorized. Nevertheless, the spirit of liberty was not to be denied. As early as 1822 a secret society formed along Masonic lines was organized, with the view of ultimate independence. Among the members was a young poet, José María de Heredia. Discovered by the authorities, Heredia escaped arrest by fleeing the country, but his poetical works, filled with the romantic ideal of freedom, inspired the new generation. The year 1823 saw the end of the short-lived constitutional regime in Spain which had allowed Cubans considerable liberties, aside from a certain degree of autonomy which they had always enjoyed. The triumph of absolutism was reflected in Cuba by the assumption of unlimited dictatorial powers by the governors general (1825). Freedom of the press was abolished, and in 1834 this new state of things was made permanent under the tyrannical Governor

Miguel de Tacón. These harsh measures only produced more numerous conspiracies. In March 1826, Francisco de Agüero, a youth belonging to a well-known Camagüeyan family, was executed because of his revolutionary activities, becoming the first of a long list of martyrs to the cause. Two Cuban delegates proceeded to Colombia to interview Simón Bolívar, the great leader of the South American wars of independence, who, having triumphed there, was planning to lead an expedition to free Cuba as well. The plan was never carried out owing to internal difficulties faced by Bolívar, and also due to the opposition of the United States, which feared that a Cuba freed from Spain might fall into the hands of England or France and thus become a dangerous threat. In 1837 and 1844 two more conspiracies were discovered by the colonial authorities, and the popular poet Gabriel Valdés (Plácido), along with many others implicated in the latter plot, was executed. The writer José Antonio Saco condemned the institution of slavery and, forced into exile by Governor Tacón, demanded independence. Meanwhile Narciso López, a Venezuelan by birth, had initiated revolutionary efforts. In May 1850 he led an expedition to Cuban shores, and failing then, he organized another revolt in August 1851 in which he was accompanied by a group of United States citizens. Not meeting with the expected support, López and most of the other members, after putting up a brave fight, were captured and shot. These expeditions had not had sufficient backing within Cuba itself to have a chance to succeed. The Spanish merchant class in Havana, whose interests were opposed to those of the Cuban landowners, were the worst enemies of independence and urged the governors on to harsher repressive measures. As a result, even the more moderate Cubans, who would have been satisfied with reforms granting Cuba fuller autonomy, began to favor outright independence, though some desired annexation to the United States. Secret conspiracies rapidly extended their ramifications throughout the island.

The Ten Years' War.—On Oct. 10, 1868, a landowner and lawyer of Oriente Province, Carlos Manuel de Céspedes, gathering a resolute band around him, freed his slaves and initiated the rebellion at the village of Yara. Revolutionary groups in neighboring Camagüey Province also took the field soon after, led by the titled landowner Salvador Cisneros y Betancourt (the Marqués de Santa Lucía) and the dashing Ignacio Agramonte. In the western provinces, too near the center of Spanish power in Havana, the insurrection did not achieve the same success, and many of its backers were forced to flee to the United States. Among them was Miguel Aldama, one of the wealthiest citizens of Havana, whose palatial residence is still one of the show places of the city. Aldama's properties were confiscated and he gave most of what remained to the cause. Another wealthy backer of the revolt was Francisco Vicente Aguilera, of Bayamo, Oriente. Owner of vast landholdings, he was later sent by the revolutionary government to represent it in New York, where he died penniless. Meanwhile, the leaders of the insurrection proclaimed the independence of Cuba, drew up a constitution modeled on that of the United States, and elected Carlos Manuel de Céspedes president (1869). Many *guajiros* and Negroes joined the rebel forces and the outstanding military leader was the Camagüeyan Ignacio Agramonte. After ini-

tial victories in several pitched battles, the revolutionary forces, undisciplined, lacking arms and supplies, and faced by superiorly equipped Spanish troops, endured untold hardships. Before he was killed in action in 1873, Agramonte successfully organized a cavalry force which, under Máximo Gómez y Báez who succeeded him, gave a good account of itself in many engagements. In 1874, Céspedes, who had been forced to retire from the leadership because of internal dissensions, was captured and shot. But shortly after, Gómez, with 1,300 infantry and 300 cavalry defeated a superior Spanish force at Las Guásimas, the Spaniards leaving more than 400 dead on the field. That was the last victory of the rebellion. Spain continued to pour re-enforcements into the island. The United States government, though sympathizing with the rebels, was unwilling to grant them belligerent rights. Finally the diplomatic Spanish Gen. Arsenio Martínez de Campos was able to conclude the Convention of El Zanjón, Feb. 10, 1878, promising reforms and a greater degree of autonomy. A precarious peace followed and the promised reforms were watered down, though in 1886 the institution of slavery was finally abolished. The Cubans in the eastern provinces had suffered heavily. Whole families had been wiped out and great damage had been inflicted on the sugar properties. Many Cubans emigrated to the United States and no other major revolutionary effort seemed possible.

Revolution of 1895.—An extraordinary man, José Julian Martí, now appeared on the scene. A brilliant orator, a writer and poet of great force and originality, with single-minded devotion to the cause of liberty, he rekindled the revolutionary spirit. In 1892 he founded the Cuban Revolutionary Party while living in exile in the United States. Rallying the military leaders of the previous insurrection, he raised funds, organized expeditions, and on Feb. 24, 1895, open rebellion broke out again at Bairé. Martí issued a manifesto to the Cuban people establishing the basis of the present Cuban republic, and insisted on accompanying the rebel General Gómez in his perilous landing on Cuban shores. Inspiring the patriot forces with his words and example, Martí was killed soon after, during an engagement with the enemy at Dos Ríos. On Sept. 13 1895, a revolutionary government was organized with Cisneros y Betancourt as president. General Gómez and his principal lieutenant, Antonio Maceo, who had defeated a Spanish force at Peralejo, almost capturing the Spanish general, Martínez de Campos, now determined to carry the war to the western provinces. A plan of invasion was drawn up and initiated at Baraguá, Oriente, in the month of October. Proceeding with great mobility, after fighting numerous engagements and defeating a Spanish column at Mal Tiempo, in Las Villas, the rebel forces entered Havana Province and reached the outskirts of the city in January 1896. Gómez then returned to a central position to maintain hostilities there, while Maceo with part of the forces, went on to Pinar del Río Province and reached the westernmost town of Mantua shortly after in a brilliant guerrilla campaign. In spite of their great superiority in men and equipment, all Spanish efforts to trap Gómez and Maceo proved futile. Determined to stamp out the rebellion at all costs, the Spanish government sent over 100,000 troops to the island and appointed Gen. Valeriano Weyler Nicolau to carry out a ruth-

less policy. Great numbers of the rural population were herded into concentration camps; stern reprisals were adopted against all suspected of rebel sympathies, and there was great destruction of property on both sides. Maceo was killed in an action in Havana Province in December 1896, but Gómez in the center and Calixto García in Oriente managed to keep up the resistance in spite of the overwhelming odds against them. Meanwhile, public opinion in the United States, naturally favoring the rebels, and fanned by the Cuban revolutionary junta in New York, had been aroused by the harsh Spanish policy.

Spanish American War.—As a result of United States protests, a new Spanish government attempted to inaugurate a conciliatory policy. General Weyler was recalled to Spain, and Gen. Ramón Blanco was sent as governor general with instructions to offer the autonomous regime which had previously been asked by moderate Cubans. But it was too late. The offer was rejected by the rebel leaders, who would accept nothing less than full independence, and was violently opposed by the Spanish merchants, who would not tolerate the slightest concessions to the Cubans. In view of the disorders promoted by them in Havana, United States Consul Fitzhugh Lee requested a naval force to protect American lives and property. The United States battleship *Maine* (q.v.) was sent in January 1898, and feeling against Spain was heightened in the United States by the publication in the press of a private letter written by the Spanish minister in Washington, which contained uncomplimentary references to President William McKinley. On the night of February 15 the *Maine* blew up in Havana harbor, with the loss of 260 members of the crew. Public opinion naturally blamed the event on the Spaniards. President McKinley on March 27 sent a virtual ultimatum to Spain demanding the cessation of the concentration camp policy, and the conclusion of an immediate armistice with the insurgents. The Spanish government agreed to the first but delayed acceptance of the second, offering Cubans an autonomous status similar to Canada's. On April 11, President McKinley sent a message to Congress proposing armed intervention to end the conflict. On the 19th, Congress passed a joint resolution empowering the president to employ the armed forces to that end, at the same time asserting that "Cuba is, and of right ought to be, free and independent," and demanding that the government be turned over to the Cuban people. On April 20, President McKinley signed the resolution and two days later he ordered the blockade of Cuba, thus initiating hostilities.

The Spanish American War was soon ended. (See UNITED STATES—*The War With Spain*.) A Spanish fleet under Admiral Pascual Cervera was destroyed off Sanitago de Cuba July 3, and the city of Santiago surrendered to a joint American-Cuban land force on July 17. On August 12, the armistice was signed, providing among other things for immediate evacuation of Cuba by Spanish forces. The last of the Spanish troops were withdrawn from the island Jan. 1, 1899. Meanwhile, in the peace treaty signed in Paris Dec. 10, 1898, Spain relinquished all claims to Cuba. The Spanish negotiators urged American annexation of the island to protect Spaniards residing there, but this proposal was rejected, and the treaty provided merely for temporary occupation by United States forces. This was considered neces-

sary to effect an orderly transition to independence and to meet the emergency presented by widespread starvation and disease.

Military Occupation.—The American military occupation of Cuba lasted from the end of the war until May 20, 1902. During this period the island's affairs were administered by a United States military governor, the office being filled by Maj. Gen. John R. Brooke (Dec. 28, 1898–Dec. 20, 1899) and by Maj. Gen. Leonard Wood (Dec. 20, 1899–May 20, 1902). With the aid of a few Americans and of Cubans, who filled the great majority of public offices, General Wood performed outstanding service in preparing the island for independence.

He reorganized the old corrupt and inefficient colonial administration and reformed the courts, though wisely preserving the Spanish legal system, as well as other existing institutions which represented a sound traditional force. He initiated a modern highway system, introduced efficient sanitation, reorganized and greatly extended educational facilities, and rehabilitated the island's primary economic enterprises. Under his administration the scourge of yellow fever was eliminated. Meanwhile, elections were held for delegates to a constitutional convention which met in Havana, November 1900 under the presidency of the venerable Cisneros. It drew up a constitution (adopted Feb. 21, 1901) largely modeled on that of the United States. When the Platt amendment was adopted by the United States Congress (March 2, 1901), giving the United States the right to intervene in Cuba for the preservation of its independence under certain conditions, the convention at first refused to incorporate it into the Cuban Constitution. It finally did so reluctantly on June 12 after a commission sent to Washington was assured it did not impair Cuba's sovereignty and that further economic assistance depended on its adoption. By it the United States also acquired rights to establish naval bases at Guantánamo and Bahía Honda. General elections were then held in December 1901 and in February 1902; Tomás Estrada Palma was elected first president of the country. The first Cuban Congress convened early in May. On May 20, 1902, which has become Cuba's Independence Day, General Wood formally surrendered his executive powers to President Estrada Palma, and United States military occupation was officially ended.

The Cuban Republic.—President Estrada Palma was a good, honest administrator, but he lacked the personal qualities that distinguish a political leader. Not trusting his popularity, when his first term expired, he allowed his Cabinet members to use any means to ensure his re-election. This brought on the armed revolt of the opposing Liberal Party which led to United States intervention, and a provisional United States government (1906–1909) under Charles E. Magoon. In the elections held on Nov. 14, 1908, under the supervision of the Magoon administration, José Miguel Gómez, the Liberal Party candidate, triumphed, assuming office in January 1909. From that time, until and including the election of Gerardo Machado y Morales in 1924, the Liberal Party was the majority party. Gen. Mario García Menocal, the Conservative Party leader, won the election in 1912 owing to a split in the Liberal Party when Dr. Alfredo Zayas formed the Popular Party. The ideological differences between the Conserva-

tive and the Liberal parties were even less than those between the Republican and Democratic parties in the United States. They both adopted a laissez faire economic policy, and Cuban history during that period was largely taken up by the rise and fall of sugar prices, and the domination of the sugar industry by foreign interests (see section on *Sugar Industry*). Politics was almost entirely in the hands of professional politicians. It is not surprising that political malpractices developed where there had been no free political institutions before; where a large proportion of illiteracy still prevailed; and where four centuries of autocratic colonial rule had conditioned Cubans to regard the government as an institution divorced from their private lives, subject to arbitrary control and inevitably corrupt. President Menocal's re-election (1916) was accompanied by charges of fraud, provoking another Liberal Party revolt which was unsuccessful. Following the end of his second term, Dr. Alfredo Zayas was elected with General Menocal's backing (1920). This was during the great sugar boom which was known as the dance of the millions, accompanied by wide demoralization. Gen. Gerardo Machado y Morales, the Liberal Party candidate, won the following election by a large plurality (1924). President Machado during his first four-year term gave Cuba an efficient government. He introduced much-needed reforms in the administration, carried to completion numerous public works, such as the Central Highway, and initiated the protection of Cuban industry. But the collapse of the sugar boom revealed his dictatorial tendencies. Personal ambitions led him to change the constitution (1928) in order to prolong his term of office, as well as to employ terroristic methods to destroy all opposition, discrediting him among a growing group of the non-political public. University students and professors originated the opposition, and an unsuccessful open revolt was followed by an underground campaign of terrorism which claimed many victims on both sides, proving that Cubans were still ready to fight and give their lives for freedom. A secret society known as the ABC was formed to combat the government, its leaders drawn from the young professional class, and the acute economic depression widened the general opposition. President Machado responded with harsher repressive measures and finally, in 1933, the newly arrived United States Ambassador Sumner Welles attempted to mediate between the government and the opposition. A well organized general strike followed by withdrawal of the army's support, resulted in the violent overthrow of General Machado (Aug. 12, 1933), who escaped by plane. A provisional government with Carlos Manuel de Céspedes, son of the former patriot, at the head, was formed with Ambassador Welles' blessing, but less than a month later (September 4) an army mutiny, led by the then Sergeant Fulgencio Batista y Zaldívar, and supported by the university students and a group of intellectuals and professionals, overthrew Céspedes and placed a revolutionary council of five in his stead. Soon after, Dr. Ramón Grau San Martín was appointed president and Sergeant Batista rose to be colonel and commander in chief of the army. Led by Dr. Grau San Martín, a new party, the *Revolucionario Cubano*, was formed, demanding "Cuba for the Cubans" and attacking "Yankee Imperialism."

Although rejecting communism, it enforced an 8-hour law and other legislation favoring native-born workers. The United States refused to recognize the Grau San Martín government, and after weathering an attempted revolt, he lost the support of some of his party and of Colonel Batista, resigning in January 1934. Col. Carlos Mendieta, a veteran of the war of independence who had the support of the traditional parties was then installed in office. The United States abrogated the Platt Amendment and a new trade treaty was negotiated. There followed a seven-year reign of provisional governments and temporary presidents, with Colonel Batista, as head of the army, wielding the real power. Nevertheless, the new policy of economic nationalism was continued by means of legislation such as the Law of Sugar Coordination (see section on *Sugar Industry*), and a program of public works was carried out under army auspices. Accused at first of Fascist tendencies, Colonel Batista won over the newly established Communist Party, aiding it to organize politically, and thus obtained labor backing. Constitutional government was restored when a Constituent Assembly was freely elected in which all parties were represented (Nov. 15, 1939), and a new constitution was drawn up and promulgated on Oct. 10, 1940 (see section on *Government*). Colonel Batista organized the *Coalicón Socialista Democrática*, formed by the Liberal Party, a part of the Conservatives called *Demócratas*, the *Socialista Popular* (Communist) and various smaller parties, and ran for president. He was opposed by Dr. Grau San Martín, who in turn was backed by the new *Revolucionario Cubano* Party, the remainder of the Conservatives (*Republicanos*) and other small parties. Batista won (July 1940), and though the opposition claimed there had been frauds, the elections on the whole seemed fair to most impartial observers. Soon after assuming office, President Batista legalized the CTC (*Confederation of Cuban Workers*), which was largely controlled by the Communist Party, and had assumed the leadership of all Cuban unions. Government revenues were substantially raised to meet a budget deficit by new taxes, including, for the first time, an income tax, and in December 1941, Cuba declared war on the Axis powers. Compulsory military service was instituted, though Cuban forces were not sent overseas. The government cooperated in the war effort by providing facilities for air and naval bases needed by the United States, increasing production of war materials and aiding in the anti-submarine campaign. At the expiration of his term, Batista, respecting the constitutional provision against re-election, backed for president Dr. Carlos Saladrigas, a lawyer and former leader of the ABC secret society, who had been his prime minister. Opposing him was Dr. Grau San Martín. Saladrigas was supported by the same coalition of parties, which had elected Batista, but Dr. Grau San Martín, also with the same support, won by a substantial plurality. His surprising strength was accounted in part, in addition to his popular following, as a protest vote by the general public against existing high prices and to the desertion of many liberals from the coalition owing to dissatisfaction with the imposition of Dr. Saladrigas' candidature. In any case, both Batista and Saladrigas accepted the results of the election and refused to countenance an attempted use of force by one

of their supporters, Gen. Manuel Benitez. Once in office Dr. Grau San Martín reorganized the army to curtail its political influence. To obtain a Congressional majority for his policies he made a deal with the Communists. Despite record heights of government revenues and budgetary spending, his administration disappointed many supporters who felt that he had made a poor choice of Cabinet ministers and was lax in law enforcement. In the 1948 elections Sen. Carlos Prío Socarrás of the Auténtico Republican Alliance won the presidency; but his three competitors, of the Democratic-Liberal coalition, People's Party, and Communist Party, polled more votes. Though he showed energy in combating Communist intrigues, President Prío was unable to stem the tide of political violence. Former President Batista (now a major general) seized power by a coup d'état on March 10, 1952 and declared himself provisional president. In October 1953 he announced presidential elections for a year later. The opposition candidate at the Nov. 1, 1954 elections was former President Grau San Martín. Alleging that the elections were rigged by Batista, Dr. Grau withdrew from the race two days before the vote and asked his supporters to boycott the contest which was won by the incumbent. About 50 per cent of the eligible voters went to the polls.

MARTÍN ARÓSTEGUI,
Former Publisher and Editor, "The Havana P.M."

CUBA, village, N. Y., in Allegany County; altitude 1,500 feet; 12 miles northeast of Olean; on the Erie and Pennsylvania railroads. Industrial activity centers chiefly upon the production of cheese, electrical specialties, and boxes; the surrounding region is one of dairy and poultry farms. North of the village is Cuba Lake, popular locally as a resort. Cuba Reservation, at the southwestern tip of the lake, includes what is reputed to be the first petroleum spring discovered in America (1627). Pop. (1940) 1,699; (1950) 1,783.

CUBE, in geometry, a solid contained by six equal square sides. The content of a cube is found by multiplying the superficial area of one of the sides by the height; or, in other words, by multiplying the number that expresses the length of one of the edges by itself, and the product thus found by that number again, and this is called the cube of the number. A cube is generated by the motion of a square plane along a line equal to one of its sides, and at right angles to it; whence it follows that the planes of all sections parallel to the base are squares equal to the base, and consequently to one another.

CUBE, or **CUBIC NUMBER**, in arithmetic, the result of taking any number thrice as a factor; thus 64 is a cube number, and arises by multiplying 4 by 4 and the result again by 4.

CUBEB, ku'béb, the fruit of *Piper cubeba*, a climbing perennial with smooth stem and alternate lance-shaped, bright green, shining leaves. It is a native of the East Indies, being extensively cultivated in Java and Sumatra. It was introduced into medicine by the Hindus and Arabians, who employed it widely as a condiment also. Cubebs contain about 14 per cent of volatile oil, a small amount of an indifferent substance termed cubebin, and cubebic acid. They also contain a small amount of resin. A mixture of oils, resins and acids composes the oleoresin of cubebs that is used in medicine. It is an active spice somewhat related to pepper, its botanical ally, but the taste is more pleasant and less pungent. It is used as a local stimulant in indigestion and as a flavoring vehicle in mixtures and gargles. It is valuable, particularly in diseases of the mucous membrane, especially of the bronchi, of the bladder and of the urethra. Cubebs are very frequently smoked in cigarettes, in which form they have a pleasant stimulating effect on the mucous membrane of the bronchi and larynx.

CUBIC EQUATIONS, equations in which the highest exponent of a given quantity in any term is 3. Every such equation of one unknown quantity can be reduced to the form $x^3 + px + q = 0$, where x is the variable and p and q are constants. Every equation of this form has three roots, all of which may be real, or one may be real and two imaginary. The solution of cubic equations was accomplished first by Tartazlin and Cardan. An equation containing any number of variables in which the greatest sum of the exponents of the variables in any term is 3 is called a cubic equation. Thus $x^2y + 5y^3 + 6 = 0$ and $xyz + x^2 = 0$ are cubic equations in x , y , and x , y , z , respectively.

CUBISM, the name given to a movement in painting which began in Paris about 1910 and spread throughout the world, influencing the painting and sculpture of the 20th century, as well as its architecture and decorative arts. The leaders were Pablo Picasso and Georges Braque, and other members of the group included Albert Gleizes, Juan Gris, Roger La Fresnaye, Henri Laurens, Fernand Leger, Jean Metzinger, and Marcel Duchamp. The more thoughtful members of this group held that painting should not be a literal or realistic representation of nature, but that an object should be presented in terms of intersecting, often transparent, cubes, cylinders, and other geometric forms or figures. Thus represented, the object might lose its identity, but this was unimportant because the beauty and meaning of a work rests in the work itself and not in the subject with which it begins. This was the first analytical phase of cubism. Later, however, the principle of simultaneity developed—that is, an object was presented from different points of view in the same picture—and cubism entered its synthetic phase. Collages were used—pieces of paper or other material which were pasted on the canvas to become an essential part of the painting. As form and color were held to be one and inseparable, color became duller. Movement and modeling in depth were eliminated.

and pictures tended toward two-dimensional design. In the hands of some of its followers the concepts of the movement became somewhat obscured and cubism merged with futurism (q.v.). See also FRANCE—*Art and Architecture* (The 20th Century).

CUBIT, kû'bīt, an ancient measure of length. Approximate only, it applied to the length from the elbow to the tip of the longest finger. The Hebrews had two cubits—the ordinary cubit, and a longer one used by Ezekiel in his measurements for the Temple (Genesis 6:16; Deuteronomy 3:11; II Chronicles 3:3; 4:3; Ezekiel 43:13). Estimates vary between 16 inches and 25.2 inches. The Egyptian common cubit was about 17.72 inches; the royal cubit 20.67 inches.

CUBITT, Sir William, English civil engineer: b. Dilham, Norfolk, England, 1785; d. Clapham Common, Surrey, Oct. 13, 1861. He constructed the South-Eastern Railway (England) and the Berlin, Germany, waterworks, and was the engineer on many other important undertakings in England and on the Continent. His work in connection with the buildings erected in Hyde Park for the great exhibition of 1851 won him a knighthood.

CUCHIA, kōō'chī-ā, a teleost fish of the rivers and estuaries of India and Burma, growing to two feet in length. It is the sole representative of the family Amphipnoidae, and is remarkable for having on each side of the neck a respiratory air sac connected with the gill cavity. When in the water this amphibious fish constantly rises to the surface to breathe air, and is frequently found in the grass of the river bank.

CUCHULAINN or **CU CHULAIN**. See GAELIC LITERATURE; TAIN BO CUALNGE.

CUCKOO, kōōk'ōō, the English name of a well known European bird (*Cuculus canorus*), so named from the call of the male, copied in the "cuckoo" clock. About 14 inches in length, the cuckoo is plain gray on throat, breast, and back; the belly is white barred with grayish black. Young birds are rust colored above, barred heavily with brownish black, the underparts barred from head to tail. Celebrated since the time of Chaucer for its loud song, so noticeable in the English countryside in May, the cuckoo is an object of some mystery because of its parasitic nesting habits. The hen cuckoo invariably lays her eggs in the nests of small songbirds such as the meadow pipit and the hedge sparrow. Hence the word "cuckold" for a man whose wife goes to another's "nest."

The egg of the cuckoo is very small for the size of the bird, and sometimes resembles that of the host species in color. Eggs similar to those of the host in size and color are more apt to be accepted and hatched, and hence selection favors such eggs. It was once believed that the hen cuckoo lays her egg on the ground and then with her bill places it in the nest of her victim. It is now known that she lays her egg in the usual manner in the nest. Often, however, she does remove one of the eggs of the rightful owners of the nest with her beak. The young cuckoo, as soon as it hatches and before its eyes are open, with unfailing instinct works beneath the

other occupants of the nest, and then by rising up pitches them over the side of the nest to their death. Left in sole possession of the nest, it soon exceeds its small foster parents in size. Sometimes one sees a bulky young cuckoo fed by tiny warblers, which actually perch on the head of their gross "stepchild" to feed it.

Most of the numerous species of the family Cuculidae (q.v.) are called cuckoos of one kind or another. Many of the Old World species, but only one or two in the New World, share the parasitic nesting habits of the common cuckoo of Europe. Some of the parasitic species of Asia mimic small hawks. Presumably when such cuckoos approach the nest of a small bird to lay their egg, the rightful tenants are intimidated or frightened away.

The two common cuckoos of the United States, the yellow-billed (*Coccyzus americanus*)

Yellow-billed cuckoo

and the black-billed (*C. erythrophthalmus*), resemble the European cuckoo but are somewhat smaller and lack the barred underparts. Like most cuckoos they are slender, graceful birds, which slink rather furtively through thick vegetation and are more often heard than seen. They build a flimsy nest; sometimes the three or four bluish eggs are visible through its bottom. The voice of the American species is resonant and full bodied, but the syllables uttered do not resemble the word "cuckoo." Country people think they call most loudly before a summer storm and name them "rain crows." The road runner (q.v.) of the deserts of Mexico and southwestern United States is also a cuckoo. Called *paisano* by the Spanish speaking people, it is well known for the speed with which it dashes across the desert in pursuit of lizards and small snakes.

The American Museum of Natural History.

CUCKOO AND THE NIGHTINGALE, The poem by Sir Thomas Clanvowe, English 11th century poet. The poem was long attributed to Geoffrey Chaucer. It is an important link between 14th and 15th century English poetry because of the apparent careful study Clanvowe had made of the writings of Chaucer.

CUCKOO BEE, the name given to numerous solitary bees, especially of the family Nomadidae, which lay their eggs in the nests of other bees, make their homes there, and eat the food of their hosts, with whom they live harmlessly. The females do not sting severely.

CUCKOO FLY, a species of the hymenopterous family Chrysididae which, cuckoolike, live

at the expense of various solitary bees and wasps, but, unlike the cuckoo bee (q.v.), actually devour the young of their hosts. They may be seen on hot days briskly flying about and alighting on posts and trees, darting their ovipositors into holes in search of the cells or nests of other Hymenoptera, to lay their eggs in. After hatching as maggots they feed on the pollen stored up by the host. More often they are known to fasten on the back of the larva of their host, suck its blood and thus destroy it; they also appear to destroy the eggs of their host. Although the *Chrysis* lays from 6 to 10 eggs, all but one shrivel up. It has been noticed that the young larva seizes with its mouth parts a fold of the skin of the helpless larva of the wasp *Odynerus* and sucks it, without inflicting any visible wound. It spins its cocoon inside that of its host, remaining there until the following spring. Cleptidae, another species of the same family, are supposed to prey on sawflies, probably laying their eggs in the cocoons of the latter.

CUCKOO PINT, the common name for *Arum maculatum* of the family Araceae. It grows about a foot high and has arrow-shaped, polished leaves, black spotted, and a flower bract (spathe) resembling that of the calla, but edged with green and sometimes purple.

CUCKOO SPIT, a froth found on plants. It is a secretion of the larvae of small homopterous insects, of the family Cercopidae. It serves the purpose of concealing the larva from its enemies. See also FROGHOPPERS OR FROTH FLIES.

CUCKOOFLOWER or **LADY'S SMOCK** (*Cardamine pratensis*), a common meadow plant, family Cruciferae, whose white or rose-purple flowers, borne in a corymb, may be seen from April to July, growing in masses in swamps and wet meadows from Labrador to northern New Jersey, in Minnesota, and west to the Pacific coast of British America. It is also common in northern Europe and Eurasia.

CUCUJO, kōō-kōō'hō, or **CUCUYO**, kōō-kōō'yō, a luminous beetle of the click beetle family Elateridae, which, in the West Indies, Mexico, and northern South America, is often used as an ornament in the hair or upon the dress of women. The Indians capture them by waving about a stick to which they have attached a coal; the beetles are attracted by the light and may then easily be caught in nets. The Indians keep them in cages of wire netting, feed them each evening upon pieces of crushed sugarcane, and bathe them twice daily in tepid water. In this condition they are offered for sale in large numbers in the shops and street-markets of Veracruz and other tropical cities. The principal species (*Pyrophorus noctilucus*) is from one and three quarters to two inches in length, and has no beauty by daylight, being rusty brown or blackish; but when belted and attached to a pin in the hair by a delicate chain it glows at night like an immense gem.

CUCULIDAE, kū-kū'li-dē, the cuckoo family, the principal one of the order Cuculiformes. The toes are paired, the first and fourth being directed backward, the second and fourth forward. The family contains about 130 species, chiefly tropical, but a few extend far north in
